both natives of S. Eu., where they have been studied by several botanists, some of whom distinguish them by various characters, while others unite them into a single species. J.G. Baker considers *R. Hypoglossum* a variety of *R. Hypophyllum*, differing in having the costa under the cluster of fls. in the form of a large leafy bract lacking entirely the texture of the phyllodium. In B.M. 2049, *R. Hypophyllum* is shown with minute white fls. and handsome red berries nearly $\frac{1}{2}$ in. thick.—*R. racemobus*, Linn.=*Danaë racemosa*, Moench.

F. TRACY HUBBARD.†

RUSH: *Juncus*. Flowering *R.*: *Buto-*
mus. *R. Lily*: *Sisyrinchium*.

RUSSELLIA (in honor of Alexander Russell). *Scrophulariaceae*. Shrubs with angled, usually slender and often pendulous branches, grown in the warmhouse for their showy flowers.

3511. *Ruscus aculeatus*. Leaves opposite or verticillate, usually small, reduced to scales on the branches: fls. in bracteate dichotomous cymes, either laxly or densely many-fld., sometimes reduced to a single fl., red; calyx deeply 5-cleft or 5-parted, segms. strongly imbricate; corolla-tube cylindrical, limb somewhat 2-lipped, 5-cleft, the lobes all rounded; stamens 4, didynamous: caps. subglobose, septically dehiscent, valves 2-cleft.—About 20 species, Mex. and Cent. Amer. A synopsis of *Russelia* by B. L. Robinson, with a key to the species, will be found in Proc. Amer. Acad. Arts. & Sci., vol. 35, No. 16, March, 1900.

Russelias are of easy cultivation. *R. juncea* and its varieties make excellent basket-plants, being almost continuously in bloom. Propagated by cuttings.

A. Peduncles 1–3-fld.

júncea, Zucc. (*R. scoparia*, Hort.). CORAL PLANT. Fig. 3512. A tender shrubby plant, with smooth, somewhat rush-like branches, nodding or pendulous at the top: lvs. linear-lanceolate or ovate, small, becoming minute bracts on the branches: raceme very loose, remotely fld.: peduncles elongated. B.R. 1773.

P.M. 4:79. G.W. 5, p. 379. Var. *semperflorens*, Hort., has been mentioned. Gt. 1:5.

Lemoinei, Hort. (*R. juncea* var. *Lemoinei*, Hort.), is a garden hybrid between *R. juncea* and *R. sarmentosa*, said to be more floriferous, especially during the winter, than the parents.

elegantissima, Hort. (*R. juncea* var. *elegantissima*, Hort.), is another product of the same cross as the above and said to have similar characters.

AA. Peduncles many-fld.

sarmentosa, Jacq. (*R. multiflora*, Sims). A tender shrub, becoming 4–6 ft. high: lvs. opposite, ovate, acuminate, serrately crenate: fls. verticillate, many in a terminal raceme, bright red, erect or drooping, about $\frac{1}{2}$ in. long. B.M. 1528. P.M. 16:163. R.H. 1852:281. R.B. 25:61.

F. TRACY HUBBARD.†

3512. *Russelia juncea*. ($\times \frac{1}{4}$)

RUSTS. The plant rusts are fungi constituting the large and well-defined order Uredinales, which contains approximately 3,000 species distributed in about forty genera. They are all obligatory parasites, mostly on angiosperms, few on gymnosperms, and a small number on ferns.

Relations between host and parasite.

The mycelium of the rust fungi (see *Fungi*) lives symbiotically within the tissues of the host. It is generally confined to the intercellular spaces, but short branches or haustoria penetrate the cells and absorb nutriment from them. Usually not more than one or two haustoria are found within a single cell and only a small proportion of the host cells are thus invaded, although the mycelium itself is abundant in the intercellular spaces.

The extent to which the mycelium spreads within the tissues of the host and its duration of life vary greatly with different species of rusts. In most of the species which inhabit annual parts of plants, as leaves and stems, the mycelium resulting from individual infections is localized within a more or less restricted area, as in case of hollyhock rust, carnation rust, and wheat rust, and generally persists as long as the infected parts remain alive. That plants thus infected nevertheless become completely covered with rust spots is attributable to the large number of separate infections which occur and not to the spreading of the mycelium through the whole plant. When biennial or perennial parts are locally infected, the mycelium often persists for two years, as in the rust of the red cedar, *Gymnosporangium globosum* and *G. juniperi-virginiana*, or becomes perennial, as in the rust of juniper, *Gymnosporangium clavariæforme*, and the blister rust on stems of pines, *Peridermium cerebrum*. Many rusts have mycelia which extend throughout the tissues of the host. This type of mycelial distribution is characteristic of the orange rust of the species of brambles, *Gymnoconia interstitialis*, and of a number of rusts infecting herbaceous perennial plants, as the rust of Canada thistle, *Puccinia suaveolens* and the pea rust (*Uromyces pisi*) on the cypress spurge (*Euphorbia Cyparissias*). In such cases the mycelium of the fungus remains dormant in the rhizomes or in the roots and in spring grows out into the developing shoots which are usually characterized by spindling growth

with long internodes and small and somewhat deformed leaves. Shoots which are normally trailing or prostrate and branches which are naturally horizontal tend to become erect. This effect is sometimes observed in annual plants also, as in the case of *Euphorbia maculata* infected by *Uromyces euphorbiae*. Blackberry canes growing out from roots infected by *Gymnoconia*, besides having the characteristic growth described above, are free from thorns.

In spite of the intimate association of rust fungi with their hosts, very little apparent injury results to the

plants during the vegetative growth of the parasites. Deformations of various kinds are common in plants attacked by these fungi. Aside from those described above there is in many cases a marked stimulation to abnormal growth which results in the formation of galls, as the well-known cedar apples, or in enlarged and distorted flowers, fruits, and branches, or in the production of witches' brooms. The greater number of rusts, however, do not cause any abnormal deformation of their hosts, and the presence of the fungus is usually not evident until the time of spore-production, although it may be assumed, and is sometimes apparent, that the plants have been weakened or retarded in growth, particularly when the mycelium is widely dispersed in the tissue. At the time of spore-production, the injury to the host becomes unmistakable. The spores are produced in pustules beneath the epidermis. This is finally ruptured and the spores break forth forming the characteristic orange, brown, or black spots and patches to which these fungi owe their name. The injury is brought about both by the withdrawal of nutriment from the host cells and by the extensive destruction of the epidermis of the host and the resulting loss of water from the tissues beneath. The magnitude of the injury differs with the extent to which the plant is infected. Plants which are severely infected often lose their leaves, which wither and die prematurely. In annual or biennial plants this injury hastens the death of the plants, as in the hollyhock and the cereals, or, as in greenhouse carnations, impairs their vigor to such a degree that the plants are of little commercial value. In perennial plants like asparagus, the yearly injury of the assimilating parts results in the slow weakening of the roots through malnutrition and finally in the death of the plants. Apple trees are frequently defoliated as a result of infection by the cedar rust (*Gymnosporangium*). In plants grown for crops, whether flowers, fruits, or other parts are sought, these injuries diminish the yield, but in ornamentals the mere presence of the rust pustules over the surface greatly detracts from the appearance of the plants.

Specialization among rust fungi.

Rust fungi do not attack various plants indiscriminately. In general, each morphologically distinguishable species is confined to one or to a relatively small group of closely related host plants. Nevertheless, the degree of adaptation to particular hosts varies much with different species of fungi. Some species are truly plurivorous. A striking example of this habit is furnished by the hollyhock rust (*Puccinia malvacearum*) which inhabits about forty species belonging to many different genera of the subfamily Malvææ, and passes readily from one host to another. Many rusts which are apparently plurivorous have been found on closer investigation to be divisible into a number of so-called biological or physiological races, each of which is restricted to a comparatively small group of host plants. This type is illustrated by the common cereal rust (*Puccinia graminis*). This occurs on all the common cultivated cereals and on about 180 species of wild grasses. The forms on the different hosts are not morphologically distinguishable but culture experiments with this rust on the cereals and the common grasses have shown that it falls into a number of biological races each of which is more or less restricted to a small group of host plants, and cannot readily be transferred to plants outside of that group. Thus the form on oat infects also orchard grass and a few other grasses, but not wheat, barley, or rye; the form on rye infects also barley and some other grasses, but not wheat; and the form on wheat infects less readily barley, oat, rye, and some other grasses. This type of specialization is very common and occurs in many species which have a wide range of host plants. The separation into physiological races is not always sharp and clear-cut and often

a transfer of a race from one host to another can be accomplished by so-called bridging species of host plants, i. e., species which act as a common host to two races of rust. It appears also that the degree of specialization of different forms is not the same in different geographical regions. It is readily seen that the matter of specialization of rusts is one of considerable economic significance. In the case of truly plurivorous species of rusts, many wild plants may be the source of infection for cultivated plants. Thus the hollyhock is easily infected from *Malva rotundifolia* and other wild malows; but, in the case of species which, like the cereal rust, have become differentiated into a number of physiological races, there is comparatively little danger of infection from wild plants since the rust on each host has become more or less strictly adapted to its particular host. Thus, for example, different members of the pink family are inhabited by the carnation rust (*Uromyces caryophyllinus*) but each genus has its own physiological race which does not infect the members of other genera of the family. The specialization of rusts to particular hosts has also another economic bearing. When a given rust is restricted to one or more species of a genus but does not infect the others, these are said to be immune. Just as there are immune species, there may be immune varieties within a species, as the phrases "disease-resistant cowpeas," or "rust-resistant carnations," indicate. This fact, that the cultivated varieties of a given species show varying degrees of resistance, furnishes the basis for the breeding of immune varieties, which is one of the most promising means of overcoming the danger from attacks of rust.

Remedial measures.

Of the various groups of fungi, the rusts are the most difficult to combat. For most forms, especially those infecting cereals and other agricultural crops, no satisfactory methods of control have been developed since the usual methods of disease-prevention are either unprofitable or not applicable here. Even with horticultural crops, direct remedial measures have proved successful only in few cases, as with the apple rust, which can be successfully controlled by spraying with bordeaux mixture. Various mixtures, such as copper sulfate (one pound to fifteen gallons of water) and potassium sulfide (one ounce to one gallon), have been recommended and tried for carnation rust, but the growers are far from being in accord as to the effectiveness of these remedies. Environmental conditions have much to do with the prevalence of rust. Thus the severity of outbreaks of asparagus rust and probably of other rusts also is dependent on the amount of dew. In greenhouses it has also been found that the environment has much to do with the presence of rust on carnations and chrysanthemums, and that the maintenance of the best cultural conditions is one of the surest means of controlling rust on these plants. This method of control is, however, applicable in the field only in a restricted degree.

While the methods of direct control of rusts have not on the whole proved very successful, the indirect method by the breeding of resistant varieties seems to offer the most promising solution of the problem. Although the so-called rustproof varieties of plants have not generally proved to be entirely resistant, yet different degrees of resistance have long been noticed by growers, and varieties particularly susceptible to rust have been gradually eliminated. The history of the carnation rust in the United States probably furnishes an illustration of this process. Twenty years ago horticultural literature was replete with discussions of the carnation rust which caused much agitation among growers. At that time much was written of "rustproof" varieties, and mention is frequently made of varieties thrown out on account of rust. At the present time the rust once regarded as the "most dreaded of the carnation diseases" attracts but little attention, and within

the last few years has been scarcely mentioned in florists' journals. That a part of this result at least is due to the gradual elimination of susceptible varieties can scarcely be doubted, but the fact should not be overlooked that the seriousness of the early rust invasion may have been exaggerated, for even then conservative men felt impelled to warn against the agitated state of mind which caused growers to see rust in every discolored leaf. (McBride, *Am. Flo.* 8 p. 930, 1893; Herr, *ibid.* p. 980.)

Botanical features.

Botanically the rusts are of great interest because their life-cycle consists typically of two distinct generations. These are technically known as the gametophytic generation and the sporophytic generation, but for

3513. The cluster-cup stage of the wheat rust fungus growing on barberry leaf.

3514. Colonies of rust on the stem of wheat.

simplicity they may be designated respectively as the æcidial stage and the telial stage, terms derived from the names of the principal spore-producing structures which characterize the two phases. Each of these generations may produce one or more spore forms. The life-cycle of a rust is best understood by means of an example. One of the most familiar is the wheat rust.

If barberry bushes in the neighborhood of wheat-fields are examined in spring (May and June), there will usually be found on some of the leaves yellowish spots. Within the discolored area, on the under side of the leaf, there are a number of small cup-like openings with fringed margins. (Fig. 3513.) These are termed æcidia and from them yellow æcidiospores, which can be seen scattered like dust around the cups, are discharged. About the same time or a little earlier, flask-like pycnidia break through the epidermis on the upper side of the leaf. These discharge minute spore-like bodies whose function is not known. They do not infect either the wheat or the barberry. The æcidiospores are incapable of reinfesting the barberry. They can infect only the wheat and a few other grasses susceptible to this particular biologic race. On the wheat the germ-tubes of the æcidiospores penetrate the stomata of the leaf and stem and produce local colonies of mycelium which gives rise to uredospores (Fig. 3514). These are one-celled spores which are produced in many generations and which serve to propagate and spread the fungus during the summer. To them the rusty appearance of infected grain-fields is due. They can reinfest only wheat and the other graminaceous hosts of the fungus but not the barberry. Toward autumn the same mycelium which produces uredospores during the summer gives rise to teleutospores. These occur as black streaks and patches on the stems and leaves, upon which they remain during the winter. In spring the teleutospores germinate in place and produce short germ-tubes termed promycelia from which four minute sporidia are abjected. The sporidia are

borne away by the wind and when they alight on the barberry the æcidia are again produced. The sporidia do not reinfest grain.

Puccinia graminis represents the complete life-cycle of a rust of the most complex type. Rusts of this character, which alternate regularly between two hosts, are said to be heteroecious. Those which produce æcidiospores on the same host on which the other spore forms are borne, are said to be autoecious. Not all rusts have the entire complement of spore forms, one or more of which may be dropped from the cycle. Thus, neglecting the pycnosporangia which, so far as known, have no significance in the life of a rust fungus, the red cedar rust (*Gymnosporangium*) has æcidiospores on the apple and teleutospores on the red cedar; the hollyhock rust (*P. malvacearum*) has only teleutospores which germinate immediately or which may survive the winter and reinfest plants in spring; the blackberry rust (*Gymnoconia*) has only æcidiospores which germinate like teleutospores. Many rusts, like some of the grain rusts, are able to maintain themselves by means of uredospores which are capable of enduring the winter. This method of persistence through unfavorable seasons must be considered as a special and accidental adaptation to particular conditions, for it is not likely that any form of rust has become permanently reduced to the uredospore stage since this is merely a propagative spore-form of little morphological significance. Continuous uredospore production is likely to occur where plants are kept uninterruptedly in a growing condition like carnations in greenhouses, or fig trees and species of *Vitis* in tropical and subtropical regions. Under such conditions teleutospores are produced with comparative rarity.

Some common rusts.

The following are some of the common rusts on horticultural plants:

Uromyces caryophyllinus, the common carnation rust, occurs on several members of the pink family but is known in America chiefly in its uredo stage on the carnation upon which teleutospores also are sometimes found. Different physiological races occur on various members of the pink family, some of the European forms on tunicia and on saponaria have æcidia on *Euphorbia Gerardiana*, but in America the æcidial stage of the race on dianthus is not known. The presence of the fungus is indicated by the appearance of lead-colored pustules which appear first on the lower leaves and stems of the plants. The pustules soon rupture and discharge sooty powder made up of uredospores. These are blown or carried by spray to other plants. For germination of the spores a thin film of moisture such as that produced by dew is necessary. Avoidance of conditions which favor the germination of spores will tend to decrease the rust, but only such remedial measures as have been mentioned above can be suggested.

Uromyces appendiculatus, on bean, cowpea and related genera. Sometimes causes damage but not common. Æcidia and uredospores on the leaves, teleutospores mostly on the stems, on which they remain during the winter. The infected material should be destroyed.

Uromyces pisi produces its uredospores and teleutospores on the pea. The sporidia produced by the teleutospores infect the dormant buds of the subterranean shoots of *Euphorbia Cyparissias* in which the mycelium becomes perennial. From the infected rhizomes deformed shoots arise, on the leaves of which æcidia are borne.

Puccinia asparagi has all its spore-forms on *Asparagus officinalis*. This is the most serious parasite of the garden asparagus. It was first noticed as a menace in the eastern United States in 1896. It has since spread over the entire country. As a result of its ravages the system of asparagus-growing has been greatly modified in some regions while in other sections the commercial cultivation of asparagus has been practically abandoned. The palmetto varieties appear to be somewhat resistant to the disease. Sprays of sulfur-soda soap, and of bordeaux mixture, and dusting with sulfur in dry regions have proved more or less successful. Ornamental species grown in the United States are not affected by this rust.

Puccinia graminis, the black rust of cereals and grasses, while of great importance agriculturally is of interest to horticulturists only for the reason that the æcidial stage sometimes disfigures the leaves of *Berberis vulgaris* planted for ornamental purposes.

Puccinia malvacearum, the hollyhock rust, has only teleutospores which are produced in successive generations. The teleutospores produced during the summer germinate immediately and rapidly spread the rust. In regions where the winter is not too severe, those produced late in the season sometimes survive the winter, but in the northern states the fungus lives through the winter in the mycelial stage in the stems and petioles of *Malva rotundifolia*, on which developing sori can be found during the entire season. Destruction

of wild hosts and of diseased portions of plants is a partly successful method of control.

Puccinia chrysanthemi, the chrysanthemum rust, is known in the United States chiefly in the uredospore stage on chrysanthemums of which only some varieties appear to be susceptible. The rust rarely produces serious damage, and is readily controlled by the elimination of susceptible varieties.

Gymnosporangium juniperi-virginianæ, cedar rust, apple rust. The telial stage produces the galls known as cedar apples on the red cedar. After rains in spring the teleutospores ooze out from the galls in the form of horn-like gelatinous masses, an inch or more in length. They germinate in place and the sporidia infect the leaves and fruits of the apple on which the æcidial stage is produced. No appreciable damage is caused to the cedar, but apple trees are sometimes defoliated by this rust and the damage to orchards is often extensive where cedar trees are abundant. Removal of cedar trees prevents the occurrence of this rust on the apple. The fungus can be controlled also by spraying with bordeaux mixture.

Gymnosporangium globosum, another species much like the foregoing, is the common cause of apple rust in the East.

Cronartium ribicola has uredospores and teleutospores on various species of currants, but is chiefly of importance on account of the destructiveness of its æcidial stage to the white pine and other five-leaved pines. Introduced from Europe probably about 1906. Local in northeastern United States at present.

Coleosporium solidaginis occurs on aster, solidago, and other Compositæ. It is chiefly of interest because it also attacks the cultivated aster (*Callistephus hortensis*) causing considerable damage. The æcidial stage occurs on pines. The intervention of this stage is, however, not essential for the maintenance of the fungus since the uredo sori persist through the winter on the rosette leaves of solidago and other Compositæ.

Melampsora tremulæ is the common orange rust of poplars in the United States. Several races exist which have æcidia on larix, pine, and other plants. Numerous other species or subspecies of *Melampsora* occur on willows. The injury caused by these is not great.

Gymnoconia interstitialis, of the blackberry, has but one spore form, the æcidiospores which germinate like teleutospores. The rust is exceedingly common on the blackberry and raspberry covering the whole under surface of the leaves with blisters which burst and display the brilliant orange spore-powder. The mycelium is perennial and permeates the entire host. No satisfactory remedy has been suggested.

Uredo fici, an unattached uredo-form which is common on fig trees, causing a rusty brown appearance and premature falling of the leaves. Where figs are grown for fruit, considerable damage results to the crop from the loss of leaves. Common also in the tropics.

HEINRICH HASSELBRING.

RUTA (classical name of rue). *Rutacææ*. Perennial, glandular, punctate herbs, hardy or half-hardy North, quite hardy South but of no great horticultural value.

Plants often woody at the base, with terete branched sts.: lvs. alternate, simple, 3-foliate, pinnately cut or compound; fls. in leafy-bracted terminal corymbs or panicles, numerous, yellow or greenish; calyx short, persistent, 4-5-lobed or parted; petals 4-5, limb arched,

often dentate or ciliate; stamens 8-10; ovary sessile; caps. 4-5-lobed, the lobes indehiscent or dehiscent at the apex.—About 40 species mostly in the Medit. region and a few in W. and Cent. Asia.

graveolens, Linn. RUE. HERB OF GRACE. Fig. 3515. A hardy perennial, woody at the base, 1½-2 ft. high; lvs. fragrant, much divided; lobes oblong, the terminal obovate; fls. yellow. July.—Prop. by division and seeds. An old medicinal plant, with a very strong aromatic odor; sometimes spontaneous in this country.

Patavina, Linn. (*Haplophylum Patavium*, Hort.). A hardy perennial herb 4-6 in. high; lvs. glabrous, the lower oblong-spatulate, narrowed at the base, the others trisected and laciniate; corymb dense; pedicels somewhat longer than the fls.; fls. golden yellow. June, July.

F. W. BARCLAY.

F. TRACY HUBBARD.†

RUTABAGA: *Brassica*

S

SĀBAL (possibly a native name in South America, but the author of the genus does not explain). *Palmaeae*, tribe *Corypheae*. Spineless palms, low, tall, or almost stemless.

Trunk slender or robust, ringed or nearly smooth, creeping or erect, ascending at the base, clothed above with dead lf.-sheaths: lvs. terminal, orbicular or cuneate at the base, flabellately multifid; segms. linear, bifid, filamentous on the margins, induplicate in the bud; rachis short or long; ligule short, adnate to the rachis; petiole concave above, the margins smooth, acute; sheath short: spadices large, elongated, decompound, at first erect, the branches and branchlets slender, recurving, pendent; spathes sheathing the branches and peduncles tubular, oblique at the throat: bracts and bractlets minute: fls. small, glabrous, white or green: frs. small, globose, black, the short style basal.—Species probably 20, if Inodes is not separated. Fla. to Venezuela, and in Mex. Here belongs the palmetto or cabbage palm of the southern states. The best botanical account of the genus is Beccari's, *Le Palme Americane della tribu delle Corypheae*, pp. 10-83 (1907). Most of the species can be cult. in the temperate house, but any that may come into the trade from S. Amer. would require stove conditions. *S. Palmetto* can be grown outdoors from Charleston southward. *S. texana* and *S. exul* are handsomer species, and hardy in parts of Texas.

The arboreous species of *Sabal* have been separated by Cook (Bull. Torr. Bot. Club, 28:529) as Inodes. These species also differ in their foliage. "The leaves of *Sabal* are adapted for standing erect and avoid resistance to the wind by being split down the middle. The leaves of Inodes which are held horizontal from an erect axis have attained the unique adaptation of a

decurved midrib which braces the sloping sides of the leaf and effectively prevents the breaking above the ligule."

The cabbage palmetto (*S. Palmetto*) grows in groups of a few specimens to several hundreds or even thousands in the rich black soil on the banks of the St. Johns and Ocklawaha rivers of Florida, forming a glorious sight. They are found northward to South Carolina, but they attain their fullest development in Florida,

where they always form an important feature of the landscape. Generally they grow in dense groups, but they are more beautiful in all their parts where they have room enough to spread. In southern Florida underneath the crown of leaves is often found a dense wreath of ferns (*Polypodium aureum*), which heightens the charm of these palms considerably. On the St. Johns the trunk is often covered with the trumpet creeper (*Campsis radicans*), or it is hidden by the dense foliage of the cross-vine (*Bignonia capreolata*), both of which form a beautiful ornament, especially when in flower. These suggestions of nature are often followed by planters who have a feeling for nature-like landscape effects. The cabbage palmetto thrives even in the poor sandy soil, and it is greatly improved by cultivation. Even good-sized trees are not difficult to transplant if the whole stem is carefully dug out and all of

3516. *Sabal Palmetto*, the cabbage palmetto of the southern states.

the roots and leaves are cut off. If the stem has been set at least 3 feet deep and the soil is kept well watered after planting, the palmetto is almost sure to live. In addition to the palmetto, all of the *sabals* mentioned in this work are cultivated by the undersigned on high pine land in southern Florida. Under these conditions the *sabals* have proved a great success, as also all species of *Phoenix* and all *Cocos* of the *australis* type, while the species of *Washingtonia*, *Erythea*,

Livistona, and Trachycarpus have been an entire failure. *S. Blackburniana* is, in the judgment of some, the finest of all the fan-leaved palms that can be grown in Florida. All the species that form trunks are objects of great beauty when well grown. They need to be well fertilized, or the lower leaves will suffer and finally die, thus detracting much from the elegance of the specimen. They all grow naturally in rich black soil, but they all thrive exceedingly well in the sandy pine-woods soil if well fertilized and watered; in fact, they can hardly be fertilized too much, and the more nitrogenous manure and water they get the faster they grow. When transplanted they must be set deep. In planting palms make a hollow about 6 feet in diameter and about 2 feet deep in the center. This center, which receives the plant, is the deepest point, while the ground all around is slightly sloping. Care must be taken to remove the sand after heavy rains or the crown will soon be buried and the little plant dies. As the palm first forms the

of Mexico has been visited by collectors of seeds it would be remarkable if this attractive plant should not prove to be already in cultivation in European gardens."

BB. *Foliage green or essentially so, at least above.*

mauritiaeformis, Griseb. & Wendl.; also spelled *mauritiiformis*. Trunk middle-sized, but occasionally attaining 60-80 ft.: lvs. finally 12 ft. across; blade suborbicular, longer than the petiole, glaucous beneath, multifid to the middle, with loose fibers between the bifid lobes: spadix very long and much branched, appearing below the lvs.: fr. globose or inverted pear-shaped, about $1\frac{1}{2}$ in. long. W. Indies.—The name *mauritiaeformis* does not appear in the American trade, but *S. glaucescens*, Lodd. and Hort., probably belongs here, according to Grisebach. Nehrling writes: "*S. glaucescens* of the trade rivals *S. Blackburniana* in beauty and rapidity of growth. Its lvs., though smaller, have a beautiful bluish green color."

Palmétto, Lodd. (*Inòdes Palmétto*, Cook). CABBAGE PALMETTO. Fig. 3516. St. erect, 20-80 ft. high: lvs. 5-8 ft. long, cordate in outline, recurved at the summit, shorter than the petiole; segms. deeply cleft: spadix spreading, shorter than the lvs.: drupe black, $\frac{1}{8}$ - $\frac{1}{2}$ in. long. N. C. to Fla. and Bahamas. S.S. 10:507. A.F. 12:628.—*S. Mocinii*, Hort., is referred to *S. Palmétto* by Voss, but Nehrling describes it as a stemless plant from Mex., more beautiful than the dwarf palmétto, bearing immense lvs. on strong stalks, the lvs. attaining a height of 6-8 ft. Others think *S. Mocinii* is the same as *S. Blackburniana*. *S. Palmétto* has been confused in the European trade with *S. texana*. Very commonly planted as a shade and avenue tree in the southern states.

Blackburniana, Glazeb. (*S. umbraculifera*, Mart. *Inòdes Blackburniana*, Cook). St. 30-40 ft. high, thickened at the middle: blade ample, orbicular, glaucous, rather rigid, shorter than the petiole; lobes about 40, ensiform, bifid, filamentous, rather rigid: spadix more branched than in any other species: fr. inverted pear-shaped, about $1\frac{1}{2}$ in. long. W. Indies. G.F. 4:307. G.C. II. 2:777. Loudon's Gard. Mag. 5:52-7, with several figures. R.B. 35, p. 189.

causiàrum, Becc. (*Inòdes causiàrum*, Cook). PORTO RICO HAT-PALM. YARAY. Trunk to 40 or 50 ft. and 2 ft. thick, columnar or nearly so, light gray or nearly white: lf.-bases splitting into fibers and more or less remaining as long ribbons: lvs. about 12 ft. long, the blade and petiole about equal in length but both surpassed by the infl., the petiole keeled near the end above: fr. $\frac{1}{8}$ - $\frac{1}{2}$ in. diam., grayish, with a finely rugose or nearly smooth chestnut-brown seed.

texàna, Becc. (*S. mexicana*, Auth., not Mart. *Inòdes texàna*, Cook). Robust palm, to 50 ft. and $2\frac{1}{2}$ ft. diam. of trunk which is bright reddish brown: lvs. 5-7 ft. across, shining and yellowish green, the segms. often parted and filamentous, the petiole stout and equaling or exceeding the blade: terminal branchlets of infl. slender: seed about $\frac{1}{2}$ in. broad, with a prominent micropyle. S. Texas. S.S. 10:508.

exùl, Bailey (*Inòdes exùl*, Cook). A strong vigorous tree with large crown of vivid green lvs., and green trunk due to the color retained in the sheathing lf.-bases: lvs. otherwise much like those of *S. texana*: branchlets of infl. thickened: fr. solitary, with large seed not wrinkled above nor hollowed below.—Described from handsome trees planted at Victoria, Texas, probably native of Mex. Hardy and promising.

princeps, Hort. Large species with a stout trunk which is covered with the persistent bases of the old lvs.: lvs. very large, about 5 ft. long; blade divided into about 100 segms., chartaceous, green; segms. all

3517. *Sabal glabra*.

trunk in the soil and as the growth is rather rapid, this precaution is not necessary after the plant has attained a few feet in size. (H. Nehrling.)

A. *Trunk evident, usually tall.*

B. *Foliage very glaucous.*

uresàna, Trel. (*Inòdes uresàna*, Cook). Trunk 15-35 ft. high and upward of 1 ft. diam.: lvs. glabrous, very glaucous; petiole stout, concavo-convex, unarmed, about 40 in. long, nearly 1 in. wide and nearly $\frac{3}{4}$ in. thick; blade about 40 in. long and wide, multifid, with coarse straw-colored fibers from the sinuses, the center arcuately recurved: fr. of a single developed carpel, depressed globose, $\frac{3}{4}$ in. or less in diam., edible, green, or when dry dingy brown and somewhat glossy, the mesocarp then cottony; endocarp whitish straw-color, glossy within; seed polished, dark chestnut-brown, labyrinthiform-rugose, much depressed. Sonora, Mex., in the vicinity of Ures; intro. to cult. in S. Calif. R.H. 1910, p. 59. Described and figured in vol. 12 (1901) of Rept. Mo. Bot. Gard.—"From the two arboreal palmettos of the United States, *S. uresana* differs markedly in its pale, very glaucous foliage, and in the size of its fruit, which is of thrice the diameter of that of *S. Palmétto*, and usually a third larger than in *S. mexicana*, with the former of which species it agrees in having but one of the three carpels developed and fertile while in *S. mexicana* two or even all three are not infrequently developed. Considering the extent to which this section

rather shortly cleft at the apex, about 3 ft. long by $1\frac{1}{2}$ in. broad, acuminate, pointed: fruiting spadices pend-ent, about 6 ft. long, forming a very dense panicle: spathe tubular-funneliform, striate, obliquely truncate: fr. black, shining, globose. Habitat unknown; cult. in S. Calif.—Resembles *S. Blackburniana*.

AA. *Trunk none or creeping.*

glàbra, Sarg. (*S. Addisonii*, Guerns. *S. minus* or *minor*, Pers. *Corypha minor*, Jacq. not Linn.). DWARF PALMETTO. BLUE PALM. Fig. 3517. St. short, buried in the earth so that the palm appears stemless: lvs. 2-3 ft. long; blade circular in its outline, somewhat longer than the petiole, glaucous; segms. slightly cleft at the apex: spadix erect, much longer than the lvs., 3-6 ft.: drupe $\frac{1}{8}$ in. thick, black. Southern states. B.M. 1434.—Often cult. outdoors in the southern states. There are different forms, apparently unknown to the trade.

megacarpa, Small (*S. Etònia*, Swingle). SCRUB PALMETTO. Low shrub, the sts. elongated, creeping, and contorted: lvs. standing 4-5 ft. high, the sharp-edged petioles exceeding the nearly orbicular blades which are $1\frac{1}{2}$ -2 $\frac{1}{2}$ ft. across, deeply cleft at apex and segms., longer than body, filamentose: infl. 2-2 $\frac{1}{2}$ ft. long, ascending but becoming prostrate, branching; perianth yellowish white: fr. nearly globose, $\frac{1}{2}$ - $\frac{3}{4}$ in. diam. Fla.

The following are mostly trade names, but at present they can be only imperfectly described: *S. carulescens*, Bull. A native of Colombia intro. in 1875. Apparently only the juvenile state has been described. Lvs. elongate, linear-lanceolate, plicate, with a bluish or glaucous green color which is very strongly marked on the under surface. Nehrling writes that he cannot distinguish at present his specimens of *S. carulescens* from *S. glaucescens*.—*S. dealbata*, Hort. "This species," writes Nehrling, "reminds one of *S. Mociinii*, although it is smaller in all its parts. The lvs. are numerous, glaucous green and of a fine fan-shaped form. Compared with the sabals that form a trunk, these stemless species have little beauty, though they look well as foliage plants in company with *Cycas revoluta* and *Dioon edule*." The name "*dealbata*" means whitened, but it appears to be unrecognized in botanical literature in connection with Sabal.—*S. Giesbrechtii*, Hort., is *S. Palmetto*; at least so far as some gardens are concerned, but Beccari considers it an European name applied to cult. plants of *S. Palmetto*.—*S. glauca*, Hort. Pitcher & Manda, 1895, may possibly be meant for *S. glaucescens*.—*S. havanensis*, Lodd., according to Nehrling, "is a more upright grower than *S. Blackburniana*, has a slender st. and the lf.-stalks are longer and thinner. The lvs. have a bluish green color while young, changing to a fine dark green when they get older." Habitat unknown and the name has no botanical standing.—*S. Hoogendorpii*, Hort., is *Livistona Hoogendorpii*.—*S. javanica*, Hort., Pitcher & Manda, is possibly meant for *S. havanensis*, since Sabal is an American genus and is not known in Java.—*S. longijolia*, Hort., according to Nehrling "has very numerous, long and slender lvs. which are bright green above and silvery below."—*S. longipedunculata*, Hort., according to Nehrling, "is a stemless plant with smaller lvs. than those of *S. Mociinii* and very long and slender stalks." Reasoner adds that the lvs. are glaucous green. The last two are known only by these trade names, and are not certainly referable to any maintained species.

L. H. B.†

SABÀTIA (named after Liberatus Sabbati, an Italian botanist of the eighteenth century); also spelled *Sabatia*. *Gentianaceae*. Hardy annual or biennial (rarely perennial by stolons) herbs, making showy garden or border plants, although little grown.

Leaves opposite, sessile or clasping: fls. showy, rose-pink or -purple or white, in cymose panicles terminating the branches; calyx 5-12-parted, the lobes slender; corolla rotate, 5-12-parted, usually with a yellow eye: caps. globose or ovoid, 2-valved.—About 18 or 20 species, N. Amer. and Cuba, mostly on the coastal plain. Sabatias require a light sweet soil. Seed may be sown in fall or early spring. The plants are easily transplanted. Some of them grow in brackish places.

A. Fls. 5-parted, rarely 6-7-parted.

brachiata, Ell. St. slightly angled, 1-2 ft. high: lvs. linear to linear-oblong, obtuse, obscurely 3-nerved at the base: fls. showy, light rose to white, 1-1 $\frac{1}{2}$ in. across, in thyrsiform panicles, the lateral peduncles bearing usually 3-fld. cymes; calyx-lobes linear, shorter or nearly equaling corolla. Ind. to N. C. and south.

lanceolata, Torr. & Gray. St. simple, 1-3 ft. high: lvs. about 1 in. long, shorter than internodes, ovate-

lanceolate or ovate, acute, 3-5-nerved, the floral reduced to subulate bracts: fls. about 1 in. across, white, fading yellowish; calyx-lobe more than half length of corolla. May-Sept. Pine-barrens, N. J. to Fla.

angulàris, Pursh. St. somewhat 4-wing-angled, $1\frac{1}{2}$ -2 ft. high: lvs. ovate, 3-5-nerved: fls. fragrant, showy, light rose to white, 1-2 in. across, in much-branched pyramidal or somewhat corymbose cymes; calyx-lobes linear, much shorter than the corolla. Rich, light soil in open fields. W. Canada to Fla.

AA. Fls. 8-12-parted.

dodecandra, BSP. (*S. chloroides*, Pursh). Apparently perennial, usually in brackish marshes near the coast from Long Island southward: to 2 ft. high: lvs. oblong to oblong-lanceolate, blunt or somewhat acute: calyx-lobes herbaceous, 3-5-nerved; corolla rose-colored or white with yellow spot at base of each oblong-spatulate or oblanceolate segm. *S. Kennedyana*, Fern., is the New England representative, of fresh pond-shores, earlier-flowering: freely stoloniferous, to 2 $\frac{1}{2}$ ft.: basal lvs. oblanceolate-acuminate; st.-lvs. shorter, firm, lance-acuminate and subulate: calyx-lobes not herbaceous, linear-subulate; corolla-lobes cuneate-obovate, rounded or emarginate at summit, with much broader yellow spot.

L. H. B.†

SÀBIA (from its Bengal name, *Sabja-lat*). *Sabiaceae*. A genus of about 20 species of woody vines or sarmentose shrubs native to India, China, and Japan, with alternate petioled entire deciduous lvs. and axillary, solitary, or cymose, rather small and dull-colored, greenish, purplish, brownish, or yellow fls. followed by small blue drupe-like frs. Fls. perfect, 5-, rarely 4-merous; petals short, semi-orbicular to ovate; petals oval to oblong; stamens shorter than petals; ovary superior, 2-celled, each cell with 2 ovules: drupes usually reniform, blue, solitary or 2 and slightly cohering at the base, 1-seeded; stone reticulate.—Only the following recently intro. species is in cult., but little is yet known of its cultural requirements; at the Arnold Arboretum it is growing well under ordinary conditions and has proved hardy. Prop. is by seeds and probably by cuttings. *S. Schumanniana*, Diels. Climbing shrub, to 10 ft., glabrous: branchlets green: lvs. petioled, oblong-lanceolate, rarely elliptic, acuminate, broadly cuneate at the base, bright green, reticulate beneath, $\frac{1}{2}$ -4 in. long: fls. greenish to greenish-purple, cup-shaped, $\frac{1}{8}$ in. across, in slender-stalked, nodding, usually few-fld. cymes; peduncle filiform, 1-1 $\frac{1}{2}$ in. long: fr. reniform, $\frac{1}{4}$ in. broad; stone slightly compressed, reticulate. W. China.—The drooping blue frs., if freely produced under cult., apparently constitute the chief ornamental feature of this species.

ALFRED REHDER.

SACCHÀRUM (*saccharon*, old Greek name for sugar). *Gramineae*. The sugar-cane group, little grown for ornament, although making bold specimens.

Tall grasses with stout culm and ample panicles, the branches many-jointed: spikelets small, slender, 1-fld., surrounded by long silky hairs.—Species 12, in tropical regions, mostly of the Old World. Differs from *Erianthus* in having awnless spikelets. The most important species is the sugar-cane, which is extensively cult. in tropical and subtropical countries for the production of sugar. Prop. by cuttings of the st. Native country unknown, but probably E. Asia. Cult. from time immemorial by cuttings, for which reason many varieties have lost the power to flower or at least to produce fertile seed. Rum is produced from the fermented molasses.

officinàrum, Linn. SUGAR-CANE. St. 8-20 ft. high, 1-2 in. thick. Dept. Agric., Div. Agrost., Bull. 20:18 G.W. 8:261 (under the name *S. officinale*).—The different cult. varieties are distinguished by color and height of st.

spontaneum, Linn. Less tall and stout than sugar-cane, freely blooming, found in the Medit. region, where it is sometimes cult. as a hedge-plant, and throughout the tropics of the Old World. A variety of this, *S. ægypticum*, is shown in Gn. 11, p.78; 16, p. 323.

ciliare, Anders. Lvs. very narrow, channeled, glaucous, the lower erect. Intro. from India.—Said to make large clumps and to be hardy at Santa Barbara, Calif., but not known to bloom there. A. S. HITCHCOCK.

SACCOLABIUM (name refers to the saccate labellum). *Orchidaceæ*. Epiphytic herbs with erect leafy stems increasing in length by continued growth at the apex, grown in warm glasshouses.

Leaves distichous, leathery and fleshy, usually channeled: infl. lateral, in the cultivated species a long, densely fld. cylindrical raceme; fls. medium or small; sepals subequal, free, spreading, the lateral pair not decurrent on the base of the column; petals similar, sometimes wider; labellum united with the base of the column, spurred, the mouth of the spur open; pollinia on a filiform stipe.—About 20 or more species. Can be prop. by offsets and by cut-backs. Fresh stock is constantly imported.

This interesting genus embraces a number of pretty and distinct species from Borneo, Cochin-China, India, Java, and Philippines. They are closely allied to the genera *Aërides*, *Phalænopsis* and *Vanda*, and require somewhat similar treatment, but do not always acclimatize themselves as readily to artificial cultivation unless given a location with more or less natural surroundings, although some of the more free-growing species, like *S. ampullaceum*, *S. curvifolium*, *S. caeleste*, and *S. Hendersonianum*, can usually be grown successfully in the cattleya or cypripedium department. The large-growing species with thick succulent leaves require a warm moist atmosphere where the winter temperature can be retained at 65° to 70° F. by night and about 75° during the day, and in the summer or growing season 10° in advance of this. All succeed best when suspended from the roof in pans, baskets or on blocks where they can have free circulation of air about them at all times, receive indirect benefit of the sun's influence, which will harden their tissue, and where the compost may readily and frequently dry out, during the resting period especially. Grown otherwise the more succulent species, such as *S. giganteum* (a *Vanda*), make soft weak tissue, which is susceptible to wet-spot, a usually fatal disease. Clean chopped sphagnum, freely interspersed with broken pieces of charcoal, is the most satisfactory growing material, and this should not be pressed in so firmly as entirely to exclude access of air to the roots, but the plants must always be firmly secured with pieces of charcoal, potsherds or other similar material, or securely fastened with copper wire to keep them in position, otherwise being more or less top-heavy they are liable to work loose, under which conditions they cannot become properly established. Shading should be applied to the glass from February until November to break the sun's direct rays, but during the remainder of the year when the solar light is weak its direct influence will be found beneficial. In bright weather in the growing season the plants need a liberal supply of water, both at the roots and over the foliage, but during the resting period and in wet inclement weather, water and syringing must be carefully and sparingly administered. Judgment in this respect is very essential to the successful culture of these plants. The supply of saccolabiums is kept up by fresh importation. These cultural directions apply also to the genus *Rhynchostylis*. (Robert M. Grey.)

AA. Fls. rose-colored.

Hendersonianum, Reichb. f. Dwarf: lvs. 4-6 in. long, strap-shaped, subacute, distichous on the sts. but spreading in various directions: raceme upright,

about as long as the lvs.; fls. forming a cylindrical mass, bright rose, $\frac{2}{3}$ in. across; dorsal sepals orbicular, concave, lateral ones larger, obovate-oblong; petals obovate; labellum a blunt, straight spur with 3 teeth at the mouth, white. Borneo. B.M. 6222.

ampullaceum, Lindl. Fig. 3518. Dwarf: st. 6-8 in. high, with 2 rows of lvs.: lvs. strap-shaped, channeled, apex truncate and dentate: racemes nearly erect, 4-6 in. high; fls. deep rose-color; sepals and petals ovate, veined, spreading out flat; labellum linear-falcate, one-half as long as the petals; spur slender, straight. May, June. N. India. B.M. 5595. P.M. 13:49. J.H. III. 32:463. Var. *moulmeinense*, Hort., is a geographical variety with stronger growth and larger fls.

AA. Fls. orange or scarlet-orange.

curvifolium, Lindl. Sts. short: lvs. linear, 8-10 in. long, 2-toothed at the apex: racemes somewhat drooping, 6 in. long, dense; fls. 1 in. across, bright orange-scarlet; sepals and petals ovate to obovate, spreading;

3518. *Saccolabium ampullaceum*. ($\times \frac{1}{2}$)

labellum orange, blade linear, truncate, spur obtuse. May, June. Burma, Java. B.M. 5326 (as *S. miniatum*). I.H. 13:493.

cèrinum, Reichb. f. St. short, thick: lvs. strap-shaped, obtusely 2-lobed: raceme dense, half drooping; fls. orange, with a paler spur; sepals oblong; petals ovate. Sunda Isls.

AAA. Fls. white, spotted with blue.

caeleste, Reichb. f. Plant rarely 1 ft. high, with decurved lvs. and erect, densely fld. racemes 6-9 in. long: fls. white, with the front of the lip and the tips of the segments sky-blue; sepals and petals cuneate, oblong, obtuse; labellum rhomboid, spur compressed, curved. July, Aug. Siam. J.H. III. 28:87; 46:25.

S. bellinum, Reichb. f. Sts. short; lvs. 7-12 in. long.; fls. fleshy, $1\frac{1}{4}$ in. across; sepals and petals spreading, somewhat incurved, similar, obovate-oblong, yellow, blackish-purple-blotched; lip sub-globose saccate and with a lunate blade, the former white, purple-spotted, the blade 2-lobed, pubescent above, fimbriate-denticulate, white, with the disk orange-yellow, purple-spotted. Burma. G.C. III. 39:419. J.H. III. 48:423.—*S. Blumei*, Lindl.=*Rhynchostylis retusa*.—*S. dasypogon*, Lindl. Allied to *S. bellinum*. Sepals and petals yellow; lip white with purple markings. Nepal.—*S. fragrans*, Par. & Reichb. f. Fls. numerous, white, violet-scented; lip mauve-purple. Burma.—*S. Fürstenbergianum*, Schlecht. Infl. branched; fls. rose-red with paler spur and white column. Siam. O. 1912:68.—*S. giganteum*, Lindl.=*Vanda densiflora*.—*S. glomeratum*, Rolfe. Sts. trailing, often 1-3 ft. long; racemes densely many-fld.; fls. small, yellow, spotted and striped with brownish red. Borneo. G.C. III. 54:317.—*S. gracie*, Lindl. "A very elegant little species, with slender growths and long decurved racemes of many small white fls." Ceylon.—*S. guttatum*, Lindl.=*Rhynchostylis retusa*.—*S. Harrisonianum*, Hook.=*Rhynchostylis violacea* var. *Harrisonianum*.—*S. illustre*, Hort., probably=*Vanda densiflora* var. *illustre*.—*S. penan-gianum*, Hook. f. A small plant, only a few inches high; fls. with light yellow sepals; side lobes of lip and wings of column narrowly margined with purple. Malay Penins.—*P. platycalcaratum*, Rolfe. Dwarf herb; fls. very small, with sepals and petals yellow, spotted with brown. Burma.—*S. præmorsum*, Lindl.=*Rhynchostylis retusa*.—*S. Regnierii*, Hort. Plant small; fls. in short racemes, orange-colored.—*S. retusum*, Voight=*Rhynchostylis retusa*.—*S. Rheedi*, Wight=*Rhynchostylis retusa*.—*S. rubescens*, Rolfe. Sts. a foot tall; lvs. oblong, 5-6 in. long, 1-1 $\frac{1}{4}$ in. broad; racemes 3-5 in. long, many-fld.; fls. $\frac{1}{4}$ in. long, light rosy purple; dorsal sepal elliptic, obtuse, $\frac{1}{2}$ in. long, lateral sepals ovate; petals elliptic, obtuse, $\frac{1}{2}$ in. long; lip 3-lobed. Annam. B.M. 8121.—*S. sarcochiloides*, Schlecht. Racemes spreading, short; fls. small, lasting only a day, white; sepals and petals with violet-red spots on base; lip with orange-yellow side lobes. Philippines.—*S. violaceum*, Reichb. f.=*Rhynchostylis violacea*.

GEORGE V. NASH.†

SACCOLOMA (from Greek for *sac* and *edge*, referring to the indusia). *Polypodiaceæ*. A group of tropical ferns, somewhat related to *Davallia*. They are pinnately divided, often of large size, and with scaly petioles; petioles and pinnæ not jointed to their points of attachment: indusia attached along one side at the base.

inaequale, Mett. (*Davallia brasiliensis*, Hook.). A large stove fern with creeping rootstock: lvs. as much as 6 ft. long, twice-pinnate or more. Common in the American tropics.

R. C. BENEDICT.

SADLERIA (named after Joseph Sadler). *Polypodiaceæ*. Arborescent ferns suitable only for the warm-house: about 3-4 $\frac{1}{2}$ ft. tall; lvs. large, tufted, double-pinnate, all similar: sori continuous, close to the midrib on each side: receptacle elevated; the involucre narrow, of the form of sorus, leathery, at first wrapped over the sorus, later spreading.—About 5 species, Hawaiian Isl. *S. cyathoides*, Kaulf. About 3-4 ft. high: the stipe strong, erect, 6-18 in. long, naked except at the base and there clothed with long-linear scales: fronds 4-6 ft. long, 9-18 in. broad; pinnæ 8-12 in. long, $\frac{1}{2}$ - $\frac{3}{4}$ in. broad, cut down to the rachis into very many, connected, linear pinnules, $\frac{3}{8}$ - $\frac{1}{2}$ in. long, acute or bluntish. Hawaii. G.C. II. 7:761. G.Z. 22, p. 122.

SAGE (*Salvia officinalis*). A sweet-herb, used for seasoning, and somewhat in domestic medicine.

For at least three centuries this shrubby fibrous-rooted perennial from southern Europe has been widely cultivated in kitchen-gardens for its aromatic whitish green wrinkled oval leaves. These are arranged oppositely on ascending or decumbent branching stems which seldom exceed 18 inches in height. In early summer the upper parts of these bear generally blue, though sometimes pink or white flowers, followed by almost black spheroidal seeds borne in the open cups. The name *Salvia* is derived from *salvo*, to save, in reference to the plant's use in domestic medicine; the name sage, from its supposed power to make people wise by strengthening the memory. In modern medicine it is but little used. In domestic practice, however, it is credited with tonic, sudorific, carminative, anthelmintic, and stomachic properties, and is frequently used as a gargle for apthous affections of the mouth and pharynx. Its pleasant, though powerful-smelling, bitterish leaves are used for flavoring sausages and some kinds of cheese,

for seasoning soups and stews, but mainly for dressings with luscious strong meats such as pork, goose, and duck. Among culinary herbs it ranks first in America, being more widely cultivated than any other except parsley, which is more largely employed for garnishing than as a flavoring agent. When possible the young leaves should be used fresh, for unless carefully dried they lose much of their aroma, which is due to a volatile oil and which even with careful curing rapidly dissipates. For best results the shoots should be gathered before flower-stems develop, because they are then richer and because later cuttings may be made. For drying upon a commercial scale, since this plan is thought to involve too much labor, the plants are cut in August if seed has been sown early, and the stumps, if not too short, produce again in late autumn; or if grown as a secondary crop, which is the common way, they are cut only once—namely, in autumn. Plants grown from cuttings (see below) will often produce three crops in a season. Upon a small scale, a warm airy room is best for drying, the plants being either laid loosely upon racks or the floor, or hung from the ceiling and walls. Upon a larger scale, a fruit-evaporator with a steady current of warm air at about 100° F. may be used. After drying, the leaves are rubbed to a powder and stored in air-tight vessels.

Sage does best in an open sunny aspect and a well-drained mellow loam of medium texture, rich in humus and nitrogenous matter. Stable-manure or a fertilizer containing potash, phosphoric acid, and nitrogen should be applied before the plowing, if done in the spring. Fall plowing is generally preferred when sage alone is to occupy the land. In each case plowing should be as deep as the surface soil will profitably permit. Thorough fining of the soil must precede, and clean cultivation follow planting, the plants being set in drills about 15 inches apart and 10 inches asunder for manual cultivation, or 18 to 21 inches apart and 10 inches asunder for power cultivation. The former method is, as a rule, more profitable though more laborious. After harvesting (see above) if the bed is to be permanent, northern plantations should be mulched with marsh-hay or other material free from weed seeds. For garden practice it is common to divide the clumps biennially, since the plants become straggling if left longer. Upon a commercial scale, however, it is better to rely upon cuttings or seedlings.

Propagation may be by seed, cuttings, layers, or division. Seed, the vitality of which lasts three years, may be drilled thinly in flats in greenhouse, hotbed, or coldframe in early spring; or out-of-doors as soon as the ground becomes dry enough, in specially prepared beds of fine soil, covering them about $\frac{1}{2}$ inch deep. In the former case the plants must be pricked out and hardened off to render them stocky and hardy before transplanting; in the latter, they are taken directly to the field. This operation may be performed from mid-June until late July, the plants being not less than 2 to 3 inches tall. The former method, which is considered the better, is the common commercial practice. Cuttings may be of mature or of immature wood. With each, shade and moisture are essential to success. Mature wood cuttings, made in early spring, should be ready for the field in less than six weeks; immature, taken from outside shoots just before they would form blossom-heads, are left in the cutting-bed until the following year. Such plants are usually more prolific than those grown from mature wood or from spring seedlings, and are, therefore, best when sage alone is to occupy the land. But when it is to follow some early vegetable, mature wood cuttings or seedling plants will probably be found best, though little or nothing can be cut before September. As practised by market-gardeners in the vicinity of New York, each of the above methods has its advocates, but practically all agree upon the plowing and harrowing of the ground in June or

July after harvesting an early crop, such as beets, cabbage or peas. About twice in the three weeks after setting the plants, the field is raked to destroy sprouting weeds and to keep the surface loose, after which, if well done, but slight hoeing is necessary. In September, when the plants crowd each other, each alternate plant or row of plants is cut for sale and the remainder allowed to fill the space. At the first cutting each plant should make about two marketable bunches; at the second at least three. This practice not only insures plants full of leaves at each cutting but at least doubles the quantity in the end.

In America the green broad-leaved varieties are in far greater demand than the colored and the narrow-leaved kinds. The best variety known to the writer is Holt Mammoth, which is exceptionally prolific of large leaves. It is said to produce no seed. M. G. KAINS.

SAGËNIA. A generic name for a group of tropical ferns here referred to *Tectaria*, from which there is no valid distinction. For *S. decurrens* see *Tectaria decurrens*.

SAGERËTIA (after Augustin Sageret, French botanist, 1763-1851). *Rhamnaceæ*. A genus of about 15 species of armed or unarmed often scandent shrubs native to the warmer parts of Asia, in Amer. from N. C. to Mex., with opposite or nearly opposite, entire or serrulate, small, deciduous or persistent lvs. and with minute whitish fls. in terminal or axillary spikes or panicles, followed by small berry-like, mostly purple frs. Fls. perfect, 5-merous; the hooded petals and the stamens not exceeding the sepals; disk cup-shaped, 5-lobed; ovary superior, 2-3-celled with a short 2-3-lobed style; fr. a small globose drupe with 2-3 leathery nutlets.—These plants are little known in cult. *S. theezans* has been recently intro. by the Dept. of Agric.; according to F. N. Meyer it may be useful as a hedge-plant and its fls. have a delightful fragrance which attracts numerous insects; it is apparently not hardy N., while *S. pycnophylla* has proved hardy at the Arnold Arboretum. The American *S. minutiflora* is not recorded as being in cult., but may possibly have been planted in collections in the southern states. The frs. of some species are sweet and edible. Prop. is by seeds and probably by cuttings like berchemia which it resembles in habit and general appearance. *S. theezans*, Brongn. Spinescent shrub, to 6 ft., with slender spreading branches: lvs. persistent, or subsistent, short-petioled, ovate or oval, obtusish, subcordate or rounded at the base, minutely serrulate, lustrous above, glabrous or at first slightly villous beneath, $\frac{1}{8}$ –1 in. long; fls. sessile in villous spikes $\frac{1}{2}$ –1 in. long or sometimes longer and forming terminal panicles leafy at the base; sepals slightly pubescent outside: fr. purplish black, about $\frac{1}{2}$ in. across. Fls. in autumn; fr. in spring. China. *S. pycnophylla*, Schneid. Similar to the preceding species: lvs. smaller, $\frac{1}{8}$ – $\frac{1}{2}$ in. long, rarely nearly $\frac{3}{4}$ in. long, sometimes acutish: fls. white, glabrous, in slender glabrous spikes $\frac{1}{2}$ –1½ in. long, usually only 1–4 at the ends of the branchlets. W. China. *S. minutiflora*, Trel. (*S. Michauxii*, Brongn.). Spinescent, straggling or trailing shrub: lvs. short-petioled, leathery, ovate to ovate-oblong, acute, serrulate, pubescent while young, glabrous and lustrous at maturity, $\frac{1}{2}$ –1½ in. long; fls. $\frac{1}{10}$ in. across, in terminal and axillary slender sometimes paniced spikes: fr. $\frac{1}{2}$ in. across, often gibbous, purple. Fls. in autumn; fr. in spring. N. C. to Fla. and Ala.

ALFRED REHDER.

SAGÏNA (Latin, *fatness*; perhaps alluding to the forage value). *Caryophyllaceæ*. PEARLWORT. Annual or perennial tufted herbs, sometimes used for edging.

Leaves awl-shaped: fls. small, usually comparatively long-stemmed; sepals 4–5; petals 4–5, entire or slightly emarginate, minute or none; stamens equal in

number to the sepals or twice as many; ovary 1-loculed, many-seeded; styles of the same number as the sepals and alternate with them.—About 50 species, natives of the temperate and colder regions of the world.

subulata, Wimm. (*S. pilifera*, Hort. *Spérghula pilifera*, Hort. *Spérghula subulata*, Sw.). PEARLWORT. An evergreen, hardy, densely tufted little plant, covering the ground like a sheet of moss: lvs. very small, stiff, aristate on the margin, linear: sts. branching and creeping: fls. white, studded all over the plant on long, very slender peduncles. July–Sept. Corsica. R.H. 1896, p. 435. R.B. 20:153. Var. *aurea* has lvs. marked with yellow. A good rock-plant in shady places. Cult. similar to *arenaria*. Prop. by division.

F. W. BARCLAY.

SAGITTÀRIA (*sagitta* is Latin for arrow, referring to the arrow-shaped leaves). *Alismaceæ*. ARROWHEAD. Perennial hardy herbs useful for foliage effects in bogs and shallow ponds and also for their white buttercup-like flowers.

Plants of mostly erect habit, aquatic, the lvs. and scapes arising from more or less tuberous or knotted rootstocks: lvs. typically arrow-shaped, with long basal lobes, but sometimes long and linear: fls. imperfect, monœcious (staminate fls. usually in the uppermost whorls) or dicecious, with 3 white broad petals and 3 small greenish sepals, the stamens and pistils numerous, the latter ripening into small achenes; infl. composed of successive whorls of 3 stalked fls. Sometimes the lvs. are floating. The number of species admitted is variable, but Buchenau in the last treatment of the genus in Engler's *Das Pflanzenreich*, hft. 16 (iv. 15,

1903) describes 31. Temperate and tropical regions of the world though lacking in Afr. and Austral.

Sagittarias are mostly used for colonizing in the open, but *S. montevidensis*—now the most popular species—is grown in indoor aquaria or plunged in open ponds in the summer. The arrowheads are perennials of easy culture, although likely to be infested with aphids. Propagation is by division, or sometimes by seeds.

A. *Sepals of pistillate fls. (usually in the lower whorls) erect after flowering, and the pedicels of these fls. thick: carpels not glandular.*

montevidensis, Cham. & Schlecht. GIANT ARROWHEAD. Very large, sometimes growing 6 ft. tall, with lf.-blades 1–2 ft. long: lvs. arrow-shaped, with long, diverging, sharp basal lobes: fls. very large (2 to nearly 3 in. across), the rounded petals white with a purple blotch at the base. Argentina to Brazil, Chile, and Peru. B.M. 6755. Gn. 27:8. G. 17:273. G.W. 4, p. 68. G.Z. 30:241. I.H. 31:543.—First known as a cult. plant from seeds sent to England in 1883 from Buenos Ayres by John Ball. It is now a popular plant for aquaria

and lily-ponds. Tender to frost. It is sparingly naturalized in the southern parts of the U. S., on both the Atlantic and Pacific sides.

AA. *Sepals of pistillate fls. reflexed after flowering: pedicels of these fls. slender: carpels somewhat glandular.*

B. *Bracts at base of whorls united, as if only 1.*

subulata, Buch. (*S. natans*, in part. *S. pusilla*, Nutt.). Slender and simple, usually only a few inches high: lvs. linear or narrowly oblanceolate, rigid: fls. few, usually in 1 whorl, white, $\frac{1}{2}$ – $\frac{3}{4}$ in. across, the filaments broad. N. Y. to Ala., along the coast.—Offered by dealers in native plants. A plant once sold as *S. natans* is said to have come from the Amazon Valley; from this the form known as "New Era" was derived; and a cross of the latter with "*S. lanceolata*" (*S. lancifolia*?), native in La., gave the form "Francis M." *S. natans*, Pallas, the accepted species under this name, is native in N. Eu. and Siberia.

BB. *Bracts 3, at base of the whorls.*

C. *Lvs. usually distinctly sagittate.*

latifolia, Willd. (*S. variabilis*, Engelm.). Fig. 3519. Very variable in stature and shape of lvs., ranging from a few inches to 3–4 ft. tall: lvs. mostly broad-sagittate with long basal lobes, but running into very narrow forms: fls. clear white, about 1 in. across, usually monœcious, the filaments slender: achene winged, with a lateral or oblique beak. Common everywhere in margins of ponds and lakes, and offered by dealers in native plants for colonizing in bog-gardens and in lily-ponds. There is a double-fl. form known as *S. variabilis fl.-pl.*, Hort., which probably belongs here. G. 29:31.

sagittifolia, Linn. OLD-WORLD ARROWHEAD. Rhizome thick and tuberous, stolon-bearing: lvs. broad and sagittate, very variable in form and size: scapes erect, simple or branched, overtopping the lvs.: bracts narrow-ovate, free or slightly connate at base, shorter than the pedicels: petals large, white; filaments glabrous: achene nearly or quite orbicular and in this respect differing from the allied American species. Throughout Eu. and Asia.—By some authors the American *S. latifolia* and others are considered to be con-specific. Var. *fiore-pleno*, Hort. (*S. japonica*, Hort. *S. japonica fl.-pl.*, Hort.), is a form with double fls. common in cult. G.C. III. 30:171. Gn. 74, p. 67. G.M. 44:779. G.W. 3, p. 621. J.H. III. 43:219.—*S. chinensis* of most trade-lists is apparently one of the many forms of this species. There appears to be another *S. chinensis* in the trade, with lanceolate lvs., the botanical position of which is undetermined.

CC. *Lvs. usually oblong or linear and not sagittate.*

D. *Filaments slender, tapering upward, cobwebby.*

lancifolia, Linn. Erect and somewhat rigid, glabrous, the scape sometimes reaching 5 ft.: lvs. lanceolate to narrow-oblong to nearly linear, nerved from the thick midrib: fls. white, in several whorls. Swamps, Del. to the tropics.

DD. *Filaments abruptly broadened, pubescent.*

graminea, Michx. Erect and simple, glabrous, 2 ft. or less high: lvs. reduced to phyllodia, flat, broad-linear to lance-elliptic, pointed: fls. small, white, in 2 or 3 whorls. Newfoundland to Gulf.

S. macrophylla has appeared in trade-lists as "a variety with large foliage and tall lax spikes of white fls." Its botanical position is uncertain as there are two distinct things of this name, one a valid species, the other a large-lvd. form of *S. sagittifolia*.

F. TRACY HUBBARD.†

SAGUËRUS (East Indian name). *Palmaceæ*. An older name for *Arenca*, but discarded by the "nomina rejicienda" of the Vienna rules. *Arénga mindorénsis*, Becc. (*Saguërus mindorénsis*, O. F. Cook), has recently

been intro. by the U. S. Dept. Agric. from the Philippines. It is described as a palm 5–10 ft. high, and probably of decided ornamental value for greenhouses and probably also in S. Calif. and S. Fla. Yet little known in this country.

SÂGUS RÚFFIA: *Raphia*.

ST. JOHN'S-WORT: *Hypericum*.

SAINTPAULIA (from the discoverer of the plant, Baron Walter von Saint Paul). *Gesneriææ*. Hairy often stemless perennial herbs, used for greenhouse flowering, the blossoms providing an attractive blue.

3520. *Saintpaulia ionantha*.—A young plant just coming into bloom. ($\times \frac{1}{2}$)

Leaves long-petioled, ovate: peduncles radical (or axillary in the caulescent species), 1–5 in. high, bearing several (or 1) fls. in a loose cyme: calyx small, deeply 5-lobed; corolla wide-campanulate, tube short, the lobes elliptic, blue; perfect stamens 2; ovary hairy: caps. oblong, loculicidally 2-valved; seeds small, ellipsoid.—Four species, Trop. Afr.

The end of March is a good time to propagate saint-paulias, when the ripened leaves should be cut off with about an inch of the stalk attached, and inserted in the sand-bed, covering only a small part of the leaf-blade. The sand should not be kept too wet during the process of rooting. Their propagation from seed and general culture is similar to that of gloxinia. The plants may be flowered the entire year or given a period of rest by partly withholding water. (G. W. Oliver.)

ionantha, Wendl. AFRICAN VIOLET. USAMBARA VIOLET. Fig. 3520. Stemless, hairy: lvs. many, $1\frac{1}{2}$ in. long, ovate or subcordate, thin, regularly crenate, clad on both surfaces with many short and a few very long white hairs: peduncles 1–4 in. long, 1–6-fl. calyx-lobes linear; corolla-lobes not very equal: caps. narrow-oblong. Trop. Afr. Gt. 42:1391 and p. 323. Gn. 47:133; 74, p. 103; 79, p. 13. G.M. 37:62; 55:97. G.C. III. 13:685. Gn.W. 25:345. G.W. 10, p. 343. R.H. 1893, p. 321. Var. *grandiflora*, Hort., has much larger fls. than the type, the fls. intense violet. Var. *variegata*, Hort., has the lvs. variegated with light yellow turning to white.

kewénsis, C. B. Clarke. Lvs. entire, with numerous long white hairs: calyx-lobes oblong-linear: caps. 2 or 3 times as broad as the preceding and more shaggy, white-hairy. Trop. Afr. B.M. 7408. R.B. 20:109 (both as *S. ionantha*).—Very closely related to *S. ionantha* and confused with it.

S. pusilla, Engler, and *S. Goetzedana*, Engler, of German East Africa, appear not to be in cult.

F. TRACY HUBBARD.

SALAD PLANTS are those with soft and edible leaves or stems, or both, that may be used raw or in the preparation of uncooked dishes.

The principal salad plant in America is lettuce, which is used exclusively, but not always expertly, for salads. For full directions for growing lettuce in the garden and under glass, see *Lettuce* and *Forcing*. Next to lettuce the best-known salad plant in this country

3521. Staminate catkin of *Salix discolor*. (Natural size.)

3522. Pistillate catkin of *Salix discolor*. (Natural size.)

is probably endive, which is excellent, especially when well-blanching plants are to be had in the winter. Chicory is much like endive, as regards its treatment either in the garden or in the salad-dish. Like endive, it is frequently seen in the larger city markets. The common dandelion should be mentioned in this category. When forced and blanched it makes a salad fit for the most cultivated epicure. For ordinary home cultivation and use, however, the common garden cress (*Lepidium sativum*, not water-cress, nor upland cress) ranks next to lettuce in value. Its rapid growth and high flavor equally recommend it. This plant is said to be a great favorite in English gardens and forcing-houses, where it is grown in mixture with white mustard and is pulled very young and eaten roots and all. Corn salad is another plant sometimes grown in gardens and used for salad-making. It is most acceptable to those who do not relish the pungency of mustard and cress. Chives is used by many persons as an ingredient of lettuce and other salads; also young onions. Many other plants are used in various places and by various persons for salads.

Besides the salad plants proper, many vegetables are used in a cooked or raw condition for salads. Such are cabbage, cauliflower, brussels sprouts, potatoes, lima beans, beets, Jerusalem artichoke, and the like. With salad plants may also be included pot-herbs, or "greens." The plants especially to be mentioned in this category are swiss chard, beet-tops, spinach, kale, endive, wit-loof and mustard. Many other plants find occasional or local favor. See *Greens*.

The only general cultural directions which can be given for salad plants are that blanching is often desirable and a quick unchecked growth is always a requisite. An abundance of rapidly available fertilizer and plenty of water are therefore to be insisted on. A warm light soil, in the best mechanical condition, is necessary for the same reasons.

F. A. WAUGH.

SALICORNIA (Latin, *sali* and *horn*; saline plants with horn-like branches). *Chenopodiaceæ*. GLASSWORT. MARSH SAMPHIRE. A group of about 12 widely scattered species of leafless seashore herbs, hardy or tender, annual or perennial. This and other chenopods which grow in large quantities in the Medit. region were formerly used in making soap and glass, as they yield a large percentage of soda. The ashes of such plants were known to the trade as barilla. The species have probably never been regularly in cult. and have no horticultural interest.

SALISBÜRIA: *Ginkgo*.

SALIX (ancient Latin name of willow). *Salicaceæ*. **WILLOW.** Dioecious trees and shrubs, planted for the foliage and interesting habit, for shade, screens, and cover; flowers in catkins, mostly in spring and in many species very early.

Erect, or some arctic and alpine species prostrate, glabrous, pubescent or tomentose: lvs. simple, alternate, mostly elongated and pointed, the stipules persistent and prominent or caducous: buds with a single bud-scale: fls. in lax scaly spikes (aments or catkins), each fl. subtended by a single entire scale and nearly or quite destitute of perianth; the staminate fl. with 1, 2, or 3-6 stamens; the pistillate fl. of a single pistil composed of 2 carpels and 2 more or less divided stigmas; at maturity the pistil dehisces, setting free the small appendaged seeds.—Species and species-like hybrids probably 300, widely spread in the northern hemisphere and a few in the southern hemisphere; no native species are reported in New Zeal. and Austral. In temperate regions, they are mostly plants of water-courses, shores, and swamps; but a good number run into the far N. and the high elevations where conditions of moisture are maintained. The wood is light, soft, and porous. For the staminate and pistillate fls of willow, see Fig. 1523, Vol. III. The catkins or "pussies" are also shown in Figs. 3521 and 3522 herewith. In rare cases, a willow may be monoecious.

Many hybrids have been described based on specimens found in nature that presented characters intermediate between recognized species. Artificial hybrids have also been made between many species. The dioecious habit of the species seems to facilitate cross-pollination, and it is probable that the intermediate forms so frequently met with and designated in the monographs as varieties are natural hybrids. Upward of one hundred hybrid willows have been described as

3523. White willow on a stream, holding the bank from washing. (See No. 7.)

growing in Europe. Although as many or even more species occur in America, fewer hybrids have been detected here. The hybrids described as growing in America are for the most part between native species and those introduced from Europe. Because of the hybridity and the fact that the sexes are separated, the genus *Salix* is considered to be very critical and difficult for the systematist.

The rôle that the willow plays in the north temperate regions is to a certain extent analogous to that of the eucalyptus in subtropical regions; it flourishes in wet ground and absorbs and transpires immense quantities of water. It has been used to plant around cesspools for sanitary effect. But while most of the species occur spontaneously in wet ground or along stream-banks, the willows may be cultivated in various situations. The white willow (*S. alba*) has been used very effectively to fix stream-banks against erosion. (Figs. 3523, 3524.) Its root-system is very extensive and when well established withstands the effect of heavy rapid streams as well as wave-action. *S. arctica* and several allied species are among the few woody plants extending into extreme arctic regions. The arctic species are among the most diminutive of woody plants. As one goes south the species increase in size. Some of the species of North Temperate, Tropical and South Temperate zones are large trees. The arborescent species all form wood very rapidly. Specimens of white willow which may not be of great age look venerable from their great thickness of trunk and size of top. The wood is light in weight and color, finely and evenly porous. The wood has been extensively used in manufacture of gunpowder. It has also been used for many other purposes. Certain species have been extensively cultivated for many years in Europe for materials with which to manufacture baskets. *S. viminalis* appears to be the favorite species for this purpose. Basket willow is now extensively planted in central New York, and considerable manufacturing of this material is under way. It is probable that the Chinese and Japanese willows recently described will yield useful forms for American planting; in *Plantæ Wilsonianæ*, III, pt. 1, describing Chinese plants, Schneider admits regularly 183 species.

As ornamental trees the willows present little variety. The bright yellow catkins of some species are attractive in spring. They are considerably used as "nurse trees"

nigra), is an adaptation to facilitate the natural distribution of the species. Certain it is that twigs broken from the tree by the wind are carried down streams and, becoming anchored in the muddy banks, grow readily. It is one of the most aggressive trees in occupying such places. Willows may also be propagated by seed. The

3525. Old roadside trees of *Salix alba*.

seeds are very small and contain a green and short-lived embryo. A very short exposure of the seeds to the air will so dry them out that they will not germinate. The safest way to secure seedlings is to plant the seeds as soon as the capsule opens.

KEY TO THE SPECIES.

- A. Species of the usual upright kinds.
- B. Scales of ament green, deciduous: mostly trees.
- C. Stamens more than 3.
- D. Foliage persistent. 1. *Bonplandiana*
- DD. Foliage not persistent.
- E. Buds small.
- F. Lvs. green beneath. 2. *nigra*
- FF. Lvs. glaucous beneath. 3. *amygdaloides*
- EE. Buds large: lvs. very shiny above. 4. *lucida*
5. *pentandra*
- CC. Stamens 2 or 3.
- D. Large trees. 6. *fragilis*
7. *alba*
8. *vitellina*
9. *babylonica*
10. *Salamonii*
11. *blanda*
12. *elegantissima*
13. *Safsaf*
- DD. Shrubs. 14. *longifolia*
15. *argophylla*
16. *balsamifera*

3524. Same tree as in Fig. 3523, in summer dress.

for slower-growing trees that require partial shade while young. The red and yellow branches of certain willows are very bright and cheering in winter. The weeping forms are very popular, but they are often planted with little sense of fitness. The cultural remarks under *Populus* will apply to willows.

The species of willows are readily propagated by cuttings. It has been suggested that the brittleness at base of twigs of some species, notably the black willow (*S.*

BB. Scales of ament black above, persistent: mostly shrubs.

C. Stamens 2.

- D. Caps. hairy.....17. *Caprea*
 18. *discolor*
 19. *rostrata*
 20. *humilis*
 21. *tristis*
 22. *sericea*
 23. *petiolaris*
 24. *viminialis*
 25. *candida*
 DD. Caps. glabrous.....26. *myrtilloides*
 27. *cordata*
 28. *irrorata*
 29. *incana*
 CC. Stamen 1.....30. *purpurea*
 31. *sitchensis*

AA. Species of the arctic-alpine kinds: dwarf often prostrate shrubs.....

32. *Cottetii*
 33. *herbacea*
 34. *myrsinites*
 35. *pyrenaica*
 36. *repens*
 37. *reticulata*
 38. *retusa*

1. *Bonplandiana*, Kunth. A branching shrub or low tree with coriaceous lvs. 5-6 in. long, dark green above and glaucous beneath: aments usually precocious in the axils of mature lvs. Native of Mex. and the S. W. U. S.

2. *nigra*, Marsh. BLACK WILLOW. Fig. 3526. Tree, 30-40 ft. high: bark flaky, often becoming shaggy: twigs brittle at base: buds small: lvs. lanceolate, green both sides, finely and evenly serrate: aments 1-2 in. long; scales oblong, deciduous; stamens 3-6; ovary ovate-conical, glabrous; style short but distinct. E. N. Amer. Var. *falcata*, Pursh. Lvs. elongated, narrow and falcate.

3. *amygdaloides*, Anders. PEACH-LEAF WILLOW. Tree, 30-40 ft. high: bark longitudinally furrowed, less inclined to be flaky: lvs. broader, glaucous beneath, on rather long, compressed petioles: aments loosely fld.; ovary lanceolate-conical; style very short. Cent. and W. N. Amer.

4. *lucida*, Muhl. Shrub or low bushy tree, 6-15 ft. high: branches yellowish brown and highly polished: buds large, flattened, and recurved at the apex: lvs. large, broadly lanceolate-acuminate, serrate, dark green, shining above: aments large, appearing with the lvs.; scale pale green, deciduous; stamens 4-5; ovary pedicelled, rather obtuse, glabrous. E. N. Amer.—A beautiful plant, deserving of more extensive cult.

5. *pentandra*, Linn. (*S. laurifolia*, Hort. 3. *Humboldtiana*, Hort. not Willd.). BAY-LEAF or LAUREL-LEAF WILLOW. Shrub or small tree, 8-20 ft. high: branches chestnut-color: lvs. large, elliptic to broadly oblanceolate, acuminate, shining and dark green above, paler beneath: aments appearing after many of the lvs. are fully developed, not conspicuous. Eu. and Asia.

6. *fragilis*, Linn. (*S. viridis*, Fries. *S. Russelliana*, Smith). BRITTLE WILLOW. Fig. 3526. Tree, 50-60 ft. high, excurrent in habit and of very rapid growth: branches brown, obliquely ascending: buds medium size, pointed: lvs. large, lanceolate-acuminate, glabrous or slightly hairy when young, scarcely paler beneath, glandular serrate: aments appearing with the lvs. (the staminate

3526. Leaves of willow. 1, *Salix petiolaris*; 2, *S. candida*; 3, *S. purpurea*; 4, *S. myrtilloides*; 5, *S. nigra*; 6, *S. fragilis*. ($\times \frac{1}{2}$)

tree rare in Amer.), seldom bearing good seed, slender; scales deciduous. Eu., N. Asia. Gn. 19, p. 517; 55, p. 89.—Frequently cult. and also growing spontaneously in many places. A company of promoters induced many American farmers to plant hedges of this willow some 50 years ago. Many of these occur now throughout the country, the trees being 40-50 ft. high. A stake cut from a tree and driven in the ground will soon establish itself and grow into a tree. Var. *decipiens*, Hoffm. Twigs yellow: buds black in winter: lvs. smaller and brighter green. Probably a hybrid with another species.

7. *alba*, Linn. WHITE WILLOW. Fig. 3527; also Figs. 3523-3525. Large tree, with short and thick trunk, not excurrent in habit: branches yellowish brown: lvs. ashy gray and silky throughout, giving a white appearance to the whole tree, 2-4 in. long, elliptical. Eu. Gn. 55, p. 87; 61, p. 7.—Heretofore associated with the next species, from which it differs in color of twigs and vesture and color of lvs., as also in its general habit. It is only occasionally seen in Amer. Var. *splendens*, Anders. (*S. alba* var. *argentea*, Wimm. *S. regalis*, Hort.). Lvs. densely silky on both sides, nearly silvery-white while young. The forms of this species not easily distinguishable from one another, can be readily distinguished from the following species.

8. *vitellina*, Linn. (*S. blanda*, Anders.). YELLOW WILLOW. Becoming a very large and venerable appearing tree, the rather short trunk often 4 ft. or more in diam. It is often pollarded. The crown is deliquescent and rounded in outline. Branches yellow: lvs. silky-hairy when young, glabrous when mature, glaucous beneath, the whiteness intensified after the lvs. fall: aments appearing with the lvs. Abundant in E. N. Amer. Mn. 8, p. 25 (erroneously as *S. alba*).—Displaying many variations, the most obvious of which are: Var. *aurea*, Salisb. (var. *aurantiaca*, Hort.), branches golden yellow, especially just before the lvs. appear in spring. Var. *britzensis*, Hort., bark red. These as well as other choice varieties are grafted. Var. *pendula*, Hort. (*S. aurea pendula*, Hort. *S. alba* var. *vitellina pendula*, Rehd. *S. babylonica aurea* and *S. babylonica ramulis aureis*, Hort.). Tree of weeping habit, similar to *S. babylonica*, with yellow branches. M.D.G. 1898: 88. Gn. 55, pp. 15, 22. S.H. 2:361, 371.

9. *babylonica*, Linn. (*S. pendula*, Moench). NAPOLEON'S WILLOW. Fig. 3527. A tree of weeping habit, 30-40 ft. high, with long slender olive-green or purplish branches: buds small, acute: lvs. 2-6 in. long, attenuate at base and apex: aments appearing with the lvs., slender, the pistillate green, 1 in. long, caps. small. China. Gn. 1, p. 371; 34, p. 527; 39, p. 73; 55, p. 92. S.H. 1:261. F.E. 19:574. G.W. 2, p. 31.—Long known in cult. and often grown in cemeteries. Tender N. Var. *annularis*, Forbes, lvs. twisted back so as to form a sort of ring.

10. *Salamonii*, Carr. (*S. babylonica* var. *Salamonii*, Carr.; sometimes erroneously spelled *Salomonii* or *Salmonii*). Hybrid between *S. alba* and *S. babylonica*. Similar to *S. babylonica*, but less pendulous: tree with ascending branches and pendulous branchlets: lvs. similar to those of *S. babylonica*, but sparingly silky-pubescent on both sides: pistillate catkins with more pubescent

axis and long-ciliate scabs. Originated in France. M.D.G. 1898:89. Gn. 55, p. 19. S.H. 2:373.—Probably *S. sepulcralis*, Simonkai, belongs here.

11. *blánda*, Anders. (*S. Pétzoldii*, Hort. *S. babylonica* var. *dolorosa*, Rowen; possibly also *S. pendulina*).—WISCONSIN WEEPING WILLOW. A hybrid of *S. babylonica* and *S. fragilis*. Tree with spreading limbs and pendulous branches; branches brownish green or brown: lvs. lanceolate or narrow-lanceolate, long-acuminate, serrulate, glabrous, dark green above, glaucous beneath, 3–6 in. long and $\frac{1}{8}$ – $\frac{3}{4}$ in. broad: fls. with the lvs.; stamens 2; ovary short-stalked, glabrous, with one gland at the base, half as long as the pedicel. Of garden origin.

12. *elegantissima*, Koch (*S. Sieboldii*, Hort.). THURLOW'S WEEPING WILLOW. Tree with more spreading habit and larger crown than *S. babylonica*: branches long and pendent, yellowish green, sometimes blotched with brown: appears to be more hardy than *S. babylonica*. Origin unknown. M.D.G. 1898:88. Gn. 55, p. 24. S.H. 2:363.—Said to be of Japanese origin; probably only a form of *S. blanda*.

13. *Sáfsaf*, Forsk. EGYPTIAN WILLOW. A tree in general appearance like *S. alba* or *S. babylonica*. Several varieties have been described. The mature lvs. are bright green above and glaucous beneath, 3–5 in. long and over $\frac{1}{2}$ in. wide. N. E. Afr., where it is frequently cult. along highways.—Intro. into Italy many years ago.

14. *longifolia*, Muhl. (*S. rubra*, Rich., not Huds. *S. interior*, Rowlee. *S. fluviatilis*, Sarg., and other recent authors in part, not Nutt.). Fig. 3527. Varying in stature from a low shrub to a small tree, usually growing along streams and lake-shores: twigs smooth and brown to densely tomentose and gray: buds plano-convex, with an obtuse and rounded apex, very small: lvs. nearly or quite smooth, sparsely canescent to extremely canescent, sessile, linear-elliptical, remotely dentate, the teeth narrow, sometimes quite spinulose: stipules conspicuous, ear-shaped, obscurely denticulate, deciduous: aments of late spring on short lateral peduncles, which bear 4–6 lvs., those borne later in the season on much longer leafy branches, very loosely fld.: fls. fasciated in clusters of 2–5 on the axis, a distinct interval between the fascicles, first appearing in May and often bearing a second set of aments in early summer; scales usually glabrous or somewhat hairy toward the base, narrowly oblong, yellowish, deciduous after flowering; filaments crisp-hairy below, smooth above: caps. sessile, clothed when young with appressed silvery hairs, becoming nearly smooth at maturity; stigmas short, sessile. Cent. N. Amer.—The pistillate ament, lax at anthesis, becomes more so as the caps. mature, and by this character the species can easily be distinguished from related species.

15. *argophylla*, Nutt. (*S. longifolia* var. *argophylla*, Anders. *S. fluviatilis* var. *argophylla*, Sarg. *S. Hindsiana*, Benth.). Tree or large shrub, 12–18 ft. high, forming dense thickets but not growing in clumps: branches nearly glabrous and exceedingly tough: bark turning from brown to bright yellow or orange just before blooming, making a thicket of it a most conspicuous object: lvs. narrowly lanceolate, closely sessile, entirely or rarely min-

utely and remotely denticulate, clothed equally on both sides with an appressed silky pubescence, which more or less conceals the veins; stipules obsolete: scales oblong and obtuse in the staminate ament, narrower and more acute in the pistillate; lower half of the filament densely crispy hairy: caps. lanceolate, covered with straight appressed silky hairs, closely sessile; stigmas sessile; mature caps. often nearly glabrous.—Occasionally the lvs. remain upon the plant over winter, the young shoots appearing in their axils in spring. Ament surpassed in length by its leafy peduncles; appearing in May in Ore. and N. Calif. and flowering intermittently all summer. This species is distinguished by its narrowly lanceolate, entire lvs., obsolete stipules, small and rather narrow aments, erose scales, and hairy caps. *S. argophylla* occurs on the Pacific slope from S. Calif. to Brit. Col. It is a western representative of the long-lvd. willows. Not advertised, but a beautiful species common along streams and irrigation ditches.

16. *balsamifera*, Barr. Fig. 3528. A much-branched clean-looking shrub, with shining colored twigs, sometimes almost tree-like: glabrous: lvs. short-oval to lance-oblong, rounded and sometimes somewhat cordate at base, glandular-serrulate, thinnish and fragrant, dark green above and pale or glaucous and also prominently reticulate beneath: fertile aments becoming lax and open, the slender pedicels of the carpels much longer than the glands, the style short. Along the northern borders of the U. S. and far northward; an attractive species. G.F. 6:29 (reduced in Fig. 3528).

17. *Cáprea*, Linn. GOAT WILLOW. Fig. 3529. A small tree, 12–25 ft. high, with upright branches: lvs. large, 2–5 in. long, 1–3 in. wide, rounded or subcordate at base, rugose, very variable: aments appearing before the lvs., large and showy, especially the staminate ones. Eu., Asia.—The typical form often occurs in yards where it has sprouted from the stock upon which the more popular but scarcely more ornamental variety, *pendula*, has been grafted. Var. *pendula*, Hort. KILMARNOCK WILLOW. Dwarfed form, grafted on stock about 4 ft. high, and forming a weeping shrub. Often planted in yards. *S. multinervis* is supposed to be a hybrid, and probably belongs with *S. Caprea*. *S. Caprea* var. *tricolor*, Hort., is said by F. W. Kelsey to be a round-headed tree, with "tricolored foliage," probably a form of *S. aurita*. *S. palmifolia*, Hort., is said by F. W. Kelsey to be of vigorous growth, with large, deep green lvs. and reddish purple young wood.

18. *discolor*, Muhl. PUSSY WILLOW. Figs. 3521, 3522, 3527. A shrub or short-trunked tree, 10–20 ft. high: buds very large and nearly black: lvs. smooth and bright green above, whitish beneath, irregularly crenate-serrate: aments appear early in spring, before the lvs., closely sessile, enveloped in long, silky hairs. E. N. Amer.—Worthy of more extended cult. and thriving in dry ground.

19. *rostrata*, Rich. (*P. Bebbiana*, Sarg.). Fig. 3527. A small tree, 10–20 ft. high, with short but distinct trunk: buds of medium size, conical, brown: lvs. dull green and downy above, prominently veined and hairy beneath: aments appearing with the lvs., the staminate beautiful golden when in flower; scales narrow

3527. Leaves of willows. 7, *Salix alba*; 8, *S. babylonica*; 9, *S. longifolia*; 10, *S. rostrata*; 11, *S. tristis*; 12, *S. discolor*. ($\times \frac{1}{2}$)

and shorter than the pedicels: caps. long-rostrate. E. N. Amer.—Prefers dry soil and can be used to good advantage against walls and in rockeries.

20. *humilis*, Marsh. PRAIRIE WILLOW. A shrub, 3–8 ft. high, varying much in stature, and in size and shape of lvs.: branches hairy: lvs. oblanceolate to oblong, nearly entire, more or less revolute: aments densely and many-fld. E. N. Amer.—Grows in driest situations.

21. *tristis*, Ait. DWARF WILLOW. Fig. 3527. A diffuse shrub, 1–1½ ft., with long deep-set root: branches gray, slender: lvs. small, 1 in. long, linear-lanceolate, very short-petioled: aments small and rather few-fld.; stamens orange-red. E. N. Amer.

22. *sericea*, Marsh. SILKY WILLOW. A shrub usually 4–8 ft. high, diffusely spreading from base: branches often reddish: buds obtuse and rounded at apex, cylindrical: lvs. very silky beneath, sometimes becoming less so at maturity: aments densely fld., appearing with the lvs.; stamens often orange-red: caps. short-pedicelled, ovate-oblong, nearly truncate at apex. N. E. N. Amer.

23. *petiolaris*, Smith, not Hort. Fig. 3526. A low shrub, 3–5 ft. high: branches slender, the whole plant much slenderer than *S. sericea*, with which it frequently grows: buds smaller and more pointed: lvs. only slightly silky when young, soon glabrous, more evidently toothed: aments rather loosely fld.: caps. rostrate and pointed, distinctly pedicelled. Cent. and N. E. N. Amer.—*S. petiolaris* of the trade is *S. incana*.

24. *viminàlis*, Linn. OSIER WILLOW. A shrub or small tree, 10–20 ft. high: branches slender and straight: lvs. linear-lanceolate, beautifully silvery, 4–10 in. long; margins revolute, entire: aments appearing before the lvs., golden yellow. Eu., Asia.—Most often seen in plantations for basket material, for the production of which the plants are cut near the ground every year. Willow-culture in experienced hands is often profitable. (For

details, see Simpson, Osier Culture, Bull. 19, Div. of For., U. S. Dept. Agric. 1898.) This species does not thrive in this country as well as in Eu.

25. *cándida*, Fluegge. HOARY WILLOW. Fig. 3526. A shrub, 2–5 ft. high: young branches hoary, becoming smooth and red with age: buds reddish, rounded at the

3529. Staminate catkins of goat willow.—*Salix Caprea* ($\times \frac{1}{2}$). No. 17.

apex: lvs. lanceolate or linear-lanceolate, 2–4 in. long, dark green and wrinkled above, covered below with dense white tomentum, revolute: aments sessile, appearing before the lvs.; staminate of reddish anthers: caps. densely white-woolly, with red style and stigmas. N. Amer.—This species hybridizes freely with *S. cordata*, and several natural hybrids have been described.

26. *myrtilloides*, Linn. Fig. 3526. A shrub, 2–5 ft. high, with rather slender brown twigs: lvs. oblong or elliptic-obovate, usually obtuse at both ends, entire and smooth, reticulate-veined: aments rather few-fld.: caps. reddish, glabrous. N. E. N. Amer. and Eu. Usually grows in cold peat-bogs.—Probably not in cult. The plant sold under this name is probably some form of *S. purpurea*, which *S. myrtilloides* closely resembles in general appearance.

27. *cordata*, Muhl. (*S. rigida*, Muhl.). HEART-LEAVED WILLOW. Fig. 3530. A large shrub or small tree, 10–30 ft. high: branches stout: buds large, flattened against the branch: lvs. oblong-lanceolate, green on both sides, finely serrate, glabrous and rather rigid at maturity: aments rather slender, appearing with the lvs.: caps. glabrous, greenish or brownish. N. Amer.—This is a variable species and undoubtedly some of the forms included in it are hybrids; several supposed natural hybrids have been described. Var. *péndula*, Hort., is a decumbent form.

28. *irroràta*, Anders. COLORADO WILLOW. A dense diffuse shrub, 8–12 ft. high: branches stout, covered with a white bloom: buds large: lvs. linear-lanceolate, 3–4 in. long, ½ in. wide, green above, glaucous beneath, undulate serrate: aments all appearing before the lvs., sessile, very densely fld.; staminate golden yellow: caps. glabrous, nearly sessile. Rocky Mts.

29. *incàna*, Schrank (*S. petiolaris*, and *S. rosmarinifolia* of American gardeners, but not of botanists). Shrub or small round-topped tree, with long, slender branches: lvs. linear, revolute, 2–5 in. long, very narrow, green above, white-tomentose beneath: aments long and slender, appearing with the lvs.: caps. glabrous; filaments of stamens more or less connate. Eu.—This species is frequently grafted upon hardy stock (*S. Caprea*) when sold from nurseries.

30. *purpurea*, Linn. (*S. Forbyàna*, Smith. *Vetrix purpurea*, Rafin.). PURPLE OSIER. Fig. 3526. A shrub or small tree, spreading at base, with long, flexible branches: lvs. oblanceolate, serrulate, glabrous, veiny, 3–6 in. long, often appearing opposite: aments sessile, slender; pistillate recurved; scales purple; stamen 1: caps. small, ovate. Eu.—Planted as an ornamental shrub and escaped in many places. Also grown as a basket-willow. Var. *péndula*, Dipp. (*S. nigra péndula*, Hort. *S. americana péndula*, Hort.). Branches pendent. Gng. 4:243.

3528. *Salix balsamifera*. ($\times \frac{1}{2}$)

31. *sitchensis*, Sans. SITKA WILLOW. A shrub, 10-12 ft. high and more: lvs. obovate, glabrous, clothed beneath with silky hairs which have a beautiful satiny luster: aments appearing with lvs., long, cylindrical and graceful, also satiny. N. W. N. Amer.—This willow, which, so far as known, has not been used as an ornamental plant, is one that would be at once novel and beautiful. The characteristic luster of the lvs. is preserved in plants in cult.

3530. Leaves of *Salix cordata* showing stipules. ($\times \frac{1}{4}$)

32. *Cottetii*, Kerner. A low shrub differing from *S. retusa* mainly in the larger size of the whole plant as well as its lvs. Cent. Eu. G.W. 9, p. 542.

33. *herbacea*, Linn. A very dwarf species usually not more than an inch or so in height, forming dense mats: lvs. orbicular, serrate, usually emarginate at both base and apex. Alpine regions of Amer. and Eurasia, White Mts., N. H.

34. *myrsinites*, Linn. (*S. Jacquinii*, Host). An alpine shrub a foot or less high, either erect or more or less creeping: lvs. short-petioled, lanceolate, coriaceous, shining, green both sides. Arctic and alpine regions.

35. *pyrenæica*, Gouan. A dwarf caulescent shrub usually more or less depressed in habit, with slender brown shining twigs: lvs. membranous, about 1 in. long and half as wide, entire, ciliate on the margin. In the alpine regions of the Pyrenees.

36. *repens*, Linn. A shrub of variable stature and vesture: lvs. oval to linear, entire or remotely serrulate, shining above, silver-silky or glabrous beneath, stipules wanting. N. Eu. and Asia. Var. *argentea* has silvery-silky lvs. G.L. 22:325.

37. *reticulata*, Linn. A depressed shrub with few oval or orbicular lvs. glaucous beneath, green above, rugose-reticulate: aments slender, borne on a long peduncle. Arctic regions of both hemispheres.

38. *retusa*, Linn. (*S. serpyllifolia*, Scop.). A depressed shrub: lvs. characteristically "parallel"-veined, obtuse or slightly retuse at the apex, entire, less than $\frac{1}{2}$ in. wide. Alpine regions of Eu. and Asia.

S. aglaja, Hort.—*S. daphnoides*.—*S. amygdalina*, Linn. (*S. triandra*, Linn.). Usually shrubby, to 12 ft.: branchlets glabrous, rarely slightly silky: lvs. lanceolate, glaucous, pale green or bluish below, to 5 in. long: fls. shortly before or with the lvs.; stamens 3; ovary long-stalked, glabrous. Eu.—*S. Bakeri*, Seemen, is probably a form of *S. lasiolepis*.—*S. Böckii*, Von Seemen. An ornamental dwarf species: lvs. oblong or oval, $\frac{1}{4}$ – $\frac{1}{2}$ in. long, mucronate, dark green and glabrescent above, silvery with silky appressed hairs beneath: aments 1–2 in. long, produced in Oct. and Nov. before the fall of the lvs. China.—*S. chrysocoma*, Dode, is a hybrid between *S. babylonica* and *S. vitellina*.—*S. daphnoides*, Vill. Ten to 20 ft. high: twigs violet: lvs. narrow-oblong or linear-lanceolate, very acuminate, 3–6 in. long.—*S. Hanksenii*, Dode. Apparently a natural hybrid between a species of the group of *S. nigra* and one of the group of *S. babylonica*.—*S. heterandra*, Dode. Possibly hybrid between a species of the *S. purpurea* group and one allied to *S. pentandra*. Shrub: lvs. lanceolate-obovate or narrowly lanceolate, 3–4 in. long, remotely serrate, glabrous, light green above, whitish-glabrous beneath: male aments about $\frac{1}{4}$ in. long: Caucasus.—*S. hypolepis*, Seemen. Shrub, to 10 ft.: lvs. elliptic to lanceolate, acute, glabrous at maturity, glaucous below, 1–2 in. long: aments with the lvs. 1–2 in. long. Cent. W. China.—*S. japonica*, Thunb. (*S. babylonica* var. *japonica*, Anderss.). Shrub, to 6 ft.: lvs. ovate-oblong to lanceolate, remotely serrate, glabrous, grayish green beneath, to 3 in. long: aments slender, $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long; ovary glabrous. Japan.—*S. lasiolepis*, Benth. ARBORE WILLOW. Shrub or tree, 8–25 ft. high: lvs. oblong, suborbicular, obovate or linear acute, obscurely serrulate, $1\frac{1}{2}$ –5 in. long: aments appearing before the lvs., sessile, densely silky-tomentose in the bud, suberect: caps. glabrous or puberulent, short-pedicelled. Calif.—*S. lasiocladus*, Dode. Lvs. ovate-lanceolate, about $2\frac{1}{2}$ in. long, serrate, light green and shining above, whitish glaucous beneath: male aments appearing late. Caucasus.—*S. magnifica*, Hemsl. Shrub, to 20 ft.: lvs. oval to obovate, shortly and obtusely acuminate, glabrous, pale beneath, to 8 in. long and to 5 in. wide; petiole purplish: staminate aments to 7 in., pistillate to 11 in. long. W. China. A remarkable willow, but tender N. J.

H.S. 39, p. 137, fig. 148.—*S. Matsudana*, Koidzumi (*S. babylonica* var. *pekinensis*, Henry). Tree, to 40 ft.: branchlets ascending or pendulous, greenish: lvs. narrowly lanceolate, serrulate, glabrous, 2–4 in. long: aments with the lvs., about $\frac{1}{2}$ in. long. N. E. Asia.—*S. Medemii*, Boiss., of the Armenia-Persia region is an upright species 12 ft. and more high with oblong somewhat serrate lvs. abruptly pointed.—*S. Medvedevii*, Dode. Shrub or small tree: lvs. very narrow, up to 4 in. long: female aments appearing late, cylindric, $1\frac{1}{4}$ in. long. Caucasus.—*P. özica*, Dode. Lvs. large, glaucous, giving the tree a bluish appearance. Cent. Asia.—*S. persica*, Boiss. Similar to *P. babylonica*. Trunk pale ashy gray or brownish: lvs. very shortly stalked, somewhat falcate, long-acuminate, serrulate. Persia.—*S. Rehderiana*, Schneid. Shrub, to 10 ft.: branchlets sparingly hairy or glabrous: lvs. lanceolate, crenulate, whitish and silky beneath, with yellow midrib, 2–5 in. long: aments precocious, about 1 in. long; anthers purple at first; ovaries glabrous. W. China.—*S. renècia* is a hybrid, of which *S. cinerea* is a parent.—*S. Tominii*, Dode. Tree with spreading branches: lvs. obovate to lanceolate, $3\frac{1}{4}$ –4 in. long or more, remotely serrate: male aments at first conical and rosy at apex, afterward ovate-cylindric, $\frac{1}{4}$ in. long. W. Asia.—*S. triandra*, Linn.—*S. amygdalina*.—*S. Wallichiana*, Anderss. Shrub or small tree: lvs. ovate to oblong-lanceolate, entire, silky beneath like the young branchlets, 2–3 in. long: staminate aments 1 in. long, pistillate 3–5 in.; caps slender, silky. Himalayas, Cent. and W. China.—*S. zygostemon*, Hook. f. & Thom. Probably a natural hybrid between *S. purpurea* and *S. Medemii*.—*S. Wentworthii*, Hort., is described as a tall upright rapid-growing willow with bright red bark: botanical position to be determined.

W. W. ROWLEE.

SALPICHROA (Greek, *tube* and *skin*; in reference to the form and texture of the flower). Syn. *Salpichroma*. *Solanaceæ*. Shrubs, subshrubs, or herbs, sometimes grown in the warmhouse and now used for outdoor planting in southern California.

Leaves often small, entire, long-petioled: fls. white or yellow, 2–3 in. long (Section *Eusalpichroa*) or only about $\frac{1}{2}$ in. long (Section *Perizoma*); calyx tubular or short, 5-cleft or -parted, the lobes linear; corolla tubular or urn-shaped, without a crown in the throat; lobes 5, acute, often short induplicate-valvate; berry ovoid or oblong, 2-celled; seeds numerous, compressed.—About 10 species, extra-trop. S. Amer. The species described below is said to have the advantage of being an exceedingly rapid climber, covering walls within one season with a thick mass of foliage and will thrive in alkali soil and under intense heat. The small white berries are sold everywhere in Paraguay as "cock's eggs." It grows with astonishing rapidity from the fleshy roots, which, however, are destroyed by frost. If black scale secures a foothold, it is well to cut the plant down to the roots.

rhomboidea, Miers (*Salpichroma rhomboideum*, Miers). A half-hardy climber, somewhat woody, with green, flexuous branches: lvs. small (blade $\frac{1}{2}$ – $\frac{3}{4}$ in. long), ovate-rhomboid: fls. small, usually less than $\frac{1}{2}$ in. long, solitary, nodding, white; corolla short, constricted at the middle and at the throat, and bearing on the inside a fleshy, woolly ring: berry ovate-oblong, yellowish or white, edible, but of poor flavor. Argentina. G.C. III. 24:450. R. H. 1897:531. Gn. 35, p. 367. F.E. 32:448.—The plant appears to be offered as *Withania origanifolia*, although the genus *Withania* itself has good standing.

F. W. BARCLAY.

3531. *Salpiglossis sinuata*. ($\times \frac{1}{4}$)

SALPIGLÓSSIS (Greek, *tube* and *tongue*; alluding to the form of the corolla and the appearance of the style). *Solanaceæ*. Viscous-pubescent half-hardy annual, biennial, or perennial herbs, chiefly used for garden flowers, but sometimes also grown in the greenhouse; of rich and attractive colors.

Plants about 18 in. high, erect, covered with short glandular hairs: lvs. entire, wavy-margined, dentate or pinnatifid; fls. long-stemmed, large, funnel-shaped, ranging in color from various shades of purple and blue through numerous reds and yellows to creamy white, and usually beautifully marbled and penciled with several colors; calyx tubular, 5-cleft, corolla funnel-form, widely bell-shaped at the throat; lobes 5, plicate, emarginate; stamens 4, didynamous: caps. oblong or ovoid; valves 2-cleft.—About 8 species, natives of Chile.

The usual species in cultivation is *S. sinuata*, which was formerly divided into about 6 species mainly on the color of the flowers. *S. sinuata* has greatly improved in size of flowers and range of color until it is at the present time amongst the very finest half-hardy annuals. The varieties of salpiglossis require the general

treatment given half-hardy annuals. They prefer a deep light rich soil not given to sudden extremes of moisture and dryness. The seeds may be sown indoors by the middle of March or later, or may be sown outdoors in early spring. Care must be taken that the early sown plants do not become stunted before being planted out. They bloom for several weeks in late summer. The flowers are useful for cutting and last well. The plant is also excellent as a greenhouse annual for late winter bloom. Seeds for this purpose may be sown in late summer. (F. W. Barclay.)

sinuata, Ruiz and Pav. (*S. variabilis*, Hort. *S. Barclayana*, Sweet. *S. hybrida*, Hort. *S. grandiflora*, Hort.). Fig. 3531. Hardy annual, 1-2 ft. high, suberect, branched,

3532. Salsify or vegetable oyster. ($\times \frac{1}{2}$)

sticky-pubescent, with fls. 2 in. long and wide, ranging from straw-color and yellow through scarlet nearly to blue, with great variation in venation and markings: lower lvs. petiolate, elliptic-oblong, wavy-toothed or pinnately cut; upper lvs. more nearly entire: bracts sessile, entire. Vars. *azúrea*, *aúrea*, *coccinea*, *púmila*, *nàna*, Hort., are offered. V. 23:129. Gn. 29:166; 40, p. 75. R.H. 1849:361. G. 14:269. Gn.W. 22:659; 25:586. J.F. 4:395. Var. *superbissima*, Hort., has a more columnar manner of growth with a thick, unbranched stem. G.C. III. 22:363. A.G. 18:860.

S. atropurpurea, Graham. St. procumbent at base, then erect, about 2 ft. high: lvs. scattered, various in shape, lanceolate-elliptical, elliptical, or ovate-elliptical, flaccid, sinuated, the segms. generally blunt and entire: fls. deep rich purple on rather long pedicels. Chile. B.M. 2811. Included in *S. sinuata* by many authorities.—*S. straminea*, Hook. (*S. picta*, Sweet. *S. straminea* var. *picta*, Hook.). Included in *S. sinuata* by many authorities from which it differs in the color of the corolla, which is whitish tinted yellow at the throat and often purple-veined. The top of the style of *S. straminea* is toothless while that of *S. sinuata* is toothed. Chile. B.M. 3365. Probably not in the trade.

F. TRACY HUBBARD.†

SALPÍNGA (Greek, *trumpet*, referring to the shape of the calyx). *Melastomaceæ*. Erect glabrous branching herbs, including the warmhouse foliage plant known to the trade as *Bertolonia margaritacea*.

Leaves often unequal, oblong or lanceolate, long-petioled, under surface plum-colored: fls. spicate, on terminal, simple or dichotomously branched peduncles, secund, sessile or pedicellate; calyx glabrous, tube tubular or campanulate, 10-ribbed, the lobes short, tuberculate outside; petals 5, oblong or obovate; stamens 10; ovary free, oblong, 3-celled: caps. 3-edged, included in the terete, thickened, ribbed calyx.—Four species, Guiana, Brazil, and Peru.

margaritacea, Triana (*Bertolonia margaritacea*, Hort. Bull. *Gravèsia guttata* var. *margaritacea*, Nichols.). Tender perennial herb: st. $1\frac{1}{2}$ -4 in. high, erect, obtusely 4-angled, simple: lvs. long-petiolate, thin-membranaceous, ovate, base rounded or frequently distinctly emarginate-cordate, upper surface dark dull green, white-spotted between the veins, lower surface pale green, reddish or bright rose: cymes terminal, slender-branched, the branches red, rather long; fls. white or sometimes whitish rose; calyx-tube purplish, 10-ribbed, the ribs red; segms. green with pink tips; petals erect or erect-spreading, acute or rather obtuse: caps. pale, obscurely 3-sided. Brazil. F.S. 16:1697.

S. longifolia, Triana (*Bertolonia longifolia*, Cham.). St. short, herbaceous: lvs. oblong, rarely ovate-oblong, base rounded or slightly cordate, upper surface bright green, glabrous, lower surface paler, scurfy-pubescent: cymes terminal; fls. white: caps. pale, 3-sided. Brazil.—*S. secunda*, Schrank & Mart. St. subshrubby, erect: lvs. narrow-ovate or ovate-oblong, base rather obtuse or short-alternate, upper surface light green, lower surface paler: cymes terminal and axillary; fls. unknown: caps. pale red-brown, narrowly oblong, subcylindrical. Brazil.

F. TRACY HUBBARD.

SALSIFY (formerly sometimes spelled *salsafy*) is *Tragopogon porrifolius*, one of the *Compositæ*. Fig. 3532. A garden esculent, grown for the fleshy root. This root has the flavor of oysters, hence the plant is sometimes called vegetable oyster and oyster plant.

Salsify is perfectly hardy. The seeds (which are really fruits) are sown in early spring, about as soon as the soil can be prepared, in drills where the plants are to stand. The drills may be 2 to 3 feet apart, if tilled by light horse-tools, or half that distance if tilled only by hand. In the rows, the plants are thinned to stand 3 to 6 inches apart. The plant requires the entire season, in the North, in which to grow. The roots may be allowed to remain in the ground until spring, for freezing does not harm them. In fact, they are usually better for being left in the ground, because they do not shrivel and become tough as they often do in storage. If they are kept cool and moist in storage, however, the quality is as good as when the roots remain in the ground. At least a part of the crop should be stored, for the table or the market during winter and early spring.

The plant is biennial. The second spring, a strong stalk 2 to 3 feet tall is sent up from the crown of the root, and in spring or early summer an abundance of light purple flower-heads are produced. The flowers, or heads, close about noon. The leaves are long, linear, and grass-like. The roots are small, well-grown specimens being about 1 foot long and unbranched, and about 2 inches in diameter at the top. The skin is grayish white. Salsify is easy to grow, and it has no serious pests. It is a vegetable of secondary importance commercially, although it should be in every home-garden, particularly in the North, where it thrives best. Eight to ten pounds of seed is sown to the acre. There are few varieties, and these have no marked characteristics except in size. The Mammoth Sandwich Island and Improved French are probably the best varieties. Salsify is native to southern Europe. In some places it has escaped as a weed. See *Tragopogon*.

Black salsify is *Scorzonera*; Spanish salsify is *Scolymus*.

L. H. B.

SÁLSOLA (Latin, *salsus*, salty; the plants grow in salty places). *Chenopodiaceæ*. Weedy annual and perennial branching herbaceous plants of some 50 species of very wide distribution, mostly on seashores and in saline soils, of no horticultural interest. Lvs. narrow, usually awl-shaped or long-pointed, commonly fleshy:

fls. very small, sessile in the axils (Fig. 3533), perfect, provided with 2 bractlets; calyx 5-parted, the segms. winged on the back; petals 0; stamens usually 5; styles 2: fr. a flattened utricle, with a horizontal seed. Of interest because it includes the Russian thistle, *S. Káli*, Linn., var. *tenuifolia*, Mey. (*S. péstifer*, Nels.), now a widespread weed along railway rights of way and very abundant in the prairie and plains regions; of relatively recent intro. from Eurasia. With good tillage and short rotations it is not to be feared; when young or growing, it may have some value as forage. It is a bushy annual (Fig. 3534), and when broken off in autumn forms one of the tumble-weeds, and is carried long distances before the wind.

SÁLVIA (Latin name used as far back as Pliny, meaning to be well or healthy, referring to the medicinal properties of some species). *Labiátæ*. SAGE. Herbs, subshrubs, and shrubs, certain of which are of economic use, such as sage and clary, while others are grown for ornament both indoors and out.

Leaves entire, dentate-incised or pinnatisect; the floral lvs. are frequently changed to bracts, rarely similar to the cauline lvs.: floral whorls 2- to many-fld., variously arranged, spicate, racemose, paniculate or rarely all axillary: fls. variously colored, rarely yellow, and various-sized from large and showy to minute; calyx ovoid, tubular or campanulate, 2-lipped; corolla-tube included or exserted, limb 2-lipped; perfect stamens 2, the connective linear, transversely articulate with the filament; nutlets ovoid-3-edged or rather compressed, smooth.—Upward of 500 species widely distributed in the temperate and warmer regions of both hemispheres. *Salvia* was monographed in 1848 by Bentham in DC. Prod., vol. 12, and an index to the 407 species therein described is found in Buek's *Genera, Species et Synonyma, etc.*, pars iii. In 1876, Hemsley gave an account in *The Garden* (9:430-4) of 65 species which had been in cult. up to that time. See also *A Synopsis of the Mexican and Central American Species of Salvia*, by M. L. Fernald (Proc. Am. Acad. Arts Sci., vol. 35, 1900, and Contrib. Gray Herb. Harvard Univ. N. S. No. 19). In the work just cited 209 species are described and there is an elaborate key. Within the generic limits of *Salvia* the variation is astonishing. The color of the fls. ranges from scarlet through purple and violet to azure-blue, white and even pale yellow, but there seems to be no good pure yellow. Fig. 3535 indicates something of the range in form of corolla and calyx. Some fls. gape wide open, others are nearly tubular. In some the upper lip is longer than the lower, in other cases the lower lip is

longer than the upper. The lower lip is always 3-lobed, but frequently it does not appear to be so, for the lateral lobes are much reduced while the midlobe is greatly enlarged, often deeply lobed, and becomes the showy part of the fl. The calyx is small and green in some, large, colored, and showy in others. In many cases, as *S. leucantha*, the corolla and calyx are of different colors. The bracts range from minute and deciduous to a larger size and more attractive color than the fls. There are usually about 6 fls. in a whorl, sometimes 2, sometimes many. In spite of these and many other wide variations, few attempts have been made to split up *Salvia* into many genera, presumably from the feeling that the structure of the stamens makes the *Salvias* a natural, not an artificial group.

Cultivation of salvias. (Wilhelm Miller.)

Three salvias are cultivated for their leaves, which are used in seasoning and also in medicine. These are the common sage, *S. officinalis*; clary, *S. Sclarea*; and *S. Horminum*. For commercial cultivation of *S. officinalis*, see *Sage*.

Clary is a perennial plant, but is cultivated as an annual or biennial. The plants run to seed the second year, after which it is better to pull up the old plants. The seed may be sown in spring, in drills 12 to 20 inches apart or in a seed-bed, from which the seedlings are pricked out in May. In August the first leaves may be gathered and the plants will continue to yield until June or July of the following year.

Clary (*S. Sclarea*) and its near relative, *S. Horminum*, are plants of exceptional interest. They are cultivated for their culinary and medicinal value and also for ornament, but their ornamental value lies not in the flowers (which are usually insignificant) but in the colored bracts or floral leaves at the tops of the branches. The various varieties are known as the Purple-top clary, Red-top clary or White-top clary; also Red sage and Purple sage. The two species (*S. Sclarea* and *S. Horminum*) seem to be much confused in the catalogues.

Among the salvias grown for ornament there are two large cultural groups, the hardy and the tender. The hardy species are mostly border plants, blooming in spring and early summer. The tender species are

3533. Sprig of Russian thistle. (Natural size)

3534. Plant of Russian thistle.

generally used for summer bedding, sometimes for conservatory decoration in winter. Many of them bloom in summer and late fall, especially when they are treated as half-hardy annuals.

As regards color of flowers, there are also two important groups, the scarlet-flowered, and the kinds with blue, purple, violet, white, or variegated flowers. Of the scarlet kinds, *S. splendens* is the most called for; of the blue-flowered kinds, *S. patens* is the most popular of the bedding class, and *S. pratensis* the most sought of the hardy class. *S. patens* probably has the largest flowers of any of the blue-flowered kinds in cultivation.

The most widely used of all salvias cultivated for ornament is *Salvia splendens*, or scarlet sage. This is

one of the most brilliant red-flowered bedding plants in cultivation. It is generally grown in large masses. It does best in full sunshine, but may be used in shady places to light up dark woody recesses. It should have a dark background of some kind by way of contrast. A well-managed mass of scarlet sage may be maintained in full splendor from the middle of July to frost. It is propagated by either cuttings or seed. It is rather troublesome to keep cuttings or plants over winter, as they are particularly liable to attacks of aphid and red-spider. It is, therefore, important to get seed of an early-blooming variety of compact habit, and to sow the seed early indoors or in a frame in time to get good plants to set outdoors in May. A good raceme is over a foot long, with 30 or more flowers in a raceme, and 2 to 6 flowers in a whorl, each flower being 2 inches or more long. Some varieties have erect racemes, others pendulous, and there are white varieties, together with some intermediate colors. A poorly managed bed of scarlet sage gives a few flowers in September and is cut off in a short time by frost. Wet seasons delay the bloom, and, if the soil is too rich in nitrogen, the plants will make too much growth and the flowers will be late and relatively few. The same principles of cultivation apply to other tender salvias used for bedding. Florists sometimes lift a few plants of scarlet sage before frost, pot them and find that they make attractive plants under glass for a month or two. One advantage that *S. splendens* has over many other red-flowered salvias is that its calyx is as brilliant scarlet as the corolla.

KEY TO SUBGENERA AND SECTIONS.

- A. Corolla without a hairy ring inside.
 B. Anterior portion of connectives deflexed, linear, longitudinally connate or closely approximate.
 Subgenus III. JUNGIA.
 Section 7. CALOSPHERE. Species 27-46.
 BB. Anterior portion of connectives deflexed, abruptly dilated, connected at the callous extremity.
 Subgenus II. SCLAREA.
 C. Calyx ovoid, the upper lip concave, 2-grooved, teeth 3, very short and connivent.
 Section 6. PLETHIOSPHERE. Species 18-26.

- CC. Calyx tubular or campanulate.
 D. Upper lip of calyx truncate, the teeth small and remote; upper lip of corolla erect and concave. Section 4. HORMINUM. Species 12.
 DD. Upper lip of calyx 3-toothed, the teeth straight, scarcely connivent, the middle one often very small.
 Section 5. ÆTHIOPIS. Species 13-17.

- AA. Corolla with a hairy ring inside.
 B. Anterior portion of connectives connected, connate or approximate. Subgenus I. SALVIA.
 C. Calyx-teeth scarcely altered in fr., the upper lip of calyx subentire, somewhat 3-toothed.
 D. Upper lip of corolla erect, almost straight, concave. Section 1. EUSPHERE. Species 1-4.
 DD. Upper lip of corolla bent or falcate, compressed.
 Section 3. DRYMOSPHERE. Species 7-11.

- CC. Calyx-teeth membranaceous-dilated in fr., the upper lip of calyx 3-cleft or 3-toothed; upper lip of corolla erect or weakly bent, not or scarcely compressed.
 Section 2. HYMENOSPHERE. Species 5, 6.

- BB. Anterior portion of connectives remote.
 Subgenus IV. LEONIA.
 C. Connectives very short, deflexed and subulate anteriorly. Section 12. HEMISPHERE. Species 52.
 CC. Connectives directed forward, bearing fertile anther-cells anteriorly.
 D. Floral lvs. deciduous; bracts minute.
 E. Upper lip of calyx entire or minutely 3-toothed.
 Section 11. NOTIOSPHERE. Species 51.

- EE. Upper lip of calyx truncate, 3-toothed.
 Section 10. HETEROSPHERE. Species 49, 50.

- DD. Floral lvs. persistent and imbricated.
 E. Lvs. and bracts spiny.
 Section 8. ECHINOSPHERE. Species 47.
 EE. Lvs. and bracts not spiny.
 Section 9. PYCNOSPHERE. Species 48.

Subgenus I. SALVIA.

All Old-World species.

Section 1. EUSPHERE.

Shrubs or subshrubs, rarely herbs.

- A. Lvs. all entire.
 B. Calyx viscoso-pubescent..... 1. *Candelabrum*
 BB. Calyx villous or pubescent but not viscoso.
 C. Base of the oblong lvs. narrow-rotundate..... 2. *officinalis*
 CC. Base of the ovate lvs. broad-rotundate or cordate..... 3. *grandiflora*
 AA. Lvs., at least the lower, pinnatisect.... 4. *ringens*

1. *Candelabrum*, Boiss. Subshrub, half-hardy: st. shrubby at base, villous: lvs. entire, petiolate, oblong, both surfaces villous, canescent-tomentose beneath: panicle elongated, lax; the floral whorls remote, 3-5-fld.; calyx pedicellate, campanulate, somewhat 2-lipped, 5-toothed, viscoso-pubescent; corolla with the upper lip yellowish, whitish streaked, the lower violet. July. S. Spain. B.M. 5017. F.S. 13:1344.

2. *officinalis*, Linn. SAGE. Hardy, white-woolly subshrub, 6-12 in. high: sts. shrubby, the flowering branches tomentose-pubescent: lvs. entire, 1-1½ in. long, petiolate, oblong, base narrowed or rotund, the lower white-tomentose or lanate beneath or on both surfaces; the floral lvs. sessile, ovate, acuminate at the base, membranaceous, striate: racemes subsimple; floral whorls few, many-fld., distinct; calyx campanulate, membranaceous-colored, striate, pubescent or villous, the teeth subulate-acuminate; corolla purple, blue or white. Medit. region. June.—A common and variable species. Var. *albiflora*, Alef., has lvs. 3-4 times as long as broad: fls. white. Var. *aurea*, Hort., is a compact rather dwarf form about 1 ft. high, with golden yellow foliage. Var. *aurea variegata*, Hort., is offered in the trade. Var. *crispa*, Alef., has broad, crisped and variegated lvs. Var. *icterina*,

Alef., has green-and-gold lvs. Var. *latifolia*, Alef., has lvs. twice as long as broad; one of the common cult. forms. Var. *Milleri*, Alef., has rather red and spotted lvs. Var. *purpurascens*, Alef., has somewhat reddish foliage and is said to be preferred in England for kitchen use on account of its strong and pleasant taste. Var. *rubriflora*, Alef., has lvs. 3-4 times as long as broad, and red fls. Var. *salicifolia*, Alef., has lvs. 4-7 times as long as broad. Var. *sturnina*, Alef., has green-and-white lvs. Var. *tricolor*, Vilm. (*S. tricolor*, Hort., not Lem.), has lvs. of three colors, gray-green, veined with yellowish white and flesh-pink, later becoming velvety rose-red or deep red.

Var. *tenuior*, Alef., has lvs. about 3-4 times as long as broad and blue fls. This is the form commonly cult. as a kitchen herb.

3. *grandiflora*, Etling. Shrub, 2 ft. or more high: st. woody, white-lanate; the flowering branches tomentose: lvs. entire, petiolate, ovate, acute, the base broad-rotund or cordate, pubescent, the lower ones lanate beneath; floral lvs. herbaceous or the uppermost membranaceous, ovate, acute: racemes subsimple; floral whorls 6-10-fld., distinct; calyx campanulate, colored, striate hispid; corolla blue. June, July. Asia Minor.—Rare in cult. The name is sometimes used in horticulture for plants which belong under *S. azurea* var. *grandiflora* or *S. splendens* var. *grandiflora*.

4. *ringens*, Sibth. & Smith. Hardy shrub, 1-2 ft. high: sts. glabrous or spreading, pilose at base, viscous-pubescent above: lvs. petiolate, irregularly pinnatisect, the segms. unequal, ovate-oblong, base rotundate, both surfaces villous, scarcely canescent beneath, the petioles long-ciliate; floral lvs. membranaceous, deciduous: raceme simple; floral whorls about 6-fld., lax, remote; calyx nodding, tubular-campanulate, striate, villous-viscous, the teeth rather acute; corolla reddish purple or light blue, the tube recurved-ascending, the throat very broad. Summer. Greece. Gt. 2:226.

Section 2. HYMENOSPACE.

Shrubs or subshrubs, rarely herbs. Oriental and S. African species.

- A. Lvs. ovate-subrotund. 5. *aurea*
 AA. Lvs. hastate-triangular. 6. *canariensis*

5. *aurea*, Linn. Shrub, 3 ft. or more high, white-tomentose: lvs. $\frac{1}{2}$ -1 in. long, petiolate, ovate-subrotund, obtuse, entire or sinuate, leathery, hoary; floral lvs. sessile, villous, persistent: racemes dense, 2-4 in. long, somewhat branched; floral whorls 2-fld., approximate; calyx broad-campanulate, villous, the lips membranous dilated, veined, and colored, the lobes ovate-rotundate; corolla very beautiful, golden yellow, the galea somewhat falcate. July. S. Afr. B.M. 182. G.C. II. 26:745.—Intro. into Calif. According to one grower the fls. are at first sulfur-yellow turning very quickly to a rusty color.

6. *canariensis*, Linn. Shrub, about 6 ft. high: st. shrubby, white-lanate: lvs. petiolate, lanceolate, hastate-triangular, subglabrous; floral lvs. ovate-lanceolate, membranaceous and colored: racemes branched; floral whorls approximate, distinct, about 6-fld.; calyx incurved-campanulate, the lips dilated membranaceous, colored; corolla purplish, the galea somewhat falcate. Canary Isls.—Probably not in common cult.

Section 3. DRYMOSPACE.

Herbs, usually tall and glutinous.

- A. Corolla yellow.
 B. Plant about 3 ft. high: lvs. ovate-oblong. 7. *glutinosa*
 BB. Plant 6-12 in. high: lvs. ovate-trilobed or triangular. 8. *nipponica*
 AA. Corolla blue or purplish.
 B. Raceme simple, spike-like: lvs. purple beneath. 9. *yunnanensis*
 BB. Raceme more or less branched.
 C. Floral whorls 6-fld. 10. *hians*
 CC. Floral whorls about 2-fld. 11. *Przewalskii*

See *S. flava*, G. Forest, in supplementary list, which probably belongs to this section.

7. *glutinosa*, Linn. (*S. nubicola*, Wall.). Perennial, about 3 ft. high: st. herbaceous, erect, glutinous-pilose, divaricately branched: lvs. petiolate, the lowest 7-8 in. long, the upper smaller, ovate-oblong, acuminate, dentate, the base cordate-sagittate; floral lvs.

3535. Types of *Salvia*. At the left *S. carduacea*; unique for its fringed flowers. Next is *S. leucantha*, example of kinds in which the flower does not gape widely. The two at the right, *S. hians* and *S. sessei*, are interesting for the size and lobing of the middle lobe of the lower lip. (All $\times \frac{1}{2}$)

ovate, acuminate: racemes simple; floral whorls distant, laxly few-fld.; calyx tubular; corolla pale yellow, often $1\frac{1}{2}$ in. long, the tube exserted with its throat broadened. July. Eu. and Asia.

8. *nippōnica*, Miq. Herb, 6-12 in. high, slightly branched: sts. ascending-erect: lvs. petiolate, opposite, ovate-trilobed or triangular from a truncate cordate-hastate base, the basal lobes horizontal-spreading, the midlobe ovate, larger or equal, all short-acuminate, dentate-crenate, sparsely hirtellus-pubescent above and especially so on the nerves beneath; cauline lvs. 1-3 $\frac{1}{2}$ in. long; floral lvs. ovate, entire: racemes rather lax, 2-4 in. long; floral whorls frequently 4-fld.; calyx obconic- or subcampanulate-tubular, pilose, glandular-punctate; corolla whitish glandular, punctulate when dry, tube half exserted. Japan.

9. *yunnanensis*, C. H. Wright. Perennial herb, about 1 ft. high: rhizomes creeping, bearing fusiform tubers: lvs. $1\frac{1}{2}$ -3 $\times$ $\frac{3}{4}$ -1 in., the radical frequently very long and slender-petioled, oblong, crenate, green above, purple beneath: spikes simple; floral whorls 4-6-fld.; calyx glandular; corolla cobalt-blue, 1 in. long, pubescent outside. China.

10. *hians*, Royle (*S. himalayaca*, Hort.). Fig. 3535. Hardy perennial, about 2 ft. high: st. herbaceous, erect, villous: lvs. long-petiolate, ovate, base broadly cordate-sagittate or truncate; floral lvs. ovate, acuminate: racemes somewhat branched; floral whorls 6-fld.; calyx campanulate, striate, bluish, glutinous; corolla

showy, blue, tube exserted, broad, the limb short, gaping, the upper lip falcate. June. Cashmere. B.M. 6517. B.R. 27:39. R.H. 1845:145. Gt. 35:1221. Var. *plectranthifolia*, Paxt., has fls. which are rather smaller, less hairy and deeper violet than the type.

11. *Przewalskii*, Maxim. Sts. ascending, 3–5 ft. high, herbaceous, pubescent, glandular above: radical lvs. long-petioled, crenate-dentate, hoary-tomentose beneath, acute, cordate-oblong; cauline lvs. acute, hastate-cordate; floral lvs. ovate, acute: racemes composite, spike-like; floral whorls distant, about 2-fld.; calyx campanulate, striate, glandular, the teeth acute, short-triangular; corolla violet, the tube long-exserted. June. China.

Subgenus II. SCLAREA.

All Old-World, herbaceous species.

Section 4. HORMINUM.

Annual herbs.

12. Horminum

12. *Horminum*, Linn. Annual, about 1½ ft. high: st. herbaceous, erect, villous: lvs. petiolate, oval-oblong, base rotund or cuneate, obtuse, crenate, villous; floral lvs. very broad, acute, persistent, the upper ones variously colored: racemes simple; floral whorls distant, about 6-fld.; calyx tubular, pubescent; corolla light lilac or pale violet to reddish violet or purple. June–Aug. S. Eu. Var. *alba*, Hort., has white floral lvs. Var. *purpurea*, Hort., misspelled *purpureum* (S. *Horminum* var. *rubra*, Hort.), has bright carmine-red to brilliant purple-red floral lvs. darker veined. Var. *violacea*, Hort. (S. *Bluebeard*, Hort.), has light violet-blue floral lvs. somewhat larger and darker veined. Var. *vulgaris*, Hort., has violet-blue floral lvs., with darker veins.

Section 5. ÆTHIOPIS.

- A. Lvs. or lobes of the lvs. oblong-lanceolate or linear.....17. *Montbretii*
- AA. Lvs. or lobes of the lvs. broad-ovate.
 - B. The lvs. hoary-tomentose.....13. *Sclarea*
 - BB. The lvs. green, the white wool lax.
 - C. Floral lvs. all floriferous.....14. *æthiopis*
 - CC. Floral lvs., the uppermost, sterile.
 - D. Plant about 2 ft. high: panicle strongly branched.....15. *argentea*
 - DD. Plant scarcely 1 ft. high: panicle slightly branched.....16. *verbascifolia*

13. *Sclarea*, Linn. (S. *bracteata*, Sims, not Soland., in Russ. S. *Simsiana*, R. & S.). CLARY. Biennial, 2–3 ft. high: st. herbaceous, stout, erect, villous: lvs. often 8–9 x 4–5 in., petiolate, broad-ovate, erose-crenate, base cordate, hoary, the uppermost clasping; floral lvs. very broad, acuminate, concave, membranaceous, colored, their base white, their tips rose: racemes paniculate; floral whorls distant, about 6-fld.; calyx campanulate, striate, pubescent-hispid, the teeth rather spiny-acuminate; corolla whitish blue, the tube included. Aug. S. Eu. B.M. 2320. B.R. 1003. G.C. III. 44:268. Gn. 64, p. 249. G.M. 57:173. Var. *turkestanica*, Hort. (S. *turkestanica*, Hort. S. *turkestaniana*, Hort.), grows 3 ft. high, has quadrangular sts. tinged with pink, basal lvs. on long petioles and long spikes, 2½ ft. high, of large white fls., tinged with pink. There is a form offered in the trade under the name of S. *turkestanica superba*, Hort., which has "dense branched pyramids of silky foliage and conspicuous rosy bracts, and white fls." S. *bracteata*, Soland., in Russ., is a valid species belonging to Section 1. It is a subshrub about 1–1½ ft. high, with purplish fls. and a native of Asia Minor and Syria. Probably not in cult.

14. *æthiopis*, Linn. Perennial, 6–12 in. or more high: st. herbaceous, erect, white-lanate: lower lvs. petiolate, narrow at base; cauline lvs. cordate-clasping; all incise-dentate, densely white-lanate on both sur-

faces; floral lvs. very broad, acuminate, persistent, concave, lanate: racemes paniculate; floral whorls distinct, 6–10-fld.; calyx campanulate, leathery, lanate, plicate-striate, the teeth all subulate-spinose; corolla white, the upper lip often reddish, tube contracted at the middle; connectives not toothed. S. Eu., N. Afr., and the Orient.—Probably not common in cult. S. *æthiopis*, Brot., not Linn., equals S. *argentea*, which see.

15. *argentea*, Linn. (S. *pátula*, Desf.). Biennial, 2–4 ft. high: sts. herbaceous, erect, villous: lvs. radical and lower cauline, 6–8 x 4–6 in., broad-ovate, sinuate-lobate, the lobes erose-crenate, lanate; floral lvs. very broad, acuminate, concave, persistent: panicles divaricate-branched; floral whorls remote, 6–10-fld., the uppermost abortive; calyx campanulate, striate, the teeth all subspinose; corolla showy, rose-white, whitish, purplish or yellowish, the galea or upper lip much longer than the lower. June. Medit. region of Eu. and Afr. F.C. 3:112. Gn. 73, p. 517.—For some reason this species is considered a hardy perennial by American seedsmen. The foliage is white-woolly, making it a very decorative plant.

16. *verbascifolia*, Bieb. (S. *microstègia*, Boiss. & Bal.). Perennial: st. herbaceous, erect, viscous-villous: lower lvs. petiolate, broadly ovate, base cordate, sinuate-lobate, erose, thick, very wrinkled, scarcely lanate above, white tomentose-lanate beneath; floral lvs. very broad, acuminate, concave, persistent, villous: panicles twiggy branched; floral whorls 2–6-fld., approximate, distinct, the uppermost abortive; calyx campanulate, striate, viscous-villous; corolla white, beset with blue hairs, galea very large and falcate. Caucasus region. Var. *kurdica*, Hort., is offered in the trade.

17. *Montbretii*, Benth. Perennial subshrub, low: sts. erect, the base white-lanate, the top viscous-villous: lvs. lanceolate, the lower petiolate, the upper clasping, crenulate or obscurely pinnatifid-dentate, laxly white-lanate above, densely so beneath; floral lvs. very broad, lanate beneath: racemes simple; floral whorls 6–10-fld.; calyx oblong-tubular, viscous-pubescent; corolla blue. Asia Minor and Syria.

Section 6. PLETHIOSPACE.

- A. Corolla 1 in. or more long.
 - B. Pedicels longer than the calyx.
 - C. Lower lvs. incise-palmatifid.....18. *bicolor*
 - CC. Lower lvs. oblong-ovate or ovate-lanceolate, sinuate-serrate.....19. *dichroa*
 - BB. Pedicels shorter than the calyx.
 - C. Sts. subsimple, 1–3 ft. high.....20. *pratensis*
 - CC. Sts. 4–6 ft. high: panicles branched, very large.....21. *virgata*
- AA. Corolla ½ in. or less long, rarely as much as ¾ in.
 - B. Lvs. incise-pinnatifid.....26. *controversa*
 - BB. Lvs. entire, crenate or erose-dentate.
 - C. Racemes erect and strict.
 - D. The lvs. all oblong-lanceolate or narrowly oblong.
 - E. Under surface of lvs. canescent.....22. *sylvestris*

3536. *Salvia pratensis*. (×¼)

- EE. *Under surface of lvs. pubescent but not canescent*. 23. *memorosa*
 DD. *The lvs., at least the lower ones, broad-ovate or ovate-oblong.*
 E. *Plant scarcely 2 ft. high; corolla scarcely 1/2 in. long*. 25. *Verbenaca*
 EE. *Plant 4-6 ft. high; corolla usually about 3/4 in. long*. 21. *virgata*
 CC. *Racemes nodding at the top*. 24. *nutans*

18. *bicolor*, Lam. Biennial, sometimes perennial (?), hardy: sts. herbaceous, erect, 2-3 ft. high, scarcely branched: lvs., the lowest petiolate, broad-ovate, incise-dentate, pinnatifid or palmate-lobate; the upper sessile, lanceolate, all cordate at base and glutinose-pubescent; floral lvs. ovate-lanceolate, acuminate, reflexed: racemes 1½-2 ft. long, many-flid.; floral whorls distinct, about 6-flid.; calyx campanulate, striate, glutinose-hispid, the teeth subulate-acuminate; upper lip of corolla hooded, bluish violet dotted with yellow, the lower one white, but said to fade quickly to a rusty brown. May-July. Spain and N. Afr. B.M. 1774. G.M. 40:487. P.M. 9:271.

19. *dichroa*, Hook. f. Half-hardy perennial: sts. 2-3 ft. or more high, quadrangular with obtuse thickened yellowish angles, which are retrorsely ciliate: radical lvs. petioled, 6-8 in. long, oblong-ovate or ovate-lanceolate, obtusely and very irregularly sinuate-serrate, pubescent; upper cauline lvs. sessile-oblong or elliptic-oblong; floral lvs. ovate, long-acuminate, reflexed: raceme 1 ft. or more long, many-flid.; floral whorls 2-3-flid.; calyx subcampanulate, glandular-pubescent, strongly ribbed, green; corolla 1-1½ in. long, upper lip bright blue, arcuate, pubescent, lower lip 3-lobed, the lateral lobes pale blue, the midlobe orbicular, pendulous, white. Aug. Atlas Mts. of N. Afr. B.M. 6004. G.C. III. 40:177. Gn. 72, p. 78.—By some authorities this is considered the same as *S. bicolor*.

20. *pratensis*, Linn. Fig. 3536. Hardy perennial, 2 ft. or more high: root sometimes pubescent: sts. herbaceous, erect, subsimple, pubescent: lvs., especially in the southern varieties, more or less blood-red maculate; radical lvs. petiolate, oblong-ovate, obtuse, crenate or incised, base cordate, bullate-rugose, glabrous above, pubescent beneath along the petiole and nerves; cauline lvs. few, sessile; floral lvs. cordate-ovate: racemes viscous, subsimple; floral whorls 6-flid., distant; calyx subsessile, campanulate, viscous-villous; corolla bright blue, rarely reddish or white, large, 1 in. long. June-Aug. Eu. Var. *alba*, Hort., has pure white fls. Var. *albiflora*, Hort., is a white-flid. form; perhaps this and the preceding are the same. Var. *atroviolacea*, Hort., has dark violet fls. Var. *Baumgartenii*, Hort. (*S. Baumgartenii*, Heuff.), has violet fls. Var. *lupinoides*, Hort. (*S. lupinoides*, Hort.), is said to grow 2 ft. high and to have bluish purple and white fls. Var. *rosea*, Hort. (*S. salvatiori*, Hort.), has rosy purple fls. Var. *rubicunda*, Hort. (*S. rubicunda*, Wender.), has rose-red fls. Var. *superba*, Hort., is offered in the trade. Var. *Tenorii*, Hort. (*S. Tenorii*, Spreng.), is said to grow 2 ft. high and to have deep blue fls. Var. *variegata*, Hort. (*S. variegata*, Walst. & Kit.), has light blue fls. with the midlobe of the lower lip white.

21. *virgata*, Ait. (*S. gigantea*, Desf.). Hardy perennial, 2 ft. or more high: sts. herbaceous, erect, branched, pubescent-villous: radical lvs. petiolate, broad-ovate, base cordate; lower cauline lvs. short-petioled, broad ovate-oblong, base rotund or cordate, upper ones sessile and smaller, the uppermost cordate, clasping; all the lvs. erose-crenate, rather glabrous above, pubescent or hispid on the nerves beneath; floral lvs. ovate-acuminate somewhat reflexed: racemes branched, elongated, few-flid.; floral whorls 6-flid., distant; calyx short-pedicelled, campanulate, striate, villous-viscous; corolla light blue, the tube included. S. E. Eu. and the Orient. Var. *alba*, Hort., a white form, is offered in the trade.

22. *sylvestris*, Linn. Hardy perennial, 6 in. to 3 ft. high: sts. herbaceous, paniculate above: lvs. often small, scarcely 2 in., sometimes 3-4 in. or more long, the lower petiolate, the upper sessile, all oblong-lanceolate, crenate, base rounded or frequently cordate, glabrous above, paler, pubescent or canescent beneath; floral lvs. orbiculate, acuminate, colored: racemes elongated, somewhat branched; floral whorls 6-10-flid., distinct; calyx ovate-tubular; corolla purple-violet. Aug. Eu. and Asia. Var. *alba*, Hort. (*S. sylvestris* var. *flore-albo*, Hort.), is a white-flid. form.

23. *memorosa*, Crantz (*S. virgata*, Hort., not Ait. *S. virgata memorosa*, Hort.). Fig. 3537. Perennial, 2-3 ft. high, much branched: radical lvs. short-petioled, cauline sessile, lanceolate, 2½-3 in. long, the upper lvs. gradually reduced in size, glabrous and dull green above, pale and finely pubescent beneath: fls. small, in very long slender spikes terminating all the branches, up to 16 in. long; floral whorls approximate, 6-flid.; corolla bright violet or purple. June-Oct. Eu. and W. Asia. G.M. 56:714. R.H. 1913, p. 471.—The fls. are sometimes described as being bronzy purple. Var. *alba*, Hort., is said to grow 18 in. high and to have short spikes of white fls. This may be the same as *S. sylvestris* var. *alba*, as *S. memorosa*, Linn., is a synonym of *S. sylvestris*.

24. *nutans*, Linn. Hardy perennial, 2-3 ft. high: sts. herbaceous, subsimple, pubescent to nearly naked: lvs. few, the lower long-petioled, ovate-oblong, 4-5 in. long, double-crenate, the base subcordate; floral lvs. minute, orbicular: racemes short, 1-1½ in. long, paniculate, long-peduncled, nodding after anthesis; floral whorls about 6-flid., approximate; calyx reflexed, pubescent; corolla violet, the galea straight and spreading. July. S. E. Eu. B.M. 2436.

25. *Verbenaca*, Linn., also spelled *verbenacea*. (*S. Spielmanni*, Willd.). Hardy perennial, 1-2 ft. high: sts. herbaceous, erect, pubescent or villous: lvs. often 3-4 in. long, broad-ovate or oblong, crenate, glabrous; the lower long-petioled, base narrowed; the upper broader, sessile, base cordate, floral lvs. ovate-rotund, acuminate, villous, persistent: racemes elongated, simple or somewhat branched; floral whorls remote, about 6-flid.; calyx ovate, hirsute; corolla blue, rarely white, galea straight or somewhat falcate. June-Sept. Eu. and Orient. Var. *clandestina*, Briquet (*S. clandestina*, Linn.), is a smaller and more slender form than the type, with narrower lvs. and more purple fls. and the upper lip of the corolla is longer arched. Eu.—*S. spelmina*, Hort., is a name appearing in American trade-lists for a plant which grows 2 ft. high and with deep blue fls. in July. Presumably an error for *Spielmanni*.

3537. *Salvia nemorosa*. (X 1/6)

26. *controversa*, Ten. St. herbaceous, pubescent or villous: lvs. oblong, incisely pinnatifid, the lobes oblong-linear, very obtuse, incise-crenate, bullate-rugose, the margin revolute, both surfaces somewhat pilose; floral lvs. ovate-rotundate acuminate: racemes branched, long, white-villous; floral whorls 6-10-flid., the lower remote, the upper approximate; calyx ovate, very long

hirsute-lanate, the teeth minute; corolla small, sometimes minute. *Medit. region.*—Not common in cult.

Subgenus III. JUNGIA.

All American species.

Section 7. CALOSPHERE.

Herbs, subshrubs or shrubs.

- A. *Lvs. rugose: corolla-tube slightly exerted, straight, ventricose or broadened above, the lips subequal or the upper longer.*

Subsection ERIANTHÆ.

(See also Nos. 36, 39, 43 and 44.)

31. *leucantha*
AA. *Lvs. seldom rugose (rugose in Nos. 36, 39, 43, and 44).*
B. *Corolla about ½ in., occasionally a little longer.*

Subsection BRACHYANTHÆ.

II. *Lower surface of lf. glabrous.*.....38. *involutrata*
37. *gesneræflora*

Subsection BRACHYANTHÆ.

27. *azûrea*, Lam. (*S. acuminata*, Michx., not Cav.). Perennial, 1–6 ft. high: sts. herbaceous, erect, glabrous: lvs. petiolate, oblong-lanceolate or linear, rather obtuse or acute, base long-narrowed, somewhat serrate, both surfaces green and glabrous; floral lvs. lanceolate-linear, deciduous: racemes simple, elongated; floral whorls distant, about 6-fld.; calyx green or bluish, subsessile, tubular, striate, the 3 teeth broad, rather acute; corolla blue. Aug. S. C. to Fla. and Texas. B.M. 1728. Var. *grandiflora*, Benth. (*S. Pitcheri*, Torr.), which differs in being cinereous-puberulent, in its denser infl. and tomentulose-sericeous calyx. G.C. II. 14:685. Gn. 19:600; 61, p. 309. G.Z. 26:121.—Probably the plant formerly offered as *S. Pitcheri* var. *angustifolia*, Hort., belongs here. It is quite probable that some of the material in the trade as *S. azurea* var. *grandiflora* is in reality *S. farinacea*. Var. *grandiflora alba*, Hort. (*S. azurea* var. *alba grandiflora*, Hort.), is a white-fld. form of the variety.

28. *farinacea*, Benth. Perennial, 2–3 ft. high: st. herbaceous, erect, tomentose: lvs. petiolate, ovate-oblong, or lanceolate, rather obtuse, irregularly serrate-crenate, rather glabrous, both surfaces green or the lower canescent; floral lvs. small, deciduous: racemes elongated, simple; floral whorls many-fld., subsecund, remote or the uppermost approximate; calyx subsessile, tubular, purplish colored, densely white-lanate; corolla purple or violet, the tube scarcely exerted. Summer. Texas, where it is reported as growing in rich soil. Gn. 9:430; 28, p. 59; 78, p. 226. R.H. 1873:90.—A showy frequently cultivated species, the fls. quite attractive, the darker corollas being set off by the mealy lighter violet-white calices. Var. *alba*, Hort., is a white-fld. form with the midlobe of the lower corolla-lip obovate, 2-lobed.

29. *uliginosa*, Benth. Sts. herbaceous, erect, 2–6 ft. high, virgate, branched, glabrous or villous: lvs. 2–4 in. long, petiolate, oblong-lanceolate, acute, serrate, base narrowed, glabrous or pubescent; floral lvs. membranaceous, broad-ovate, acuminate, deciduous: racemes dense, long-peduncled, somewhat branched; floral whorls many-fld.; calyx campanulate, variable, sometimes colored; corolla blue or white, tube somewhat or nearly included. Brazil, Argentina, and Uruguay. B.M. 8544. Gn. 77, p. 484. G.M. 56:711. R.H. 1912, p. 469.

30. *amarissima*, Ort. Perennial, about 2 ft. high: sts. herbaceous, erect, branched, pilose-hispid: lvs. petiolate, ovate-cordate, crenate, canescent below; floral lvs. ovate, acuminate, deciduous: racemes simple, densely fld.; floral whorls distinct, subremote, about 10-fld.; calyx tubular-campanulate, striate-villous, the 3 teeth rather acute; corolla blue. Aug. Mex. B.R. 347.—Probably rare in cult.

Subsection ERIANTHÆ.

31. *leucantha*, Cav. Fig. 3535. Shrub, about 1½–2 ft. high: st. shrubby, with elongated branches which are subterete, and white-lanate, the wool finally caducous: lvs. short-petioled, lanceolate-linear, acute, crenate, base rotundate, pubescent and rugose above, white-lanate beneath; floral lvs. ovate, acuminate, deciduous: raceme elongated, often purplish, 6–10 in. long; floral whorls many-fld., the lower remote; calyx subsessile, ovate, densely lavender- or violet-lanate; corolla white, white-lanate outside. June. Mex. B.M. 4318. Gn. 21:328.—Probably not very common in cultivation, at least in N. Amer.

Subsection LONGIFLORÆ.

Nobiles.

32. *splendens*, Ker-Gawl. (*S. colorans*, Hort. *S. brasiliensis*, Spreng.). SCARLET SAGE. Figs. 3538, 3539. Tender shrub or subshrub, treated as an annual, about 3 ft. high: st. shrubby with glabrous branches: lvs. petiolate, ovate, acuminate, crenate-serrate, base cuneate, rotundate or cordate, both surfaces glabrous; floral lvs. ovate, acuminate, colored: racemes terminal, spikelike, 6 in. or more long; floral whorls about 2-fld. (2- rarely 6-fld.), about 30 fls. in a raceme; calyx campanulate, membranaceous, scarlet, glabrous or villous, teeth 3, broad-ovate, acute; corolla scarlet, glabrous. Autumn. Brazil. B. R. 687. L.B.C. 11:1089. Var. *alba*, Hort., has creamy white fls. Var. *atropurpurea*, Hort., a form with dark violet-purple fls. Var. *atrosanguinea*, Hort., has deep crimson fls. Var. *bicolor*, Hort., with large spikes of scarlet-and-white fls. Var. *Bruanti*, Hort., dwarfer than the type in habit and brighter scarlet fls. G.C. II. 14:781; III. 6:653. Gn. 21:328 (good). A. F. 5:331. Var. *compacta*, Hort., dwarfer habit, racemes thicker and more numerous, fls. brilliant scarlet. Var. *compacta alba*, Hort., a whitish variant of the preceding variety. Var. *compacta erecta*, Hort., a dwarf form with dark scarlet fls. Var. *grandiflora*, Hort., is a tall-growing large-fld. form. G.M. 43:853. R.B. 27:12. The following variants of this variety are offered: Var. *grandiflora erecta*, Hort. Var. *grandiflora nana*, Hort. Var. *grandiflora pendula*, Hort. Var. *grandiflora prostrata*, Hort. Var. *Issanchon*, Hort. (*S. brasiliensis* var. *Issanchon*, Hort.), has the calyx white, striped red and a rose-white corolla, habit similar to var. *compacta*. Var. *nana*, Hort., is a dwarf form, rather early flowering, the fls. bright red. Var. *purpurea*, Hort., is offered in the trade. Var. *pyramidalis*, Hort., is offered in the trade. F.E. 31:325. Var. *roseo-carminea*, Hort., is offered in the trade. Var. *semperflorens*, Hort., is characterized as an early and continuous-flowering form. Var. *Souchetii*, Planch. (*S. Souchetii*, Hort.), is probably the same as var. *compacta*. There is a white-fld. variant of this variety known in the trade as *S. Souchetii* var. *alba*, Hort. Var. *violacea*, Hort., is

3538. *Salvia splendens*. ($\times \frac{1}{2}$)

offered in the trade.—*S. nana*, HBK., is a valid species belonging to Section 7. It is herbaceous, with a perpendicular, thickened tuberous root, almost stemless, with subsessile radical lvs. forming a rosette, and blue fls. Mex. Probably not in cult.

Inflatæ.

33. *Sessei*, Benth. (*S. Roëzii*, Scheidw.). Fig. 3535. Subshrub, about 1½ ft. high: sts. shrubby with rather glabrous branches: lvs. 2-3 in. long, somewhat leathery, petiolate, broad-ovate or ovate-oblong, acuminate, base rounded cuneate or narrow, both surfaces glabrous or pubescent; floral lvs. smaller, the uppermost minute, deciduous: panicle short, lax; floral whorls few-fld.; calyx inflated-campanulate, scarlet, glabrous; corolla scarlet, almost 2 in. long, pubescent. Summer. Mex. F.S. 14:1407.

Fulgentes.

34. *Grahamii*, Benth. Shrub, 2-3 ft. high: st. shrubby with glabrous or very slightly pubescent branches: lvs. petiolate, oval, obtuse, base rounded or cuneate, irregularly crenate in the center, subglabrous; floral lvs. ovate, acuminate, ciliate, deciduous: racemes elongated, more than 1 ft. long; floral whorls 2-fld.; calyx tubular, striate-nerved, pubescent, frequently colored; corolla deep crimson or when older purple, the midlobe of the lower lip, which is large and obcordate, has two small white spots. Summer. Mex. B.R. 1370. L.B.C. 18:1798. G.W. 15, p. 48.

35. *Grëggii*, Gray. Shrub, 1-3 ft. high: sts. glabrous or obscurely farinaceous; the branches slender: lvs. coriaceous, 1-ribbed, almost veinless, oblong, entire, base narrowed to a short petiole: racemes 2-3 in. long, 6-8 fld.; calyx narrowly campanulate, slightly pubescent or glandular; corolla red or purplish red, about 1 in. long, the tube strongly ventricose-gibbous, the throat abruptly contracted, the lower lip large and showy. Autumn. Texas and Mex. B.M. 6812. Var. *alba*, Hort., is a white-fld. form.

36. *fulgens*, Cav. (*S. cardinalis*, HBK.). CARDINAL SALVIA. MEXICAN RED SALVIA. Perennial shrub, 2-3 ft. high: the numerous branches almost glabrous or pilose-hirsute: lvs. petiolate, 1-3 in. long, ovate, acute, crenate-serrate, base cordate, pubescent above, white-tomentose or lanate beneath; floral lvs. sessile, ovate, deciduous: racemes 6-12 in. long; floral whorls 6-fld., rather distant; calyx pedicelled, tubular-campanulate, pubescent, corolla showy scarlet, about 2 in. long, villous. July. Mex. B.R. 1356. L.B.C. 20:1910.—The fls. are darker red than those of *S. splendens* and the calyx is said to be dull colored and conspicuously striate. Apparently not very frequently cult. Var. *Boucheana*, Benth. (*S. Boucheana*, Kunth), has the lvs. narrowly deltoid-ovate, truncate or subcordate at the base. Mex.

37. *gesneræiflora*, Lindl. & Paxt. (*S. gesneriæfolia*, Lem.). Perennial herb about 2 ft. high (possibly sometimes a subshrub): the branches numerous and glandular-pilose: lvs. ovate-cordate, short-acuminate, crenulate-dentate, puberulent-ciliate and rugose-plicate above, densely long-pubescent-canescens beneath: floral whorls 5-6-fld., with very short pedicels; calyx green, tubular-dilated; corolla scarlet, 2 in. or more long, the tube globose-inflated, throat slightly constricted, short-pubescent. Said to flower in April and again in Nov. Colombia. F.S. 20:2131. I.H. 1:32. J.F. 2:179. J.H. III. 48:191.—Considered by many to be only a variety or form of *S. fulgens* which it closely resembles.

38. *involutrâta*, Cav. Half-hardy subshrub, several feet high: sts. shrubby; the branches elongated: lvs. petiolate, 2-3 in. long, ovate, acuminate, crenate-serrate at the middle, the base rotund-cuneate, glabrous; floral lvs. bract-like, sessile, broad-ovate, acuminate, colored, deciduous after anthesis: racemes spicate, in fl. subglobose, at length 4-6 in. long; floral whorls about 6-fld., approximate; calyx tubular-campanulate, striate, viscous, often colored, the teeth setaceous-acuminate; corolla rose, tube ventricose, generally long-exserted, sometimes short, galea villous. Aug. Mex. and Cent. Amer. B.M. 2872. B.R. 1205. R.H. 1858, p. 239. H.F. II. 2:204.—The floral lvs. are large, showy, and rather a rose-purple, the fls. frequently shading toward purple. Var. *Béthellii*, Hort. (*S. Béthellii*, Hort.), is a horticultural form with large, cordate-oval lvs. and bright rosy crimson or puce fls. borne in large terminal whorled spikes. F.M. 1881:464. G.C. II. 15:49. Var. *Deschampsiana*, Verl., grows 3 ft. or more high: lvs. cordate-acuminate: fls. in ovate spicate terminal clusters: bracts ovate, caducous, they and the calyx bright red; corolla bright rose. French garden origin. R.H. 1869:134, desc.

Cyanææ.

39. *álbo-cærulea*, Lind. Subshrub, about 3 ft. high: sts. erect: lvs. petiolate, oblong-lanceolate, long-acuminate, 4-6 in. long, crenate-serrate, decurrent into the petiole, nearly glabrous above, softly pubescent beneath: racemes simple, 6-12 in. long; floral whorls 4- to many-fld.; calyx green, campanulate-tubular, glandular-pubescent; corolla-tube and upper lip cream-colored, lower lip rich indigo-blue sometimes tinged with violet or purple. Summer. Mex. F.S. 13:1340. Gt. 7:96.—Rare in cult.

40. *iánthina*, Otto & Dietr. (*S. Hoveyi*, Hort.). Perennial, about 2 ft. high: sts. herbaceous, erect, puberulous: lvs. ovate-subcordate, acuminate, crenate, rugose, paler beneath; floral lvs. ovate, acuminate, colored: infl. terminal; floral whorls 6-fld., clustered; corolla large, intense purple-violet. June. Habitat uncertain, probably Mex. or Peru. F.S. 9:884. R.H. 1854:61. G.C. II. 15:145.

41. *cyânea*, Benth. St. shrubby: branches 4-angled, hoary-pubescent or glabrous: lvs. petiolate, ovate, acuminate, serrate-crenate, pubescent, or frequently canescent beneath; floral lvs. ovate, acuminate, membranaceous, deciduous: racemes simple; floral whorls laxly 6-10-fld., subsecund; calyx tubular, bluish, glandular-villous; corolla blue, the tube exserted and ventricose. Mex. and Cent. Amer.

Tubulifloræ.

42. *Goudôtti*, Benth. (*S. lantanæfolia*, Hort., not Mart. & Gal.). Shrub, about 2 ft. high, with the branches red-puberulent or glabrous: lvs. about 3 in. long, ovate or ovate-lanceolate, acuminate, serrate-crenate, base narrowed, both surfaces pubescent; floral lvs. lanceolate-subulate, deciduous: racemes simple; floral whorls 6-10-fld., subsecund; calyx tubular-campanulate, the teeth ovate, ciliate-margined; corolla red, more than 1 in. long. Colombia. R.B. 25:121.

43. *coccinea*, Linn. (*S. rosea*, Vahl). Annual or sometimes perennial and subshrubby: st. herbaceous, erect, 1-2 ft. high, canescent-pubescent: lvs. petiolate, 1-2 in. long, ovate, acute, crenate, base cordate, pubescent above, hoary-tomentose beneath; floral lvs. ovate, acuminate, deciduous: racemes simple; floral whorls remote, 6-10-fld.; calyx tubular-campanulate, striate, often purplish, the teeth acute; corolla scarlet, glabrous. July. S. C. to Fla. and Texas, Mex., W. Indies, Trop. Amer., and cult. and occasionally escaped in India and Austral.—Probably all of the material grown as this is not true to name, possibly the larger part of it is in reality *S. splendens*. Var. *bicolor*, Hort., has the upper

lip white, the lower lip brilliant carmine-red. Var. *lacteæ*, Hort., has white fls. Var. *mâjor*, Regel (*S. filamentosa*, Tausch. *S. Roemeriana*, Hort., not Scheele), becomes a subshrub up to 4½ ft. high, is apt to be less canescent-pubescent and has larger bright scarlet-red fls. June to late autumn. Gt. 7:232. Var. *nâna*, Hort., is a dwarf much-branched form. Var. *nâna carminea*, Hort., is offered in the trade. Var. *nâna compâcta*, Hort., is a dwarfer and more bushy form than the variety proper.

Var. *pseudo-coccinea*, Gray (*S. pseudo-coccinea*, Jacq.), grows 2-4 ft. high, and has the st., petioles, and often the margins of the floral lvs. conspicuously beset with hirsute hairs. Mex. and Cent. Amer. B.M. 2864.

3539. *Salvia splendens*. No. 32.

J.F. 2:35. Var. *punicea*, Hort. (*S. coccinea* var. *splendens*, Hort. *S. superba*, Hort.), differs from the type in being larger, slenderer and later-flowering and in having fls. of a brighter red, more velvety and more closely placed. Var. *punicea nâna*, Hort., differs from the variety proper in being dwarfer and the twigs more branched. Var. *rosea nâna*, Hort., is offered in the trade. Var. *splendens*, Hort., equals var. *punicea*, Hort.

44. *longistyla*, Benth. (*S. aristulata*, Mart. & Gal.). Plants reaching a height of 14-15 ft.: sts. herbaceous(?), erect, tomentose-villous: lvs. petiolate, broad-ovate, 3-5½ x 2-4½ in., acuminate, crenate, the base broad-cordate, rugose, both surfaces soft pubescent-villous; floral lvs. ovate, long-acuminate, ciliate, deciduous: racemes 15-25 in. long; floral whorls 6-16-fld.; calyx elongate-tubular, base striate, soft-pubescent, the teeth long setaceous-acuminate; corolla red-pink, long-exserted, rather more than 1 in. long. Mex. B.M. 8590.

Hastatæ.

45. *pâdens*, Cav. Half-hardy perennial, 1-2½ ft. high: sts. herbaceous, erect, pilose: lvs. petiolate, ovate-

deltoid, crenate, base hastate or in the upper lvs. rotund, both surfaces hispid; floral lvs. lanceolate-linear: floral whorls few, remote, with large fls.; calyx campanulate, villous, the teeth setaceous-acuminate; corolla blue, 2 in. or more long, the tube broad. Sept. Mountains of Mex. B.M. 3808. B.R. 25:23. B. 3:109. F. 1840:222. F.S. 5:503. P.M. 6:1. R.B. 26:85. R.H. 1909:156. H.U. 1, p. 39.—The most commonly cult. blue salvia. Var. *alba*, Hort., differs only in having white fls. F.S. 5:503. Var. *compacta nana*, Hort., is offered in the trade. Var. *lilacina*, Hort., has lilac-blue fls.

46. *calialisefolia*, Benth. Tender perennial: sts. herbaceous, erect, about 3 ft. high, pubescent: lvs. petiolate, broad-deltoid, the base angulate, broad subhastate-cordate, rather thick, pubescent above, reddish or whitish and soft-villous beneath; floral lvs. small: racemes branched; floral whorls 2-fld.; calyx campanulate, pilose, the teeth aristate-acuminate; corolla deep blue, pubescent, the tube very broad. June. Mex. B.M. 5274. F.S. 22:2318. Gn. 21:328.

Subgenus IV. LEONIA.

Section 8. ECHINOSPACE.

47. *carduacea*, Benth. Fig. 3535. Perennial, 1 ft. or more high: sts. herbaceous, erect, subsimple, white-lanate: lvs. petiolate, pinnatifid, laxly lanate beneath, the lobes ovate, sinuate-dentate, with spiny, acuminate teeth; floral lvs. and bracts imbricate, very spiny: floral whorls remote, densely many-fld.; calyx inflated, lanate; corolla lilac, the midlobe of the lower lip fimbriate. July. Calif. B.M. 4874. G.C. II. 19:56. Gn. 65, p. 365; 70, p. 238. A.G. 25:589.—A unique species on account of its thistle-like foliage.

Section 9. PYCNOSPACE.

48. *columbaria*, Benth. Half-hardy annual: st. erect, slightly branched, 6–12 in. high: lvs. deeply pinnatifid, wrinkled, rather glabrous, the lobes oblong-linear, obtuse, erose-dentate or incised; floral lvs. bract-like: floral whorls solitary or 2, capitate, far remote from the cauline lvs., densely many-fld., hemispherical; bracts broad-ovate, membranaceous, acuminate; calyx ovate, pubescent; corolla blue, the midlobe of the lower lip crenulate. Summer. Calif. and adjacent Mex. B.M. 6595 (fls. lilac).—Not showy and apparently not in common cult.

Section 10. HETEROSPACE.

- A. *Lvs. lyrata*.....49. *lyrata*
 AA. *Lvs. pinnatifid, they or the terminal lft.*
 roundish or reniform-cordate.....50. *Roemeriana*

49. *lyrata*, Linn. Hardy perennial with a thickened root: sts. herbaceous, erect, 8–24 in. high, subsimple, pilose: radical lvs. 2–3 in. long, lyrate, erose-dentate, both surfaces hispidulous; cauline lvs. few, oblong-lanceolate, the base long-narrowed; floral lvs. oblong-linear: racemes subsimple, interrupted; floral whorls 6-fld., lax, distant; calyx tubular-campanulate, nodding, pilose; corolla blue-purple, about 1 in. long. May and June. Conn. to Ill., south to Fla. and Texas.—Not frequent in cult.

50. *Roemeriana*, Scheele (*S. porphyrantha*, Decne. *S. porphyrata*, Hook.). Perennial, 1–2 ft. high: sts. sparsely long, spreading, hirsute: lvs. or terminal lft. roundish or reniform-cordate, coarsely repand-toothed or crenately incised; lower lvs. usually with 2 or 3 similar but smaller (subsessile or slender-petiolulate) lfts.; floral lvs. mostly shorter than the pedicels: raceme loose and elongated; floral whorls few-fld.; calyx somewhat pubescent; corolla deep scarlet, puberulent, about 1 in. or more long, tubular-funnelform. July. Texas and Mex. B.M. 4939. F.S. 11:1080. R.H. 1854:301.

Section 11. NOTIOSPACE.

51. *japonica*, Thunb. Perennial subshrub, about 1½ ft. high: sts. herbaceous, erect, branched, glabrous: lvs. 3–4 in. or more long, petiolate, pinnatisect, the segms. ovate, acuminate, the base narrowed, incised-dentate or pinnatifid, glabrous; floral lvs. lanceolate: racemes 4–5 in. long, many-fld., subsimple; floral whorls distinct, about 6-fld.; calyx tubular-campanulate, glabrous, striate; corolla dark lilac or blue(?), the tube scarcely exerted. Japan. Var. *alba*, Hort., is a white-fld. form.

Section 12. HEMISPACE.

52. *verticillata*, Linn. Perennial, 2–3 ft. high: sts. herbaceous, erect, pilose-hispid: lvs., the base cordate, lyrate, the uppermost lobe the largest, ovate-rotund or entire, sinuate-crenate, both surfaces hispid or lanate; floral lvs. deflexed and bract-like: racemes branched, often a foot or more long; floral whorls 20–40-fld., remote; calyx villous, corolla lilac-blue, the tube included. July and Aug. Eu., Asia Minor and Caucasus region.

The following species have been in cult. or are not sufficiently known to be classified: *S. amana*, Sims.—*S. lamiifolia*.—*S. angustifolia*, Cav. (Sec. 7). Perennial herb, about 2 ft. high, with subsessile oblong-linear lvs.; calyx often bluish; corolla blue. Mex. B.R. 1554.—*S. arborea*, Hort., is offered in the American trade, as like the scarlet sage, but growing in a tree-like form. Possibly only a variant of *S. splendens*.—*S. asperata*, Falc. (Sec. 5). Stout herb, about 2 ft. high, with broad subcordate-ovate lvs.: corolla yellowish white. Himalaya. B.M. 4884.—*S. austriaca*, Linn. (Sec. 6). Perennial herb, about 2–3 ft. high, with broad-ovate lvs.; corolla yellowish, the upper lip spotted red. S. Eu. B.R. 1019.—*S. boliviana*, Planch. (Sec. 7). Subshrub about 4 ft. high, with ovate-cordate lvs.; calyx dull purple or green and purple; corolla bright scarlet, 3 in. long. Bolivia. B.M. 6714. P.S. 11:1148.—*S. Cameronii*, Regel (Sec. 7). Subshrub, 3–5 ft. high, with ovate or cordate-ovate lvs.; corolla brownish purple, 1 in. long. Probably Mex. Gt. 4:180. Considered by some as probably the same as *S. elegans*.—*S. comphorata*, Hort., is offered in the trade.—*S. candidissima*, Vahl (*S. odorata*, Willd.) (Sec. 5). Subshrub or herb, about 3 ft. high, with ovate, lanceolate or orbicular lvs.: corolla white. Orient.—*S. canescens*, Mey. (Sec. 5). Sts. herbaceous, 2 ft. high, white-lanate at base: lvs. lanceolate-oblong, entire or sinuate-lobate: corolla purple. Caucasus. B.R. 24:36.—*S. Celsiana*, Hort. Shrubby, with dark bronze-green foliage: corolla reddish violet. Hardy in S.W. England and Ireland. Botanically unknown.—*S. ceratophylla*, Linn. (Sec. 5). Sts. herbaceous, white-lanate at base: lvs. deeply pinnatifid, 7–8 in. long, with linear lobes, both surfaces lanate: corolla about 1 in. long, yellowish white. Orient and Asia Minor. F.C. 1:5.—*S. chamaedryoides*, Cav. (Sec. 7). Subshrub about 1 ft. high, with ovate-oblong lvs. which are hoary-tomentose beneath: calyx often purplish; corolla blue, the lower lip very broad. Mex. B.M. 808. L.B.C. 6:576.—*S. confertiflora*, Pohl (Sec. 7). Subshrub, about 3 ft. high, with ovate-oblong lvs., base cuneate: racemes elongated, up to 2 ft.; floral whorls numerous, many-fld.; calyx reddish; corolla small, not gaping, reddish inside, yellowish or reddish outside, covered with yellow wool. Brazil. B.M. 3899. H.U. 3, p. 203.—*S. confusa*, Benth. (*S. interrupta*, Hort., not Schousb.) (Sec. 1). Hardy shrub, about 4 ft. high, with tomentose-pubescent branches: lvs. interrupted pinnatisect, white-lanate beneath: calyx colored, striate and pubescent; corolla whitish. S. Eu.—*S. discolor*, HBK. (*S. mexicana* minor, Hort.) (Sec. 7). Shrub, 2–3 ft. or more high, with ovate-lanceolate lvs.: spikes 8–9 in. long; calyx striate; corolla shining violet. Mountains of Peru. B.M. 6772. G.C. II. 19:341.—*S. elegans*, Vahl (Sec. 7). Perennial herb, 3–4 ft. high with ovate acuminate serrate lvs. hispidulous pubescent or tomentose above, glabrous beneath: corolla blood-red, more than 1 in. long. Mex. and Guatemala. B.M. 6448.—*S. eribocalyx*, Bert. (Sec. 7). Shrub with divaricate hoary-pubescent branches: lvs. oblong-lanceolate: racemes simple and short: calyx densely lanate, frequently reddish; corolla white. Japan. R.H. 1844:1.—*S. fava*, G. Forest. Plant, 8–20 in. high: sts. ascending, erect, more or less pilose above: basal lvs. long-petiolate, 1¼–6½ x 1–3¼ in., hastate-triangular or hastate-ovate, more or less pilose on both surfaces, crenate, double crenate, or crenate-serrate: racemes composite; floral whorls 4–8, subremote, generally 4-fld.; calyx pilose; corolla canary-yellow with purple markings, about 2½ in. long; galea slightly lanuginose. W. China.—*S. Forskøhlei*, Linn. (Sec. 3). Hardy perennial, 1½ ft. high: st. herbaceous, somewhat viscid-villous: lvs. broad-ovate: corolla violet. Orient. B.M. 988.—*S. Gardneriana*, Hort., is offered in the trade.—*S. globosa*, Hort. Biennial: lvs. in a flattened rosette 16–18 in. long, 10–12 in. broad, deeply cut, clothed with a silvery white tomentum: fl.-st. 3 ft. or more high, much branched, the branches forming a sphere: fls. large, white. Asia Minor. R.B. 37:28.—*S. Greigii*, Hort., is offered in the trade as a wooded shrub 2½–3 ft. high: fls. a soft shade of cerise, produced all summer. G.M. 57:713.—*S. Heerii*, Regel (Sec. 7, probably). Subshrub, 2–5 ft. high, with cordate-ovate or lanceolate lvs.: corolla scarlet. Peru. Gt. 4:115.—*S. indica*, Linn. (Sec. 5). Perennial herb, about 3 ft. high, with broad or oblong-ovate lvs., the floral ones ovate-cordate, reflexed: corolla yellow spotted with purple. Syria. B.M. 395.—*S. interrupta*, Schousb. (Sec. 1). Hardy subshrub, 3–4 ft. high, with

irregularly pinnatisect lvs., the extreme segm. much larger than the others: corolla showy, dark violet-purple with a white throat. Morocco, B.M. 5860.—*S. lamiifolia*, Jacq. (*S. amœna*, Sims) (Sec. 7). Shrub, about 2 ft. high, with ovate, serrate-crenate lvs.: corolla blue, the upper lip covered with whitish blue wool. W. Indies. B.M. 1294. B.R. 446. L.B.C. 4:377.—*S. lavenduloides*, HBK. (*S. lavenduliformis*, Neum.) (Sec. 7). Perennial herb, with very short-petioled, oblong-lanceolate lvs.: spikes 2-3 ft. long; corolla pale blue, small. Mex. R.H. 1845:445.—*S. leonuroides*, Glox. (*S. formosa*, L'Her.) (Sec. 7). Shrub, about 3 ft. high, with ovate or rhomboid lvs.: the floral whorls in the axils of the cauline lvs. not racemose; corolla scarlet. Peru and Brazil. B.M. 376.—*S. macrostachya*, HBK. (Sec. 7). Shrub, about 6 ft. high, with subrotund-ovate lvs., their base deeply cordate, the auricles rounded; the floral lvs. large, green; corolla blue, the lower lip longer than the galea. Peru. B.M. 7372.—*S. oazacana*, Fern. (Sec. 7). Shrub, much branched: lvs. ovate, pale green and strongly rugose above, white-tomentose beneath: floral whorls mostly 2-fld.; corolla cardinal-red, nearly 1½ in. long. Mex.—*S. oppositiflora*, Ruiz & Pav. (Sec. 7). Half-hardy subshrub, about 2 ft. high, with ovate, pubescent lvs.: floral whorls 2-fld., secund, calyx striate; corolla scarlet. F.S. 4:345. P.M. 15:53. Gt. 4:212.—*S. princeps*, Hort. (Sec. 7). Subshrub, 3-6 ft. high: lvs. large, ovate-serrate, with the principal veins prominent; spikes large, terminating the branches; calyx colored; corolla brilliant carmine-rose, slightly ventricose, lfts. small. Mex. R.B. 33:257. Resembles *S. splendens*.—*S. prunelloides*, HBK. (*S. brunellodes*, Voss) (Sec. 7). Several herbaceous sts. from a perennial base: lvs. ovate-oblong, both surfaces green; corolla blue. Mex. P.M. 11:175. Var. *purpurea*, Hort., has the fls. purplish red.—*S. rutilans*, Carr. (Sec. 7). A plant with a small green calyx and usually 2-fld. floral whorls. Probably a horticultural form of *S. splendens*. R.H. 1873:250. G.C. II. 15:117(?).—*S. scabiosifolia*, Lam. (*S. Hablitziana*, Willd.) (Sec. 1). Perennial herb, 1-1½ ft. high, with pinnatisect lvs.: segms. 3-5-jugate, frequently in pairs or 3's; corolla white. Tauria. B.M. 1429 and 5209.—*S. scapiformis*, Hance (Sec. 11). Perennial herb: lvs. radical, broadly ovate or oblong-ovate; scapes 6-10 in. high; the floral whorls numerous; corolla amethystine. Formosa. B.M. 6980.—*S. Sieheana*, Hort., is described as perennial, and having large light lilac fls.—*S. Solletii*, Duthie. Perennial, about 2 ft. high; sts. herbaceous: lvs. dark green, triangular, rugose; fls. numerous, tubular-lipped, delicate shade of blue. China.—*S. strictiflora*, Hook. (Sec. 7). Shrub, about 2 ft. high, with ovate, pale green, slightly fleshy lvs.: fls. stiffly erect, tubular and golden red. Peru. B.M. 3135. P.M. 11:247.—*S. taraxacifolia*, Coss. & Bal. (Sec. 1). Subshrub, 6-13 in. high, with lvs. 2-4 in. long, pinnatisect, terminal lobe 1-1½ in. long, ovate and irregularly sinuate-toothed, all white-tomentose beneath: corolla pale pink with a yellowish disk to the lower lip and a purple-speckled palate. Morocco. B.M. 5991.—*S. tricolor*, Lem. (Sec. 7). Half-hardy shrub, about 2 ft. high, with small ovate lvs. rounded-obtuse at the apex, with a terminal tooth: corolla white, the lower part of the larger lower lip reddish. Mex. I.H. 4:120. F.S. 12:1237.

F. TRACY HUBBARD.

SALVINIA (Antonio Maria Salvini, 1633-1729, Italian scientist). *Marsiliaceæ*. An interesting plant for the small home aquarium. *Salvinia* is a genus of fern-allies found mostly in the tropics and comprising about a dozen species, only one of which, *S. natans*, Linn. (Fig. 3540), is cultivated.

Plants floating, with slender sts. bearing apparently 2-ranked, oblong lvs. 4-6 lines or even 1 in. long: upper surface of lvs. covered with papillæ or minute warts; lower densely matted with brown pellucid hairs. The plant is supposed to have no true roots. What look like roots are believed to be finely dissected lvs.; one of these occurs with each pair of the foliage-lvs. Many aquatic plants have these 2 types of foliage, e. g., the water buttercup, *Ranunculus aquatilis*. *Salvinia* looks much like a flowering plant but it is a spore plant and has

3540. *Salvinia natans*. (Xabout 1)

2 kinds of spores, large ones and minute ones. These spores are produced in small oval bodies known as sporocarps, i. e. "spore-fruits." Of each cluster of sporocarps, 1 or 2 contain 10 or more sessile macrosporangia, each of which contains a solitary macrospore. The other sporocarps in the cluster contain numerous microsporangia, each of which contains numerous microspores.

The plant is of easy culture in summer, but many persons have lost it over winter by not understanding its habits. It is an annual and often dies in the winter after ripening a crop of spores. Secure a broad pan, fill it half full of loam and then fill the pan with water. After the water has cleared place the salvinias on the sur-

face. In the winter watch for the formation of the spore-capsules. These grow in masses near the top of the clusters of root-like leaves. After the plants die the spore-capsules will remain in the soil. The plant often passes the winter in greenhouses in a growing condition, producing no spores. R. C. BENEDICT.†

SAMANEA (a corruption of its native Spanish name of *zaman*). *Leguminosæ*. Spineless or rarely spiny trees or shrubs of the American tropics, where one or two of them are much planted for shade.

3541. *Samanea saman*.

Leaves several- or rarely many-pinnate; lfts. 1- to many-pinnate: fls. in globose heads: pods straight or somewhat curved, rigid, more or less constricted, flat, thickened or subterete, leathery or fleshy, indehiscent or rarely but slightly so; septate between the seeds. Distinguished from *Enterolobium* by the nearly straight pods and from *Pithecolobium* by its indehiscent septate pods.—About 30 species.

A. Lvs. 2-4-pinnate; lfts. 2-8-pinnate.

Samán, Merrill (*Mimosa Samán*, Jacq. *Pithecolobium Samán*, Benth. *Enterolobium Samán*, Prain). RAIN TREE. ZAMAN. SAMAN. Figs. 3541, 3542. A large tree, reaching a height of 60-80 ft., with wide-spreading branches; branchlets velvety pubescent: lvs. 2-4-pinnate; lfts. 2-8-pinnate, oblique, ovate-oblong or suborbicular, up to 1½ in. long, shining above, pubescent beneath: peduncle 4-5 in. long: fls. in heads, in short pedicels; calyx ¼ in. long, pubescent; corolla about ½ in. long, yellowish; silky, villous; stamens 20, light crimson, shortly connected: pod sessile, straight, thick-margined, leathery-fleshy, glabrous, indehiscent, 6-8 in. long, ½-1 in. broad, flattened or subterete. A native of Cent. Amer. and the W. Indies, but now widely distributed in the tropics as an ornamental shade tree. Blanco, Fl. Filip. 309. Jacq. Fragm. 9. G.C. III. 11:557.—The lfts. fold together on the approach of rain. A rapid grower. The pods contain a rich sugar-pulp and are eagerly eaten by cattle and horses. The seeds are of little food value as they are not digested and often cause slight digestive troubles. The pods when eaten by cows are said to increase the quality of their milk.

AA. Lvs. 5-12-pinnate; lfts. 20-30-pinnate.

arboreum, Ricker (*Mimosa arborea*, Linn. *Mimosa filicifolia*, Lam. *Pithecolobium filicifolium*, Benth. *Pithecolobium arboreum*, Urban). A magnificent tree, 50-75 ft. tall, ferruginous-tomentose: lvs. 8-12-pinnate; lfts. 20-30-pinnate, oblique, falcate-oblong, obtuse, ¼-½ in. long, glabrescent: peduncles axillary or above the axils, 2-3 in. long: fls. white, sessile in globose heads, often pubescent; calyx 1 line long, corolla ¼ in. long: pod red, tomentose when young, becoming glabrous, terete, fleshy, constricted between the seed, slightly curved or twisted, 2-3 in. long, ⅓-½ in. broad, finally somewhat dehiscent; seeds black. Trop. Amer.

P. L. RICKER.

SAMBUCUS (old Latin name for the elder, also spelled *Sabucus*). *Caprifoliaceae*. ELDER. Ornamental mostly woody plants grown for their handsome foliage, showy clusters of white flowers, and the attractive red or black berries.

Deciduous shrubs or small trees, with stout very pithy branches, rarely perennial herbs: lvs. opposite, odd-pinnate, with serrate lfts., with or without stipules and stipels: fls. small, usually perfect, white, in terminal compound cymes or panicles, usually 5-merous, rarely 3- or 4-merous; calyx-lobes minute; corolla rotate with short tube and oval to oblong-lanceolate lobes; stamens with short filaments; ovary inferior, 3-5-celled; style short, 3-5-lobed: fr. a drupe with 3-5 1-seeded nutlets.—About 20 species in the temperate and subtropical regions of both hemispheres. Some species, particularly *S. nigra* and *S. canadensis*, possess medicinal properties; the fr. of these species and also that of *S. cærulea* is used in cookery, also elderberry wine is made from it. The hard wood, the large pithy shoots which are easily hollowed and the pith are put to various uses. Monograph of the genus by Count Schwerin in M.D. 1909, pp. 1-56.

The elders are large and rather coarse shrubs, rarely tree-like, or perennials spreading by suckers, with pinnate foliage and large flat or paniced clusters of white or creamy white small flowers followed by red or black, rarely glaucous or in some varieties green or yellow fruits. They are well adapted for mass planting and are very effective as well in bloom as in fruit in their proper places. They prefer rich and humid soil and most species are hardy North; *S. cærulea* and its var. *neo-mexicana* are hardy at least as far north as Massachusetts. Propagation is by seeds which germinate readily and by hardwood and greenwood cuttings, also by root-cuttings; the perennial species and also *S. canadensis* by suckers.

3542. *Samanea Saman*. (×¼)A. *St. woody*.

B. Berries black or dark purple, rarely green or white: pith white: cymes flat.

C. Fr. not glaucous.

1. *nigra*, Linn. EUROPEAN ELDER. Large shrub or tree, to 30 ft., with deeply furrowed bark: all parts when bruised exhaling a disagreeable odor: branches gray, strongly lenticellate: lvs. dark green, usually pubescent beneath while young; lfts. 3-7, usually 5, short-stalked, elliptic, acute, serrate, 2-6 in. long: cymes 5-rayed, to 5 in. across: fr. black, lustrous, 3-celled, ¼-½ in. across. May, June: fr. Aug., Sept. Eu., W. Afr., W. Asia. S.E.B. 4:637. R.F.G. 12:780. H.W. 3, p. 132. G.C. III. 10:405. Many varieties: Var. *pyramidata*, Lav. (var. *pyramidalis*, Dipp.). Habit columnar. Var. *pendula*, Dipp. Pendulous or prostrate. Var. *nana*, Schwerin. Forming a globose bush about 3 ft. high; weak-growing. Var. *rotundifolia*, Endl. Lfts. 3, rarely 5, broadly ovate to suborbicular. Var. *laciniata*, Willd. (*S. laciniata*, Mill.). Lfts. regularly and finely dissected. R.F.G. 12:780. A handsome and distinct form. Var. *heterophylla*, Endl. (var. *linearis*, Kirchn.). Lfts. irregularly cut and erose and partly reduced to the midrib; slow-growing form. Var. *latisecta*, Hesse. Lvs. broadly lobed. Var. *albo-variegata*, Endl. Lvs. variegated with white. J.H.S. 33, p. 360, fig. 47. G.W. 11, p. 474. Var. *pulverulenta*, Sweet. Lvs. finely dotted and sprinkled with white. Var. *aurea*, Sweet. Lvs. golden yellow. G.W. 2, p. 565. Var. *viridis*, Ait. (var. *chlorocarpa*, Hayne. Var. *viridescens*, Sweet). Fr. pale green, striped whitish. M.D. 1908:8, fig. 2.

2. *canadensis*, Linn. AMERICAN OR SWEET ELDER. Fig. 3543. Shrub, to 12 ft., stoloniferous: branches pale yellowish gray, slightly lenticellate: lvs. bright green; lfts. usually 7, short-stalked, elliptic to lanceolate, acute or acuminate, sharply serrate, sometimes pubescent on the veins beneath, 2-5 in. long: cymes 5-rayed, to 10 in. across: fr. purplish black, usually 4-celled. June, July; fr. in Sept. Nova Scotia and Man. to Fla. and Texas. B.B. (ed. 2) 3:268. G. 27:541. M.D.G. 1899:169. Var. *submollis*, Rehd. Lvs. grayish green and soft-pubescent beneath. Ill. to Ark. and Texas. Var. *maxima*, Hesse. Lvs. larger: cymes to 18 in. across. Very vigorous grower. G.W. 11, p. 397. G.M. 51:451. Var. *acutifolia*, Ellwanger & Barry (var. *laciniata*, Cowell). Lvs. much dissected, the lower lfts. pinnatifid, the upper ones incisely serrate and narrowly lanceolate. A very handsome and distinct form. F.S.R. 1, p. 151. Var. *aurea*, Cowell (var. *delicatissima*, Schwerin). Lvs. golden yellow: berries cherry-red. F.E. 22:433. Var. *chlorocarpa*, Rehd. Fr. greenish: lvs. pale yellowish green.—The handsomest and most effective of the elders in bloom, also attractive when weighed down with its large clusters of purplish black berries.

CC. Fr. glaucous.

3. *cærulea*, Raf. (*S. glauca*, Nutt.). Large shrub or small tree, occasionally to 50 ft.: branchlets rather slender, bloomy when young: lfts. 5-7, oblong, long-acuminate, coarsely serrate, the lower lfts. often 3-parted or pinnate, bright green, glabrous, 2-6 in. long: fls. yellowish white, in flat cymes 4-6 in. wide: fr. subglobose, ¼ in. thick, blue-black, whitened by a thick bloom. June, July; fr. in Aug. and Sept. Brit. Col. to Calif., east to Mont. and Utah. S.S. 5:222. G.W. 8:116. Var. *velutina*, Schwerin (*S. velutina*, Durand). Young branchlets and lvs. covered with a dense and short whitish pubescence. Calif. Var. *neo-mexicana*, Rehd. (*S. glauca* var. *neo-mexicana*, A. Nels. *S. intermedia*, Carr.). Lfts. 3-5, narrow-lanceolate, grayish green, slightly pubescent beneath. New Mex., Ariz. M.D. 1909:8, fig. 1.—This species is similar to *S. canadensis*, but habit looser and taller, very striking with its large clusters of bluish white frs.; the typical

form and var. *neo-mexicana* have proved hardy as far north as Mass.

BB. Berries red, rarely yellow: pith light brown: cymes convex or paniculate.

4. *racemosa*, Linn. RED-BERRIED ELDER. Shrub, to 12 ft.: branches light brown; young branchlets glabrous or nearly so, 2-3½ in. long: infl. ovate or oblong, dense: lfts. 5-7, ovate or elliptic to ovate-lanceolate, glabrous, 2-3 in. long: fls. yellowish white: fr. scarlet, ¼ in. across, 3-seeded; nutlets yellowish white, minutely rugose. April, May; fr. in June, July. Eu. to E. Asia. H.W. 3, p. 133. R.F.G. 12:781. Var. *nana*, Carr. Dwarf compact form. Var. *plumosa*, Carr. Lfts. incisedly serrate to about the middle, teeth long and

3543. *Sambucus canadensis*. (×¼)

narrow, purplish when unfolding. Var. *plumoso-aurea* Weezelenburg (var. *serratifolia aurea*, Barbier). Foliage like that of the preceding form, but golden yellow. Var. *ornata*, Carr. (var. *pteridifolia*, Carr.). The first lvs. of the shoot are like those of var. *plumosa*, the later ones more finely dissected like var. *laciniata*. Var. *laciniata*, W. Koch (var. *serratifolia*, Hort.). Lfts. regularly and deeply dissected, green when unfolding. R.F.G. 12:781. Var. *tenuifolia*, Carr. Lvs. finely and deeply dissected with very narrow segms., purplish when unfolding. Var. *purpurea*, Sweet (S. *rosiflora*, Carr.). Fls. purplish or pink outside, purple in bud. G. 3:175. Var. *flavescens*, Sweet (var. *xanthocarpa*, Zabel). Fr. yellow with orange cheek. M.D. 1909:8, fig. 6.—This species, like the following, is not conspicuous in bloom, but the clusters of scarlet fr. are very attractive in June and July. The cut-leaved forms are very graceful.

5. *pubens*, Michx. (S. *pubescens*, Pers. S. *racemosa* var. *pubens*, Koehne. S. *racemosa* var. *pubescens*, Dipp., not Miq.). Shrub, to 12 or sometimes to 25 ft.: branch-

lets and lvs. on both sides finely pubescent while young, sometimes nearly glabrous at maturity; lfts. 5-7, ovate-oblong to oblong-lanceolate, acute, serrate, pubescent beneath, rarely nearly glabrous: infl. ovate or pyramidal, looser and broader at the base than that of the preceding species, to 4 in. long; berries scarlet; nutlets minutely rugose. May: fr. in June, July. New Bruns. to Alaska, south to Ga., Colo. and Brit. Col. B.B. (ed. 2) 3:268. Var. *dissecta*, Brit. (S. *racemosa* var. *laciniata*, Rob. & Fern., not W. Koch). Lfts. deeply and regularly dissected. Var. *leucocarpa*, Bernh. (var. *albicocca*, Brit. Var. *xanthocarpa*, Cock.). Fr. whitish or amber-yellow. Var. *arborescens*, Dipp. Tree-like; less pubescent.

AA. St. herbaceous: plant stoloniferous: cymes flat: fr. red.

6. *Schweriniäna*, Rehd. Herbaceous or suffruticose, stoloniferous, glabrous, 3-5 ft.: lfts. 5-7, oblong-lanceolate, the lower ones short-stalked, the upper ones adnate and decurrent, acuminate, very unequal at the base, serrate, 3-5 in. long: cymes flat, long-stalked, 5-rayed, puberulous: fr. salmon-red, 3-seeded, ¼ in. thick; nutlets broadly ovoid, smooth. W. China.—Handsome with its clusters of bright red fruit; it spreads rapidly by suckers and may become a weed difficult to eradicate, therefore it should not be planted where it is likely to become troublesome.

S. *callicarpa*, Greene (S. *leiosperma*, Leiberg. S. *racemosa* var. *callicarpa*, Jepson). Allied to S. *pubens*: shrub to 10 ft.: lfts. oblong to lanceolate, pubescent on the veins beneath while young; infl. broadly pyramidal or hemispherical: nutlets smooth. Alaska to Calif., Japan. M.D. 1909:8, fig. 5. G.F. 10:175. Mn. 2:21 (as S. *pubens*). —S. *chinensis*, Lindl. = S. *javanica*. —S. *Eubulus*, Linn. Herbaceous, stoloniferous, to 5 ft.: lfts. 5-9, elliptic-lanceolate, serrate, pubescent; stipules large: cymes flat, 3-rayed; fls. white or pinkish, anthers purple, fragrant: fr. black, ¼ in. across. Eu., Afr., W. Asia. R.F.G. 12:779. S.E.B. 4:638. —S. *Fontenayensis*, Carr. (S. *cærulea* × S. *nigra*). Intermediate between the parents: lvs. bluish green: cymes large: fr. black, bloomy. Garden origin. —S. *javanica*, Reinw. (S. *chinensis*, Lindl. S. *Thunbergiana*, Blume). Suffruticose, to 6 ft.: lfts. 5-7, elliptic-lanceolate, the upper ones sometimes decurrent, long-acuminate, sparingly pubescent while young, to 8 in. long: cymes flat, 5-6 in. across, with scattered large aborted fleshy fls.: fr. ovoid, red. Japan, China to Malay Archipelago. —S. *leiosperma*, Leiberg = S. *callicarpa*. —S. *melanocarpa*, Gray. Allied to S. *pubens*. Shrub, to 12 ft.: lfts. oblong-lanceolate, pubescent beneath while young, 4-5 in. long: infl. ovate: fr. ¼ in. thick, black, rarely reddish brown. Brit. Col. to Calif. G.F. 10:135. M.D. 1909:8, fig. 4. I.T. 5:173. —S. *mexicana*, D.C. (S. *canadensis* var. *mexicana*, Sarg.). Tree, to 30 ft.: lvs. 5-9-foliolate, sometimes bipinnate; lfts. ovate-lanceolate, long-acuminate, pubescent on both sides while young, later only below, 2-6 in. long: cymes flat, 6-8 in. across: fr. nearly black, ribbed, ¼ in. across. W. Texas to S. Calif., Mex. S.S. 5:221. In Mex. planted sometimes near houses as a shade-tree and for its fr. —S. *microbotrys*, Rydb. Allied to S. *pubens*. Shrub, to 6 ft., glabrous lfts. ovate-lanceolate, long-acuminate, to 5 in. long: infl. small, nearly hemispherical, about 2 in. long: fr. scarlet. Calif. to Colo. and Nev. —S. *Sieboldiana*, Graebn. (S. *racemosa* var. *Sieboldiana*, Miq.). Closely related to S. *racemosa*: lfts. oblong-ovate to lanceolate, smooth, not rugulose above, more finely serrate, to 4 or occasionally to 8 in. long: fls. and frs. smaller. Japan, China. S.I.F. 2:74 (as S. *racemosa*). —S. *Simpsonii*, Rehd. Allied to S. *canadensis*. Small tree, to 15 ft., with deeply furrowed bark: lfts. usually 5, elliptic to elliptic-oblong, lustrous above, glabrous, 1½-3 in. long: cymes with 4 or 5 rays, the central ray as long or longer than the lateral rays; ovary 5-celled. Fla. S.T.S. 2:175. —S. *Thunbergiana*, Blume = S. *javanica*. The plant cult. under this name is S. *racemosa* or possibly sometimes S. *Sieboldiana*.

ALFRED REHDER.

SAMPHIRE (*Crithmum maritimum*, which see) is the name corrupted from *sampier*, itself a corruption of the French *Saint Pierre* (St. Peter), given to a succulent-stemmed half-hardy perennial, well known as sea-fennel, parsley-pert, and St. Peter's herb upon rocky coasts above high tide in Great Britain. It belongs to the family *Umbelliferae*. The plants, which attain a height of 1 to 2 feet, have somewhat linear glaucous-green fleshy leaves, ½ inch long, small white or yellowish flowers, which appear in umbels during July, and oblong yellowish fennel-like smallish seeds of light weight, which ripen in early autumn and lose their germinating power within a year. For more than three centuries the crisp and aromatic leaves and young stems gathered in August or September have been used in salads and vinegar pickles. Samphire rarely reaches perfection in gardens far from the seacoast, unless

CII. *Sambucus canadensis*, the American sweet or summer-flowering elder.

grown upon sandy or gravelly soil, and watered frequently and plentifully with weak salt- and soda-solutions. It may be propagated by root-division, but better by sowing the seed as soon as ripe, the plants being thinned to stand from 1 to 1½ feet asunder in rows 2 to 2½ feet apart.

Golden samphire (*Inula crithmifolia*), a native of the marshes and seacoast of Great Britain, is an erect hardy perennial, 1 to 1½ feet tall, with small, fleshy leaves and yellow flowers in small, umbel-like clusters. Though grown and used like true samphire, for which it is often sold, it lacks the pleasing, aromatic taste of the genuine. It belongs to the family *Compositæ*.

For marsh samphire, see *Salicornia*. M. G. KAINS.

SAMUËLA (Sam Farlow Trelease, who participated in field-studies of the species). *Liliaceæ*, tribe *Yuccææ*. Yucca-like large plants.

Short-trunked mostly unbranched soft-pulped trees, resembling the baccate yuccas except in their gamophyllous perianth which in one species has a long slender tube resembling a tuberos. As in *Yucca Treculeana*, but to a greater extent, the bracts of the ample panicle are long and add much to its attractiveness.—Two species, one Texan and the other of the Mexican tableland. Hardy only in the S. where, as in Calif. and along the Riviera, they are said to be beginning to be cult. Monograph by Wm. Trelease in Rept. Mo. Bot. Gard., vol. 13, pp. 116-19.

Faxoniana, Trel. Lvs. in a dense round head, 2-3 in. wide and 3 ft. long, nearly smooth, deeply concave, pungent, with long coarse curving white marginal fibers: infl. loosely branched, 3 ft. or more long; fls. white, 2-4 in. across, with conical tube about ¾ in. long; fr. 1 by mostly 2-3 in. S. W. Texas. Rep. Mo. Bot. Gard. 4:4, 5; 13:73-5, 82, 85. S.S. 10:499.

carnerosana, Trel. Infl. 5-6 ft. high, compactly branched, with very large white bracts; fls. white, 3-4 in. across, with cylindrical tube ½-1 in. long; fr. 1½ x 2-3 in. E. Mex. Rep. Mo. Bot. Gard. 13:76-9, 80, 85, 87, and frontispiece to p. 27. WILLIAM TRELEASE.

SANCHÈZIA (after Jos. Sanchez, professor of botany at Cadiz). *Acanthaceæ*. Showy warmhouse plants, grown for flowers and foliage.

Strong erect herbs or half-shrubby plants: lvs. large, opposite, entire or slightly toothed: fls. orange, red, or purple, united into heads or spikes at the ends of the branches, or rarely paniculate; calyx deeply 5-parted, segms. oblong; tube of the corolla long, cylindrical, somewhat ventricose above the middle, limb of 5 equal, short, rotund lobes; perfect stamens 2, inserted below the middle of the tube, with 2 aborted stamens between them; anther 2-celled, the cells mucronate in front; style long, with one division small, spurlike; ovary on a thick disk, 2-loculed, with 4 ovules in each cell.—About 11 species in Peru, Colombia, and Brazil.

nobilis, Hook. Plants stout, erect, smooth, except the infl.: st. 4-angled: lvs. 3-9 in. long, oblong-ovate to oblong-lanceolate, obtusely toothed, narrowed into winged petioles, connate: fls. 2 in. long, yellow, in heads subtended by bright red bracts, the heads forming a panicle. Ecuador. B.M. 5594. F.S. 23:2437. G.W. 10, p. 610. G.Z. 11:16. H.F. II. 9:346. Var. *glaucochylla*, Lem. (var. *variegata*, Hort.). Lvs. variegated with pale yellow or white along the veins. F. 1867, p. 154. I.H. 14:528 (as *S. nobilis*); 16:580.—A hothouse plant which is very attractive when well grown, but which becomes straggling and weedy if neglected. Grown mostly for its foliage. *S. parvibracteata*, Sprague & Hutch. Allied to *S. nobilis*, from which it differs in having wingless petioles, smaller bracts with fewer (3-5) fls. and longer staminodes. Corolla yellow. Trop. Amer.

HEINRICH HASSELBRING.

SANDERSÒNIA (named after John Sanderson). *Liliaceæ*. Herb, suitable for the greenhouse: sts. suberect, simple, leafy: lvs. linear-lanceolate: fls. showy, orange, solitary in the axils, without bracts; perianth persistent, urn-shaped to globose, somewhat inflated; stamens 6; ovary sessile: fr. unknown.—One species, S. Afr. Treatment the same as for gloriosas.

aurantiaca, Hook. Rootstock tuberous: st. simple, 1-2 ft. high, leafy to the apex: lvs. sessile, alternate, linear or lanceolate, 2-4 in. long: perianth bright yellow, ¾-1 in. long. Nov. Natal. B.M. 4716. R.H. 1868, p. 311. J.F. 4:408.

SANGUINÀRIA (Latin, *blood*; referring to the yellowish red juice of the plant). *Papaveraceæ*. BLOODROOT. Low spring-blooming perennial used for borders and for rock-gardens.

3544. Bloodroot.—*Sanguinaria canadensis*. (× ½)

Rootstock several inches long, about ½ in. thick, horizontal: lvs. radical, cordate or reniform, usually only 1 from each root-bud, on petioles about 8 in. long: fls. white, often tinged with pink, 1-3 in. across, mostly solitary, on scapes about 8 in. long, appearing just preceding the full-grown lvs.; sepals 2, fugacious; petals 8-12, in 2 or 3 rows, oblong or obovate, early deciduous: caps. 1 in. long, oblong, 2-valved.—A single species common in woods of E. N. Amer., running into several forms (see Fedde in Engler's *Pflanzenreich*, iv, 104).

The bloodroot is a showy spring flower usually found in woodland, but not a true shade-loving plant, since its growth is made, to a great extent, before the foliage of the trees expands. In cultivation it prefers a rather light soil, but will grow anywhere. It will do as well in sunlight as in shade and will even grow amongst grass, if care be taken not to mow down the leaves until it has perfected the root growth and buds for the following season. The roots are best transplanted after the leaves have ripened, August-dug and -planted roots being best, but they may be moved when the plants are in flower. The roots are offered at such low prices by collectors that the plant should be used to a much greater extent for spring gardening.

canadensis, Linn. BLOODROOT. RED PUCCOON. Fig. 3544. Described above. April, May. B.M. 162. G.F. 8:215. G.C. III. 51:284. G. 31:447; 34:329. Gn.M. 3:134. Var. *majior*, Hort., is merely a form with large fls. J.H. III. 52:457. Var. *plena*, Hort., has more numerous narrower petals. F. W. BARCLAY.

SANGUISORBA (Latin, *blood and drink up*, from reputed styptic properties in folk-medicine). *Rosaceae*. Chiefly perennial herbs, grown as salad plants and also sometimes used in the hardy border.

Leaves unequally pinnate; stipules adherent to the petiole; fls. small, often polygamous or dioecious, crowded in a dense head or spike at the summit of a long, naked peduncle; calyx-tube persistent, with 4 broad petal-like spreading deciduous lobes; petals none; stamens 4-12: achene (commonly solitary) inclosed in the 4-angled dry and thickish calyx-tube.—About 35 species, natives of the North Temperate Zone. See *Poterium*.

minor, Scop. (*Poterium Sanguisorba*, Linn.). BURNET. Perennial, growing in clumps, glabrous or sparsely hairy: lvs. long, odd-pinnate, narrow, the small lfts. 6-10 pairs and orbicular to oblong and deep-toothed: sts. 1-2½ ft. tall, terminating in small globular or oblong heads: lower fls. in the head staminate, the others perfect, the stigmas purple, tufted and exserted. Eu., Asia, and naturalized in this country.—Sometimes grown in the herb-garden for the fresh young lvs., which are used in salads. It is also an interesting plant for the hardy border. Also recommended as a pasture plant, particularly for sheep. It thrives in dry soils.

canadensis, Linn. Taller, larger in every way than the above: lfts. oblong to almost triangular-oblong, truncate or cordate at the base, long-stalked, obtuse, sharp-toothed: fl.-heads cylindrical, 2-6 in. long, the fls. all perfect, whitish. Low grounds, Mich., east and south.—An interesting plant, worthy a place in the hardy border, and sometimes sold for that purpose. It produces much foliage. Grows 5-6 ft. tall.

S. atrosanguinea, Hort., is a form listed in the trade as having wiry sts. 3 ft. high bearing heads of rich crimson fls. Possibly the European *S. officinalis*, Linn.

F. TRACY HUBBARD.†

SANÍCULA (name said to be from *sanare*, to heal; or perhaps from *San Nicolas*). *Umbelliferae*. SANICLE. BLACK SNAKEROOT. Perennial rather tall glabrous herbs, useful sometimes as a ground-cover.

Leaves few, palmately lobed or parted, those from the base long-petioled: umbels irregular or compound; fls. greenish or yellowish, capitate in the umbels, perfect and with staminate ones intermixed; involucre and involucels few-lvd.: fr. globular, carpels not separating spontaneously, ribless, thickly clothed with hooked prickles.—About 39 species (Wolff, *Das Pflanzenreich*, hft. 61), temperate regions of the world. The sanicles have no particular horticultural merit, being rather weedy in habit; but they are useful in wild-gardens and for colonizing in woods.

A. Fls. yellow.

Ménziesii, Hook. & Arn. St. solitary, 1-2½ ft. high, branching: lvs. round-cordate, 2-3 in. across, very deeply 3-5-lobed: fr. about 1 line long, becoming distinctly pedicellate. Calif. and northward.

AA. Fls. purple (rarely yellowish).

bipinnatifida, Douglas. About 1 ft. high, with a pair of opposite lvs. at the base and 1-3 above, long-petioled, triangular to oblong in outline, 2-3 in. long, pinnately 3-5-lobed: fr. sessile. Calif. to Brit. Col.

AAA. Fls. greenish white.

marilandica, Linn. St. stout, 1½-4 ft. high: lvs. bluish green, the basal long-petioled, the upper sessile, 5-7-parted: fr. sessile. Atlantic to Brit. Col. Common in woods.

F. TRACY HUBBARD.†

SANSEVIERIA (after Raimondo de Sangro, Prince of Sansevero, born at Naples 1710. The spelling *Sansevera* is not the earliest). *Liliaceae*. BOWSTRING HEMP. Herbaceous perennials, essentially tender foliage plants, although beautiful in flower, adapted to the

coolhouse. They are grown for the stiff erect lvs., which are usually variegated.

Rhizome short, thick, sometimes stoloniferous: lvs. in a basal rosette, thick cartilaginous, frequently elongated, rather flat or terete: scape simple, tall, stout: fls. greenish white, medium-sized or long, clustered in an often dense raceme; perianth-tube slender, sometimes very long; stamens 6; ovary free, 3-celled.—Trop. and S. Afr. and India; the most recent treatment is by N. E. Brown in *Kew Bulletin*, 1915, where 54 species are described. The genus is important in yielding fiber.

Sansevierias are easily propagated by division or they may be raised from leaf-cuttings about 3 inches long. These cuttings form roots in sandy soil after about one month, after which a long stolon-like bud is formed, which produces the new plant at some distance from the cutting. Sansevierias are well adapted to house decoration, since they do not require much sunlight. A rather heavy soil suits them best.

A. Lvs. flat or nearly so.

thyrsiflora, Thunb. (*S. guineensis*, Willd.). Lvs. 2-4 to a growth, from a stout creeping rootstock, erect and smooth, to 1½ ft. long and 3½ in. broad, lanceolate, acute or obtuse, on both sides marked with pale green transverse bands which become obscure with age, tapering into a channelled petiole: fls. greenish white, fragrant. Trop. Afr. B.M. 1179 (properly 1180).

AA. Lvs. concave.

zeylanica, Willd. Lvs. 1-3 ft. long, 8-15 in a cluster, sword-shaped, subterete, variegated with transverse markings of a grayish white: scape longer than the lvs.: bracts many: fls. whitish green, 1½ in. long. India. B.R. 160. Var. *Lauréntii*, Hort. (*S. Lauréntii*, Wildem.) has a band of creamy yellow ¼-½ in. or more wide along the lf.-margins in addition to the regular variegation. Trop. Afr. G.W. 13, p. 125. R.B. 30:169.

AAA. Lvs. cylindrical.

cylindrica, Bojer. Lvs. often 3-4 ft. long, 8-10 in a tuft, terete, solid within, dark green, often banded with paler lines, acuminate, occasionally furrowed: scape with infl. shorter than the lvs.: raceme about 1 ft. long; fls. creamy white, tinged with pink. Trop. Afr. B.M. 5093. G.C. III. 16:222. R.H. 1861, p. 448, 450.

The following species have been grown in various botanical gardens but are not known to be in general cult. unless otherwise specified. *S. ethiopica*, Thunb. Succulent, stemless subshrub: lvs. somewhat rosulate, suberect or erect-spreading, 5-16 in. long, thick, linear-lanceolate, acute, running out into white awl-like tips 2-3 in. long, concave-channelled, back strongly convex, sometimes transversely dark green-banded, margins red or white, somewhat glaucous: infl. 16-30 in. long; fls. white. S. Afr. B.M. 8487.—*S. arborescens*, Cornu, has sts. reaching a height of 4 ft., furnished entirely with short spreading lvs. E. Trop. Afr.—*S. conspicua*, N. E. Br., is a stemless herb: lvs. 3-5, lanceolate, 9-24 in. long, green on both surfaces, with dark lines above and rusty brown margins: fls. white. E. Trop. Afr.—*S. Cornui*, Gér. & Labr., is stemless, the lvs. not bordered and only a little striped at the base and on the outside. Senegambia; properly *S. senegambica*, Baker.—*S. Craspi*, Hort., is offered in the American trade as a form with variegated lvs.—*S. fasciata*, Cornu, is stemless: lvs. flat, leathery, 2½ ft. long, 5 in. broad in the middle, bright green, striped and bordered with brown. Congo.—*S. glauca*, Hort., not Haw., resembles *S. zeylanica*, but the lvs. are somewhat shorter and not striate. Cochinchina.—*S. grandis*, Hook. f. Stemless: lvs. few, rosulate, obovate-oblong, the largest 3-4 ft. long, 6 in. broad, dull green with broad bands of much darker green: scape 2 ft. high, bearing a densely fld. terminal spike-like panicle 2-3 ft. long; fls. pure white, about 2 in. across. Trop. Afr. B.M. 7877. It produces a very strong, silky fiber.—*S. intermedia*, N. E. Br., is very similar to *S. cylindrica*, but the lvs. are channelled, the edges of the channel being acute below and obtusely rounded above. E. Trop. Afr.—*S. libérica*, Gér. & Labr. Lvs. more than 3 ft. long, bordered with ivory-white, not striped. W. Trop. Afr.—*S. metallica*, Gér. & Labr., is closely allied to what is called *S. guineensis* having shorter and somewhat broader lvs., which have a metallic tint and fewer markings.—*S. rorida*, N. E. Br. (*Sanseverina rorida*, Lanza), is almost stemless: lvs. 2-ranked, erect-spreading, horn-shaped, terete beneath, deeply channelled above: scape flexuous, longer than the lvs.: panicle elongated with many short reflexed branches: fls. small. Italian Somaliland.—*S. Stuckyi*, Godefr., is stemless: lvs. quite cylindrical except a small furrow on the upper surface. E. Afr.—*S. zanzibárca*, Gér. & Labr., is short-stemmed: lvs. in a distichous rosette, subterete, without furrows, very rigid, up to 5-6 ft. long. Zanzibar.

F. TRACY HUBBARD.

SÁNTALUM (from the Persian *Chandal* which in turn is derived from the Sanscrit *Chandana*, the name of the tree). *Santalaceae*. Evergreen glabrous trees or shrubs, and one species, *S. album*, yields the sandalwood: lvs. opposite, rarely alternate, coriaceous: fls. axillary or in terminal trichotomous paniculate cymes, dioecious; perianth campanulate or ovoid, lobes 4, rarely 5, valvate with a tuft of hair on their face; stamens 5-4, short; disk of scales between the stamens; ovary at first free, finally half-inferior: drupe subglobose.—About 10 species, India, Malaya, Austral, and Pacific Islands. Plants more or less parasitic.

album, Linn. SANDALWOOD. A small evergreen glabrous tree: lvs. opposite, $1\frac{1}{2}$ -2 in. long, thin, elliptic-ovate or ovate-lanceolate, acute or subacute, narrowed into a slender petiole: panicles terminal and lateral; pedicels about equaling the perianth-tube: fls. at first straw-colored, then blood-red, inodorous even when bruised: drupe globose, size of a cherry, black when ripe. Deccan Penin. B.M. 3235. G.C. III. 49:20.—The wood is white or citron-colored, sweet-scented when dry, and is esteemed in India as a perfume.

SANTOLINA (derivation of name doubtful). Often, but incorrectly spelled *Sanctolina*. *Compositae*. Shrubs or rarely herbs, natives of Eu. and Asia, mostly in the Medit. region, sometimes grown in the open for ornament.

Leaves alternate, aromatic; margins tuberculously dentate or pinnately lobed, often finely divided: fl.-heads yellow or rarely white, of disk-fls. only, many-fld.; involucre mostly campanulate, squarrose, imbricated, appressed.—About 8 species.

Santolina is valuable for its distinct foliage and is used in the South for specimen planting and in the North for summer bedding and borders. Cuttings for the latter purpose are usually taken in the spring from plants wintered in a frame but may be taken before frost in the fall. They are easily rooted in sand.

Chamaecyparissus, Linn. (*S. incana*, Lam.). LAVENDER COTTON. A hardy half-shrubby, much-branched plant, $1\frac{1}{2}$ -2 ft. high, with evergreen, silvery gray lvs., having tiny ovate-oblong lfts. and small globular heads of yellow fls., borne in summer: heads solitary, terminal about $\frac{3}{4}$ in. diam.: branches and lvs. canescent. Medit. region. Gn. 78, p. 21. Var. *incana* differs but little from the type: involucre pubescent.

S. alpina, Linn., is *Anthemis montana*, Linn., which makes a pretty ground-cover and has yellow fls., but appears not to be in the trade. Gn. 75, p. 595.—*S. viridis*, Willd. An erect shrub: branches leafless: lvs. in 4 vertical ranks, toothed: involucral scales lanceolate. S. Eu. G. 36:25.

F. W. BARCLAY.

SANVITÁLIA (after a noble Italian family). *Compositae*. Usually low, much-branched herbs grown for their attractive yellow flowers.

Leaves opposite, petioled, mostly entire: heads of fls. small, solitary, with yellow or sometimes white rays; involucre short and broad, of dry or partly herbaceous bracts; receptacle from flat to subulate-conical, at least in fr.; its chaffy bracts concave or partly conduplicate: achenes all or only the outer ones thick-walled, those of the rays usually 3-angled, with the angles produced into rigid, spreading awns or horns, those of the disk often flat and winged.—About 4 species, natives of the S. W. U. S. and Mex. May be grown as an annual in the open, but if given protection it will sometimes flower the second year. Sanvitalias are of easy culture but prefer a light or sandy soil in full sunlight.

procumbens, Lam. A hardy floriferous annual, growing about 6 in. high, trailing in habit: lvs. ovate, about 1 in. long: fl.-heads with dark purple disk and yellow rays, resembling small rudbeckias, less than 1 in. across, numerous: achenes of the disk flattened and often winged and 1-2 aristellate. Summer to very late autumn. Mex. B.R. 707. R.H. 1860, p. 127. Var.

flôre-plêno, Hort. A double-fld. variety coming true from seed, and as vigorous as the type. R.H. 1866, p. 70.—Worthy of more extended use as a low border annual.

F. W. BARCLAY.

SAP, a term applied to the juices of living plants.

Sap is composed of water containing mineral salts absorbed from the soil, and organic substances chiefly constructed within living cells. The water taken from the soil by the roots or other absorbing organs may contain potassium, sodium, magnesium, calcium, iron, and nitrates, phosphates, sulfates, and chlorids. The different processes and the different reactions that take place in separate tracts of tissue are responsible for the fact that the sap is not alike in composition throughout the body of the plant.

The mineral elements and their salts may be found in nearly all saps. The limits of this note do not permit the enumeration of the large number of organic substances which may be found in the sap of various species. The more important of such compounds may be grouped under the acids, sugars, or carbohydrates and proteins. Many plants are of economic importance because of the materials dissolved in the sap. The sap of the sugar maple, for example, contains over $3\frac{1}{2}$ per cent of sugar, while the sugar-beet and sugar-cane have a sap in which the proportion is very much higher.

The popular expression of "ascent of sap" refers to the fact that water entering the living cells of the roots is forced into the woody tissues or non-living elements through which it passes upward to the leaves at a rate which may vary from a few inches to over a yard an hour. (See *Transpiration*.) The forces operative and the mechanism of the flow are not perfectly understood. Among other facts of interest it may be mentioned that the sap-current may pass through dead sections of stem, although it is equally certain that the activities of the living cells furnish at least a part of the motive power.

The flow of sap from the sugar maple and other trees in the early spring, before the soil has thawed and while it is yet too cold for the living matter of the plant to show any great activity, is not due to the bleeding pressure, but to the expansion of the gases and liquids in the trunk and branches of the tree due to the direct warming action of the sun's rays. During the daytime the bubbles of air in the wood-cells become heated and expand, driving the sap from the wood-cells into the auger-hole which has been bored into the tree. At night the trunk of the tree cools slowly and the flow ceases, to be begun again next day.

The exudation pressure by which water or sap is forced from the living cells is exhibited in the bleeding which ensues when stems and branches are cut away. The pressure which produces bleeding is often called root-pressure, although it is exerted by any part of the plant. Bleeding is exhibited by a large number of trees at the beginning of the growing season, and is also especially noticeable in the vine, dahlia, castor-oil plant, calla, nicotiana, and corn.

The amount of bleeding exhibited by any plant may be found if the stem is cut and bent over in such manner that the end is thrust into a tumbler or small vessel, which will serve to collect the escaping sap.

Interesting records of measurement of the amount of bleeding are available. A specimen of *Betula papyracea* gave off over sixty-three pounds of water in twenty-four hours; an *Agave americana* yielded twelve and one-half pounds in twenty-four hours. The pulque of Mexico is the preparation of sap which collects in the center of the mature rosette of agave when a cavity is cut into it.

The range of concentration of sap as denoted by its osmotic properties varies widely. Cacti and other succulents have a sap which would set up a pressure of only three to twelve atmospheres. Spinose desert shrubs may have a sap which would set up a pressure of over a

hundred atmospheres. The concentration is greatest in mature leaves, and in the lilac this may be from twelve to twenty-five atmospheres, while the roots of the same plant may not show more than four or six atmospheres.

D. T. MacDOUGAL.

SAPINDUS (Latin, *soap* and *Indian*, alluding to use of the fruit as soap in India). *Sapindaceæ*. SOAP-BERRY. Trees or shrubs, sometimes somewhat climbing, of economic use and sometimes used as ornamentals.

Leaves alternate, without stipules, abruptly pinnate or simple, 1-lvd. in one species; the lfts entire, rarely serrate: racemes or panicles terminal or axillary: fls. polygamous, regular; sepals 4-5, in 2 rows; petals 4-5, naked or bearing 1 or 2 glabrous or villous scales above the claw; disk annular; stamens 8-10: berry fleshy or leathery; seeds frequently globose, with a bony testa and no aril, black or nearly so.—About 15 species, tropical regions of the world.

The fruit has an alkaline principle known as saponin which makes it useful for cleansing purposes. The fruit was much used in eastern countries before the introduction of soap and is still preferred for washing the hair and cleansing delicate fabrics like silk. The seeds of some species are used for making rosaries, necklaces, and the like.

The soapberry trees in cultivation are evergreen or rarely deciduous trees with pinnate, rather large foliage and with terminal large panicles of small whitish flowers followed by berry-like globose orange-brown to black fruits. With the exception of *S. Drummondii*, which has proved fairly hardy in sheltered positions as far north as Massachusetts, they can be grown in subtropical regions only, but *S. Mukorossi* is apparently somewhat hardier than the rest. They are sometimes planted for ornament in the southern states and in southern California and some, particularly *S. Mukorossi* var. *carinatus*, may possibly be profitably planted for their fruits which are rich in saponin. They do well in rather dry and rocky or sandy soil. Propagation is by seeds which germinate readily and by hardwood cuttings in early spring.

A. Lfts. obtuse or acutish, 4-9; rachis usually broadly winged; petals without scales.

Saponaria, Linn. A small tree, to 30 ft., with rough grayish bark: lfts. oblong-lanceolate and acute to elliptic-ovate and somewhat obtuse, opposite or alternate, entire, glabrous, veiny and lucid above, tomentulose beneath, 3-4 in. long; rachis usually winged: panicle 7-10 in. long; sepals rounded, petals ovate, hairy: fr. $\frac{2}{3}$ - $\frac{3}{4}$ in. across, globose, keeled, orange-brown, translucent. Fls. in Nov.: fr. in spring. S. Fla., W. India, and S. Amer. Cult. in S. Fla. and S. Calif. S.S. 2:74, 75.

AA. Lfts. acuminate, 7-19; rachis with narrow margin or marginless: petals with 2 scales.

B. Trees evergreen.

marginatus, Willd. A tree reaching ultimately 60 ft. in height: lfts. very short-stalked or nearly sessile, 7-13, lance-oblong, acuminate, glabrous above, paler beneath and somewhat pubescent on the midnerve, 2-5 in. long; the upper nearly opposite, the lower alternate; rachis narrowly margined or marginless: fls. white, sometimes tinged with red, in pyramidal panicles; petals ciliate, ovate to ovate-lanceolate; filaments villous: fr. yellow, translucent, globose, keeled, $\frac{3}{4}$ in. across. May, June. S. C. to Fla. S.S. 13:623.—Cult. for ornament in S. Fla.

Mukorossi, Gaertn. Tree, to 60 ft.: lfts. 8-13, stalked, the stalk $\frac{1}{8}$ - $\frac{1}{2}$ in. long, oblong-ovate to oblong-lanceolate, oblique and cuneate at the base, glabrous, reticulate beneath, 3-6 in. long; rachis with narrow margin: panicles 5-8 in. long; sepals suborbicular to ovate, obtuse, petals ovate to ovate-lanceolate, acute,

ciliate; filaments villous: fr. globose, yellow or orange-brown, about $\frac{3}{4}$ in. across, slightly keeled. China, cult. in Japan. S.I.F. 1:71. Var. *carinatus*, Radlk. (*S. utilis*, Trabut). Fr. more fleshy, strongly keeled.—According to Trabut this variety is cult. in Algeria for its fr. which contains nearly 38 per cent of saponin; the trees come into bearing in 8-10 years and a tree may yield 60-120 pounds of berries every year.

BB. Trees deciduous.

Drummondii, Hook. & Arn. WILD CHINA TREE. SOAPBERRY. Tree, to 50 ft., with scaly red-brown bark: branchlets pubescent while young: lfts. 8-19, short-stalked, lanceolate, broadly cuneate and oblique at the base, glabrous above, pubescent beneath, 2-3 in. long; rachis marginless: panicles pubescent, 6-9 in. long; sepals acute, ciliate; petals much longer, ovate, pubescent inside; filaments villous: fr. subglobose, not keeled, $\frac{1}{2}$ in. across, yellow, finally black. May, June; fr. Sept., Oct. Ark., La. to Ariz. and N. Mex. S.S. 2:76, 77 (as *S. marginatus*). B.B.(ed. 2) 2:500.

ALFRED REHDER.

SAPIUM (the Latin name used by Pliny for a resiniferous pine). *Euphorbiaceæ*. Tropical trees and shrubs cultivated for their economic products and sometimes for ornament.

Glabrous: juice milky and poisonous: lvs. alternate or rarely opposite, simple, denticulate to entire; stipules small, 2 conspicuous glands at the apex of the petiole and on each of the scale-like bracts: fls. generally in terminal spikes, the pistillate singly below, the staminate in 3's above, all apetalous; calyx of staminate fls. 2-3-lobed, the lobes imbricate; stamens 2-3, filaments free; ovary 1-3-celled, 1 ovule in each cell; a 3-parted central column remaining after dehiscence of the caps.: seed without a caruncle.—Nearly 100 species, in the tropics of both hemispheres, but chiefly in Amer. Two intro. species are now found wild in S. Fla. Related to *Stillingia*, *Hura*, and *Homalanthus*.

In their native country a number of species of *Sapium* are utilized in many ways. They are chiefly important as a source of rubber. *S. Jenmanii* is the chief source of rubber in British Guiana, where it is found in the alluvial forests in humid situations. It does best in well-drained clayey peat. *S. verum*, once common in Colombia, has been cut for the rubber until it is now rare, but does well under cultivation in higher altitudes, yielding ten to eighteen pounds of raw rubber to each tree. A number of other species are used for rubber in South America. *S. Pavonianum* yields a medium grade. It is easily grown but is scarcely in cultivation. *S. sebiferum* is cultivated, especially in China, for the wax of the seed-covering which is used for candles, soap, and cloth-dressing. The wood of this and other species is utilized. Some of the "jumping beans" are seeds of *sapium* which contain insect larvæ. *Sapium* may be propagated by seeds or by cuttings. The best varieties are sometimes top-grafted on seedling stocks.

Pavonianum, Huber (*S. utile*, Preuss. *S. biglandulosum*, Muell. Arg. in part). PALO DE LECHE. Tree, 30-50 ft. high: lvs. oblong, lanceolate, or oblanceolate: spikes solitary, elongate: style cylindrical, not persistent on the caps.: the seeds with red, aril-like covering, soon separating from the central column. Colombia.

verum, Hemsl. VIRGIN RUBBER. CANCHO BLANCO. Tree, 60-75 ft. high: lvs. oblong-lanceolate to elliptical, acute at the base, apex rounded: style persistent on the caps.: otherwise similar to the foregoing species. Colombia and Ecuador.

Jenmanii, Hemsl. A large tree: lvs. oblong-lanceolate, abruptly and obtusely acuminate; glands of the petiole short, sessile; lateral lf.-veins more curved than in the preceding species and the ovary 1-celled: style not persistent. British Guiana.

sebiferum, Roxbg. (*Crôton sebiferus*, Linn. *Excoecaria sebifera*, Muell. Arg. *Stillingia sebifera*, Michx.). CHINESE TALLOW TREE. VEGETABLE TALLOW. Tree, 25-30 ft. high: lvs. broad rhombic-ovate, 1-3 in. broad, beautifully red-colored in age: racemes terminal: caps. $\frac{1}{2}$ in. thick; seeds long adhering to the central column, the aril-like coating white. China, and now cult. and naturalized in many tropical lands.

Among the species noted for their very poisonous juice are: *S. indicum*, Wild., with white bark and oblong willow-like lvs., in India, and *S. Hippomane*, Mey., MILK TREE, POISON TREE, with thick elliptical lvs. with the apex cucullate inflexed. W. Indies to Brazil.

J. B. S. NORTON.

SAPODILLA is the name applied in the United States to *Achras Sapota*, Linn., of the family *Sapotaceæ*, generally considered one of the best indigenous fruits of the American tropics. The tree is commonly cultivated, as well as naturalized, on the Florida Keys, and the fruit (Fig. 3545) is offered in south Florida markets.

Botanically the sapodilla is closely related to the mamey sapote (*Lucuma mammosa*), the ties (*L. nervosa*) and the star-apple (*Chrysophyllum Cainito*), fruits which are well known in various parts of tropical America. The tree is evergreen, stately, with a dense rounded or conical crown sometimes attaining a height of 50 to 60 feet, horizontal or drooping branches, and stiff, glossy leaves thickly clustered at the ends of the young branchlets. The wood is hard and very durable, timbers in an excellent state of preservation having been found in the Mayan ruins of Yucatan. The bark contains a milky latex known commercially as chicle,

3545. Sapodilla, the fruit of *Achras Sapota*. ($\times$ about $\frac{1}{2}$)

which is secured by tapping the trunk, and is exported in considerable quantities from Mexico to the United States, where it forms the basis of chewing-gum. The leaves are borne upon slender petioles up to 1 inch long, the blades entire or emarginate, ovate-elliptic to elliptic-lanceolate in outline, rounded-cuneate at the base and commonly obtuse at the apex, 2 to 5 inches long, glabrous, of rich green color, the midrib prominent below. The small inconspicuous flowers are produced upon short finely pubescent pedicels in the leaf-axils toward the ends of the branchlets; the calyx is composed of six small ovate-acuminate hairy sepals, the corolla white, tubular or urceolate, lobulate at the top, the stamens six, opposite the lobules, with short flattened attenuate filaments and lanceolate-acuminate extrorse anthers; staminodes six, petaloid; style clavate, hairy at the tip, the ovary ten- to twelve-celled, each cell containing one ovule.

The fruit is very variable in form, commonly round, oval, globose-depressed, or conical, and 2 to $3\frac{1}{2}$ inches in diameter. The skin is thin, rusty brown, somewhat scurfy, giving the fruit a striking resemblance to an Irish potato. The flesh is yellowish brown, translucent,

soft and melting when fully ripe, sweet and delicious, but when green containing tannin and a milky latex, so that it must not be eaten until it has become quite mellow. The seeds vary from none to ten or twelve, and are hard, black and shining, obovate, flattened, about $\frac{3}{4}$ inch long, easily separated from the pulp.

The flavor of the sapodilla is difficult of description, likened to that of a pear by some writers, and with a peculiar character common to several sapotaceous fruits. Some of the early writers were enthusiastic in praising it, the Spanish historian, Oviedo, going so far as to call the sapodilla the best of all fruits. More recently Firminger, an Anglo-Indian horticulturist, wrote that "a more luscious, cool and agreeable fruit is not to be met with in this or perhaps any country in the world," while Descourtilz says it is "melting, and has the sweet perfumes of honey, jasmin, and lily-of-the-valley." In Florida it is a general favorite, especially among residents of the keys, and in numerous other parts of tropical America it assumes considerable importance among cultivated fruits.

The tree is considered by Pittier to be indigenous in Mexico south of the Isthmus of Tehuantepec, in Guatemala, and possibly in Salvador and northern Honduras, being especially abundant in the lowlands of Tabasco, Chiapas, and the western part of Yucatan, which are the principal centers of production of chicle gum. The common name is derived from the Nahuatl word *zapotl* or *tzicozapotl*, the latter meaning "gum *zapotl*" and surviving to the present day in the precise form *chicozapote*, by which the tree is commonly known in southern Mexico; *zapotl* was the name given by the Aztecs to all soft sweet fruits. In Spanish-speaking countries the sapodilla is frequently called *nispero*, which name properly belongs to the European medlar. In the British West Indies the name *naseberry* is common. In Brazil one form of the fruit is called *sapoti*, another *sapota*. The German name for the tree is *Breipfelbaum*, the French *sapotillier*, and the Dutch *mispelboom*.

From its home in tropical America, the sapodilla has been carried around the globe, and though less commonly cultivated in the Orient than the papaya, it is grown in many regions, particularly in some parts of southern India, where, according to Macmillan, it thrives up to elevations of 3,000 feet, though in Ceylon it is seldom productive above 1,500 feet and succeeds best on the coast. In Ecuador its cultivation is said by Pittier to extend into the temperate belt at altitudes of more than 8,000 feet. Its culture in Florida is limited to the southern part of the state, approximately the section south of Palm Beach on the east coast and the Manatee River on the west. Mature trees have passed uninjured through temperatures of 28° F., according to Reasoner. A notable advantage of the tree for some parts of the West Indies is the fact that the branches are tough and not easily broken by hurricanes. In California it has not yet fruited, though in favored locations specimens have occasionally attained an age of several years without being injured by frost. Even in the tropics, however, the tree grows very slowly, and in California the cool winters greatly hinder its development. It seems probable that it may yet be fruited in protected foothill regions, but its culture in most parts of southern California is not practicable.

The soil best adapted to the sapodilla seems to be rich sandy loam, but it thrives almost equally well on light clay and on the shallow sandy soil, underlaid with soft limestone, which is found on the lower east coast of Florida. Even though grown under the most favorable conditions, the trees rarely come into bearing until six to eight years of age, if seedlings, and in some sections do not attain a greater ultimate height than 20 to 30 feet. They should not be set closer together than 25 to 30 feet, and require very little pruning, because of their close compact growth. As a general

thing the trees bear heavily, and two crops a year are frequently produced; this, with the natural variation in season among seedling trees, results in ripe fruit being found in the markets of tropical America at nearly all times of the year.

Experiments have shown that the sapodilla can be shipped very successfully and without excessive care in packing; notwithstanding the delicate texture of the skin it keeps well, and if picked while still hard can be kept in good condition for ten days or more. Shipments have been made from the Florida Keys to New York, the fruit being placed in small baskets which hold half a dozen good-sized fruits, six of these baskets being packed in a tomato-crate. For local consumption or for shipping to short distances, the common procedure in Florida is to pull the fruits from the tree and throw them into boxes or baskets, in which they are carried to market, where the ripe ones are picked out and sold from day to day. The sapodilla is used almost exclusively as a fresh fruit, usually eaten out of hand, but is sometimes utilized in Brazil and Cuba to prepare a delicious sherbet. Little is known of its culinary possibilities. Due to its lack of acidity it is doubtful whether it will lend itself to many different uses.

The sapodilla is generally propagated by seed, but the variation among seedlings in productiveness as well as in quality, size, and shape of fruit necessitates some asexual means of propagation, if the most desirable seedling forms are to be perpetuated. Horticulturists have been as dilatory in applying vegetative propagation to the sapodilla as they have with most of the other tropical fruits, but experiments in Florida have shown that it can readily be budded, using as stocks seedlings of the same species.

Seeds, if kept dry, will retain their vitality for several years, and are easily transported through the mails to any distance. They should be planted in shallow flats of light sandy soil, covering them to the depth of $\frac{1}{2}$ inch. In warm weather germination takes place within a month, and the young seedlings, after they have made their second leaves, can be potted off and carried along in pots for the first year or two, when they are ready to be set out in the open ground. If to be budded, they may be planted in nursery rows about 3 feet apart, 18 inches apart in the row. In south Florida, May has proved to be a favorable season for budding; in strictly tropical regions the work can probably be done at any time, provided the stock plants are in active growth. Budwood should be chosen from young branches which have begun to lose their greenish color and assume a brownish tinge, and should be carefully examined to see that the eyes are well developed. Shield-budding is the method used, the details being practically the same as with the mango; buds should be cut slightly more than an inch in length, and the wood removed if it comes out readily. After making the incision in the stock, the bud should be inserted and tied as promptly as possible, as the latex soon collects around the incision and renders it difficult to do the work properly. Waxed tape should be used for wrapping. After three or four weeks the stock may be headed back, and the wrap loosened, leaving the eye exposed so that it may start into growth.

Occasional seedlings produce fruits which are nearly or quite seedless; some produce fruits weighing more than a pound, while others do not weigh over two or three ounces; some are unusually prolific, or ripen their fruit at especially desirable times of the year. From such seedlings one should select the best for propagation, having in mind the characteristics which it is most desired to perpetuate.

The tree seems to be remarkably free from insect pests and fungous diseases, and in Florida requires very little attention. While fertilizers are not commonly employed, their judicious use will doubtless improve

the size of the fruit and have a beneficial effect in those frequent instances where the tree brings to maturity so many fruits that some remain very small.

F. W. POPEOE.

SAPONARIA (Latin, *soap*, the mucilaginous juice forming a lather with water). *Caryophyllacæ*. SOAPWORT. Hardy often coarse annual or perennial erect or decumbent herbs, used for borders and rockeries.

Habit either annual and resembling that of *gypsophila* or perennial and similar to that of *silene*: lvs. flat: fls. in dichotomous cymes; calyx ovoid or oblong-tubular, 5-toothed, nerves obscure; petals 5, narrow-clawed, blade entire or emarginate, the base with scales or naked; stamens 10; ovary 1-celled: caps. ovoid or oblong, very rarely subglobose.—About 40 species, Eu., principally the Medit. region and extra-Trop. Asia. Saponarias are readily established in any soil and require but little care. *S. ocymoides* is an attractive plant for the rockery or for edging. Prop. by seed or division.

A. Plants annual.

B. Calyx 5-angled.

Vaccària, Linn. (*Lýchnis Vaccària*, Scop. *Vaccària vulgaris*, Hort.). COW-HERB. Annual: lvs. ovate-lanceolate, sessile: fls. paniculate, red; calyx pyramidal, 5-angled, glabrous; bracts membranaceous, acute. July, Aug. Eu. B.M. 2290. Var. *alba*, Hort., is a white-fl. form.

BB. Calyx not 5-angled.

calábrica, Guss. (*S. multiflora*, Hort.). Annual, divaricate-branched, pilose-viscous above: lvs. opposite, oblong-lanceolate, obtuse, attenuate to the petiole, glabrous, ciliate at base: fls. in a dichotomous corymbose panicle, solitary in the axils, pale rose; calyx cylindrical, segms. obtuse; petals entire, top orbiculate, throat naked. Spring, Italy and Greece. Gn. 71, p. 78. Gt. 1:100. R.H. 1851:281. Var. *alba*, Hort. (*S. multiflora alba*, Hort.), is a form with white fls. There are horticultural forms of this species offered in the

trade under the names of *S. multiflora compacta* and *S. multiflora compacta alba*.—Seed should be sown in autumn for spring bloom or in April for summer-flowering.

AA. Plants perennial.

B. Fls. yellow.

C. Lvs. linear: stamens violet.

lùtea, Linn. Cespitose: sts. 3-6 in. high, 2-lvd.: lvs. subradical, linear, ciliate at base: fls. yellow, in dense heads; calyx round, hairy; petals linear, crenate; stamens violet. Eu.

CC. Lvs. spatulate-oblong: stamens yellow.

bellidifolia, Smith. Cespitose, glabrous: sts. 8-16 in. high: lvs. spatulate-oblong, attenuate to the petiole; cauline lvs. few, linear-spatulate: fls. yellow, sessile, congested in a small head at the top of the st.; calyx subcylindrical, teeth triangular; petals oblong-linear; stamens yellow: caps. oblong. S. Eu. to Greece.

3546. *Saponaria officinalis*. ($\times \frac{1}{4}$)

BB. Fls. rose or white.

c. The plants not caespitose.

D. St. stout, erect.

officinalis, Linn. BOUNCING BET. Fig. 3546. Perennial: sts. $1\frac{1}{2}$ – $2\frac{1}{2}$ ft. high, leafy, simple, clustered, glabrous; lvs. mostly oblong-lanceolate, 3-nerved; fls. light pink (nearly white in shady situations), in compact, corymbose, paniculate cymes; calyx glabrous, the teeth triangularly acuminate; petal-lobes obovate, entire, notched at apex. July, Aug. Eu. Var. **álbo-plèna**, Hort., is a double white-fl. form growing 2 ft. high. June–Sept. Var. **caucásica**, Hort. (*S. caucásica*, Hort.), is a double-fl. form, the fls. described as white tinted rose by some, as deeper colored than the type by others, grows 15 in. high. All summer and fall. Var. **caucásica flòre-plèno**, Hort. (*S. caucásica flòre-plèno*, Hort.), is said to have double reddish purple fls. July–Sept. Var. **flòre-plèno**, Hort., is quite double-fl., the fls. paler than the type. Var. **plèna**, Hort., grows 1–3 ft. high and lilac, rose, or white fls. July–Oct. Probably includes some of the other double varieties. Var. **ròseoplèna**, Hort., grows $2\frac{1}{2}$ –3 ft. high and rose-colored fls. July–Sept.

DD. St. slender, decumbent.

ocymoides, Linn. Sts. much-branched, 6–9 in. high, half-trailing; lvs. ovate-lanceolate, about 1-nerved, small, acute; fls. bright pink, in loose, broad cymes. Summer. Eu. B.M. 154. Gn. 60, p. 245; 78, pp. 319, 593. G. 35:841. G.M. 56:433; 57:651. G.W. 8, p. 1; 15, pp. 8, 647. Var. **álba**, Hort., is a form with pure white fls., in reality a hybrid between two forms of the species. Var. **floribúnda**, Hort., is a form more profusely fl. than the type, with lvs. small and lanceolate and fls. soft pink. Gn.W. 25:67. Var. **spléndens**, Hort., has large fls. which are a more intense rose than the type. Var. **splendidíssima**, Hort., has large deep rosy crimson fls. Var. **versícolor**, Hort., is a form in which the fls. are at first pure white later becoming rose. A cross between a white-flowering variety and var. *spléndens*. R.H. 1913, p. 303.

CC. The plants caespitose.

D. Lvs. obovate-elliptic.

depréssa, Biv. Caespitose: radical lvs. tufted, obovate-elliptic, depressed; fls. subumbellate large, rose, pedunculate; calyx very long, 5-angled, viscous-pubescent; petals bifid. Sicily.

DD. Lvs. linear.

caespitòsa, DC. Caespitose: sts. 2–3 in. high, nearly naked, fl.-bearing at the top; lvs. linear, glabrous, mostly radical, hardly denticulate; fls. rather umbellate, rose; calyx cylindrical, villous, deeply lobed, lobes

acute; petals emarginate at the top, the blade very narrow. Pyrenees. G.C. II. 15:501.

S. japónica, Hort. John Saul, is botanically unknown.—*S. pulvinaris*, Boiss. (*S. libanotica*, Hort., *S. Pumilio*, Boiss.). Densely caespitose-pulvinate; sts. low, 3–7 fl.-lvs. small, linear, subcarinate; inf. hirsute-villous; fls. bright rose.—*S. Sündermannii*, Hort., closely resembles *S. bellidifolia*, but has rather larger fls. and more of them. June.—*S. Weinmannii*, Hort., is closely allied to *S. caespitosa*, possibly only a form of it, but has paler purple fls. and a shorter calyx. Its habit is very compact and it is only 2–3 in. high.

F. TRACY HUBBARD.†

3547. White sapote.—*Casimiroa edulis*. ($\times \frac{1}{2}$)

SAPOTE, WHITE. A tropical fruit (Fig. 3547). The zapote blanco of the Mexicans (*Casimiroa edulis*), known in California and Florida as white sapote, is a fruit little cultivated outside of Mexico, but occasionally seen in the southernmost parts of the United States, in the West Indies, and even in the Orient, where it is probably of recent introduction. Horticulturally, it has been given more attention in southern California than in any other region. (P. 680.)

The tree reaches an ultimate height of 50 feet or more, with a short stout trunk, often covered with warty excrescences around the base, and a broad erect crown, sometimes spreading and dome-shaped, under favorable conditions densely foliated and of very attractive and ornamental appearance. The bark is somewhat rough, ashen gray when mature, and dotted with numerous warty light gray lenticels. The leaves are alternate, digitate, borne upon long slender petioles and composed of three to seven, commonly five, elliptical to lanceolate, acuminate leaflets, coppery when young but eventually of glossy bright green color. The small greenish flowers, less than $\frac{1}{2}$ inch in diameter, are produced in spring on short axillary panicles, and are composed of a four- or five-parted calyx, with short

acute pubescent segments, and a four- or five-petaled greenish corolla, valvate in the bud, with small oblong-elliptic acute concave petals; the stamens are as numerous as the petals and alternating with them, with short filaments and small oblong anthers; the ovary is superior, five-celled, globose, bearing at its apex a three- to five-lobed sessile stigma.

The fruit, when of a choice variety, is as large as a good-sized orange, and somewhat resembles a quince in general appearance. The tender yellow or yellowish green skin, scarcely as thick as that of an apple, surrounds the soft cream-colored pulp, of melting and delicate texture and pleasant but peculiar flavor, sweet and lacking any trace of acidity, with sometimes a touch of bitterness. The seeds, normally five in number, an inch long and half as wide, are oblong to elliptical in form, light yellow in color, reticulated on the surface; their number is frequently decreased by abortion to two or three. In the tropics the fruit ripens in July and August, in California usually not before October; it is picked when fully mature but while still hard, and must be laid away for a few days before it is mellow and ready for eating. Because of its thin skin and the delicate texture of the flesh it does not ship so readily as some other fruits, yet if taken while still hard, and carefully packed, it can be sent considerable distances. It is commonly used while fresh, and an over-indulgence in it is thought by the Mexicans to induce sleep, but it is doubtful whether there are grounds for this belief. The white sapote is popular among the Mexicans, especially in the region around Guadalajara, and is regularly found in the markets.

The hardness of the tree is attested by its behavior in southern Europe; it has fruited at La Mortola, and is cultivated at other points on the Riviera; it is also said to have fruited in the island of Jersey. In Mexico it flourishes up to altitudes of 7,000 feet, according to Von Mueller.

Although introduced to California from Mexico about 1810, it has not yet become extensively cultivated in that state, and large specimens are rather rare. One of the oldest trees, thought to have been planted about a century ago, is growing on De la Guerra Street in Santa Barbara. Although uncared for amidst the most unfavorable surroundings it bears regularly; its fruits, however, are small and practically worthless. A number of trees of considerably lesser age—most of them planted about 1895—are in bearing in various parts of southern California, and while some produce small, inferior fruits others produce large ones of delicious flavor. After it comes into bearing the tree commonly produces regularly and abundantly. It has shown itself to be remarkably drought-resistant, though it naturally succeeds much better when irrigated in the dry season. It seems to prefer a well-drained sandy loam, but thrives on heavy clay if the drainage is good, and in south Florida has done well on shallow sandy soil underlaid with soft limestone. In this latter state it has not been cultivated many years, but has come into bearing in the vicinity of Miami and seems to be at home. It has also fruited in Cuba.

Seeds should be planted as soon as possible after their removal from the fruit, in flats of light, porous soil, or singly in 3- or 4-inch pots, covering them to the depth of 1 inch. If the weather is warm, or artificial heat is provided, germination will take place within three or four weeks. The young plants should be grown in pots until 2 to 3 feet high, when they may be set out in the open ground. While young, the white sapote should be watered liberally to encourage growth, though it can get along with little water if necessary. The terminal bud should be pinched out to force the tree to branch when about 3 feet high; otherwise it is likely to make a growth of 10 to 12 feet before branching, being liable to be broken off by a severe wind.

Seedlings do not come into bearing until seven or

eight years old, and are undependable at best, many producing fruit of inferior quality. For this reason trees propagated by some vegetative means should be planted. Shield-budding is successfully practised, the method being essentially the same as with the avocado. Stock plants should be selected from young, vigorously growing seedlings, with stems about $\frac{3}{8}$ inch in diameter at the base. Budwood is taken from the ends of the branches, using fairly well-matured wood which has assumed the ashen-gray color. The buds are cut about $1\frac{1}{2}$ inches long, leaving any wood that may adhere to them, and are inserted in T-incisions, after which they are bound firmly in place with waxed tape. At the end of two to four weeks, depending upon the climate, they may be unwrapped, and then re-wrapped loosely, leaving the bud exposed so that it may start into growth, at the same time lopping back the stock to a point 3 or 4 inches above the bud. In the tropics budding can probably be done at almost any season; in California spring and summer, when the stock plants are in most active growth, are the best times.

Three named varieties have been established in California—Harvey, Parroquia, and Gillespie. Of these Harvey is the largest and probably the best; the tree is very prolific, and individual fruits sometimes measure $3\frac{1}{2}$ inches in diameter. F. W. POPENOE.

SAPROPHYTE (Greek, *rotten*, and *plant*, i.e., living on dead organic matter). A dependent, or heterotrophic, plant (whether bacterium, fungus, or higher plant) subsisting upon the humus of the soil, or dead or decaying organic materials. A holosaprophyte is a plant which lives exclusively on dead organic food. One which is only partially dependent on dead organic food and also feeds independently, as an autophyte, is appropriately called a partial saprophyte. The customary classification which includes under the term "saprophyte" all bacteria that do not subsist on living plants or animals no longer corresponds with facts. The integrity of the classification has been destroyed by the discovery of certain bacteria in the soil, as the nitrifying bacteria, which are able, even without sunlight, to appropriate the carbon dioxide of the atmosphere. Saprophytes intergrade with parasites on the one hand so closely and with autophytes on the other that the distinction of them is often difficult. For example, it is supposed that the chestnut blight (*Endothia parasitica*) was originally saprophytic, but has recently assumed a virulent parasitic development. Among the fungi we class as saprophytes all plants which live upon a dead or decaying organic substratum. Such are the baker's yeast (*Saccharomyces cerevisiae*), the mushroom (*Agaricus campestris*), and the stinkhorn (*Phallus impudicus*). Most mushrooms and toadstools are saprophytes. Some of the flowering plants possessing ectotrophic mycorrhiza (Indian pipe, *Monotropa uniflora*) and endotrophic mycorrhiza (*Neottia Nidus-avis*, *Corallorhiza innata*, *Epipogon aphyllum*, snow-plant, *Sarcodes sanguinea* and *Thesium Aseroe*) are also classed as saprophytes. A few algae are saprophytic. A cave-growing form of *Glaeotheca rupestris*, known as *var. cavernarum*, utilizes organic food and is colorless.

JOHN W. HARSHBERGER.

SARACA (from *Sarac*, the name of the genus in India). *Leguminosae*. Unarmed trees (or tall climbing shrubs?), grown in the warmhouse.

Leaves abruptly pinnate, the lfts. leathery, often few-paired; stipules small, caducous; fls. yellow, rose, or scarlet, racemose, the racemes in short very branched panicles which are often lateral; calyx-tube elongated. segms. 4, petal-like, ovate, strongly imbricated; petals none; stamens 3-9, free; ovary stipitate, ovules many; legume oblong or elongated, flat-compressed or turgid, leathery to somewhat woody, 2-valved.—About 6 species, Trop. Asia.

indica, Linn. A medium-sized tree: lfts. 6-12, oblong or oblong-lanceolate, acute or obtuse, 3-9 in. long, entire, short-petioled: fls. orange-red, fragrant, collected in compact, roundish panicles which are shorter than the lvs.; stamens usually 6 or 7, inserted on the fleshy annular ring at the summit of the calyx-tube; style long, curved: bracts red, appearing as a calyx: pod 4-10 in. long, 4-8-seeded; seeds oblong, compressed, $1\frac{1}{2}$ in. long. India and Malaya. B.M. 3018 (as *Jonesia Asoca*).—It has flowered well with greenhouse treatment at height of 4 ft. It is suitable for outdoor planting only in tropical regions. Intro. into S. Fla.

cauliflora, Baker. A shrubby tree: lfts. 10-12, rigidly subcoriaceous, the upper oblanceolate-oblong, acute, 1 ft. or more long, the lower shorter, more oblong: corymbs solitary or in pairs, nearly sessile, dense, 4-6 in. broad: fls. scarlet; stamens 7. India.—Intro. into S. Fla.

F. TRACY HUBBARD.†

SARCÁNTHUS (name from Greek words signifying *flesh and flower*, in allusion to the fleshy nature of the blossom). *Orchidaceæ*. A small genus related to *Vanda*, and owing to the smallness of the fls. seldom cult.: sepals and petals similar; labellum firmly united with the base of the column, spurred, with 2 small lateral lobes and a longer concave middle lobe: foliage and habit of *vanda*. Give plenty of water in the growing season. They should have basket cult., with fern-root, and a temperature of 65° to 85°. When at rest, give very little water and reduce the temperature to 55°. Cult. practically as for *vanda*.

teretifolius, Lindl. (*Luisia tères*, Lindl.). St. 1 ft. high, with cylindrical lvs. 2-4 in. long: raceme bearing 7-8 inconspicuous fls.; sepals and petals oblong, dull green, with red disk; labellum slipper-shaped, white, lateral lobes edged with red. Sept. China. B.M. 3571.

S. inflatus, Rolfe. Distinguished by its inflated spur, which is much longer than the segms. of the lip: sepals and petals green, with 2 dark brown stripes; front lobe of lip light yellow, side lobes white. Annam.—*S. robustus*, O'Brien. Lvs. narrowly oblong, about 6 in. long: spike few-fl'd.; fls. cream- to bluish-white, marked with claret-purple. Borneo. G.C. III. 55:21.

HEINRICH HASSELBRING.

SARCOCEPHALUS (Greek, *flesh and head*, alluding to the fleshy heads of fruit). *Rubiaceæ*. Shrubs or trees sometimes climbing, suitable for warmhouse culture or hardy in the extreme southern United States.

Branches subterete or obtusely quadrangular: lvs. opposite, rarely in whorls of 3, subcoriaceous: heads terminal and axillary; fls. whitish, pale pink or yellowish and crowded; calyx-tubes cohering, teeth 5-6, hairy; corolla narrowly funnelform, rather fleshy, 5-lobed; anthers 5, subsessile; disk inconspicuous; ovary 2-celled; syncarpium fleshy.—About 30 species. *S. esculéntus*, Afzel. A tree with long branches or often a scandent shrub 10-25 ft. or more high: lvs. elliptical, short-acuminate: fls. in terminal heads, white, pale pink or yellowish, fragrant; calyx-teeth furnished with alternating filiform-clavate appendages: fruiting head $2\frac{1}{2}$ -3½ in. diam., deep red with brown granulated surface. Trop. Afr.—Edible, the peach or country fig of the natives of Sierra Leone. *S. ovatus*, Elmer. Tree, 18 ft. high, with rigid branchlets: lvs. glabrous, leathery, ovate or elliptic, acute at the base, obtuse at the apex, $7 \times 3\frac{1}{2}$ in.: infl. capitate, peduncled; fls. reddish; calyx with clavate, pubescent and deciduous appendages; corolla glabrous, nearly ½ in. long. Philippines. Said to be intro. into Calif.

SARCOCHILUS: *Thi:asperrum*.

SARCOCÓCCA (Greek, *flesh and berry*, alluding to the fleshy fruit). *Buxaceæ*. Ornamental woody plants grown chiefly for the handsome lustrous foliage.

Evergreen glabrous shrubs: lvs. petioled, alternate, coriaceous, entire, without stipules: fls. unisexual, apetalous, in short axillary racemes with the pistillate

fls. at the base; sepals 4 or 6; disk wanting; staminate fls. with 4-6 stamens opposite the sepals; pistillate fls. with a 2-3-celled ovary with 2-3 short erect or recurved styles: fr. indehiscent, globose to ellipsoid, coriaceous or fleshy, 1-2-seeded.—Five species distributed from Cent. and W. China to the Malay Archipelago.

They are handsome evergreen shrubs with ovate to lanceolate entire lustrous leaves, rather insignificant whitish flowers in axillary clusters and red or purple berry-like fruits. *S. ruscifolia* and *S. Hookeriana* var. *humilis* have proved hardy in sheltered positions at the Arnold Arboretum, while *S. saligna* is tender. They do not seem particular as to the soil and do best in partly shaded situations. Propagation is by seeds or by cuttings which root easily.

A. Lvs. distinctly 3-nerved, caudate-acuminate.

saligna, Muell. Arg. (*S. prunifórmis*, Lindl. *Pachysandra coriácea*, Hook.). Shrub: lvs. oblong-ovate to oblong-lanceolate, caudate at the apex, broadly cuneate at the base, 2-5 in. long; petiole ½-¾ in. long: racemes about ½ in. long: fr. purple, ovoid, ⅓-½ in. long. Himalayas. B.R. 1012. I.T. 3:90.

AA. Lvs. obscurely veined.

Hookeriana, Baill. (*S. prunifórmis* var. *Hookeriana*, Hook.). Shrub: lvs. oblong-lanceolate to narrow-lanceolate, acuminate, cuneate at the base, 2-3½ in. long; petiole ¼-½ in. long: styles 3: fr. subglobose, black. Himalayas, Afghanistan. Gn. 25, p. 359. Var. *digyna*, Franch. Styles 2. W. China. Var. *humilis*, Rehd. & Wilson. Shrub, 1-5 ft.: lvs. lanceolate to oblong-lanceolate, 1¼-2 in. long. W. China.—Only the varieties seem to be in cult.

ruscifolia, Stapf. Shrub, to 6 ft.: lvs. ovate to elliptic-ovate, acuminate, rounded or broadly cuneate at the base, dark green and lustrous above, 1¼-2 in. long; petioles ½-¾ in. long: fls. in few, usually 4-fl'd. racemes: fr. subglobose, dark scarlet. Oct.-Feb. Cent. and W. China. Var. *chinénsis*, Rehd. & Wilson (*S. saligna* var. *chinénsis*, Franch.). Lvs. elliptic-ovate to elliptic-lanceolate, cuneate or broadly cuneate at the base, 1½-2½ in. long. W. China.

ALFRED REHDER.

SARCODES (Greek, *flesh-like*). *Monotropáceæ*.

S. sanguinea, Torr. (Fig. 3548), is the SNOW-PLANT of the Sierra Nevadas. It is a low and fleshy plant growing 3-12 in. high and entirely devoid of green lvs. It belongs to that strange family which comprises the fleshy and parasitic plants, of which the Indian-pipe or corpse-plant is an example. Few species are known in this family, and they are all local or rare. The snow-plant derives its popular name from its habit of shooting up and blossoming as soon as the snow melts away in the

3548. Snow-plant.—*Sarcodes sanguinea*. (X about 1)

spring. The specific name *sanguinea* refers to the blood-red color of the entire plant. The snow-plant grows at an altitude of 4,000–9,000 ft. It is the only species of the genus, and is not known to be in cult.

SARCOPÏDIUM (Greek for *flesh* and *foot*). *Orchidaceae*. Warmhouse orchids, by some referred to *Bulbophyllum* and *Dendrobium*.

Rhizome creeping, the 2-lyd. pseudobulbs usually distant on it: infl. terminal, the fls. single or in racemes; sepals and petals similar, the former usually forming a manifest chin; lip much smaller. Related to *Dendrobium*, and much like it in fl.-structure.—Species about 20, in the Malay Penins. and adjacent islands, and in the Trop. Himalayas.

âmplum, Lindl. (*Dendrobium âmplum*, Lindl. *Bulbophyllum âmplum*, Reichb. f.). Habit much like a *Bulbophyllum*: pseudobulbs oblong, ovate, or fusiform, up to 2 in. long; lvs. oblong, acute, 4–6 in. long, 2 in. broad; fls. greenish white, suffused purplish; raceme few-flid., dorsal sepal lanceolate, the lateral triangular; petals linear-lanceolate, long-acuminate; lip with round lateral lobes erect, the middle lobe rhomboid, acute. Trop. Himalayas. P.M. 7:121.

S. acuminatum, Kränzl. (*Dendrobium acuminatum*; Rolfe). Raceme few- to many-flid., lax; sepals triangular, long-acuminate, about 1½ in. long; petals of same length but narrower, yellowish white; lip with lateral lobes obovate, rounded, retuse, the middle lobe ovate-triangular, acute, the apex reflexed. G.C. III. 42:210; 46:150. G.M. 52:659. J.H. III. 59:291.—*S. Cologyne*, Kränzl. (*Dendrobium Cologyne*, Reichb. f.). Fls. usually solitary, large, 2–2½ in. across, fleshy, yellow or straw-color, purple-lined, the lip deep purple; dorsal sepal lanceolate, the lateral broader and forming a manifest angled obtuse chin; petals narrowly linear-lanceolate; lip with the ovate-acute front lobe separated by a narrow isthmus. Tenasserim and Moumein. C.O. Dend. 32. O. 1910. p. 122. J.H. III. 57:385.—*S. cymbiloides*, Kränzl. (*Dendrobium cymbiloides*, Lindl. *D. trifidum*, Lindl.). Raceme few-flid.; fls. pale yellow or straw-color, the lip yellow, suffused with rose or purple, with 2 orange spots at base of middle lobe; sepals and petals similar, acute, oblong-lanceolate, the sepals forming a very short rounded chin; lip with the middle lobe ovate-cordate, obtuse, longer than broad. Java and Philippines. G. 33:417. G.W. 14. p. 405. G.C. III. 37:15.—*S. Lobbi*=*Bulbophyllum*.—*S. Treacherianum*, Kränzl. (*Dendrobium Treacherianum*, Reichb. f.). Raceme 3–5-flid.; fls. rose, the front part of lip yellow; dorsal sepal and petals linear-lanceolate, the lateral sepals triangular, forming a round chin, all the parts acuminate; lip with middle lobe linear-oblong, acuminate, deflexed. Borneo. B.M. 6591. J.H. III. 48:187.

GEORGE V. NASH.

SARCOSTÉMA (name refers to the fleshy corona). *Asclepiadaceae*. A few small-flid. more or less succulent leafless trailing or twining shrubs of the dry parts of tropical and subtropical regions of the Old World, to which N. E. Brown refers a plant long known as a *Euphorbia*. Fls. greenish, yellowish, or white, in sessile terminal or lateral umbels; corona double, the outer part ring-like or cup-shaped and truncate or shortly lobed, the inner part of 5 fleshy erect lobes; pollen-masses solitary in each anther-cell, pendulous. *S. riminalé*, R. Br. (*Tithymalus pendulus*, Haw. *Euphorbia pendula*, Link.), grows in Trop. Afr.: trailing, twining, or bush-like, woody below, the lvs. sometimes represented by minute ovate bracts; corolla rotate or somewhat campanulate, greenish white or sulfur-colored. *S. Brunonianum*, Wight & Arn., of India, has yellow fls. The *sarcostemas* require the treatment given *ceropégias* and similar succulents.

SARGENTODÓXA (after C. S. Sargent, director of the Arnold Arboretum of Harvard University; and Greek, *dore*, glory). *Lardiabalaceae*. A woody vine, with deciduous 3-foliolate lvs. and dioecious, yellow campanulate fls. in pendulous racemes and with frs. consisting of berry-like bluish black ovoid carpels. Staminate fls. 6-merous; sepals petaloid; petals wanting; nectaries minute, suborbicular; stamens with short filaments and oblong anthers: fr. consisting of ovoid stipitate carpels each with 1 ovoid, glossy black seed. Differs from all members of the family by its numerous 1-ovuled carpels. One species in Cent.

China. A handsome vigorous-growing vine with rather large foliage and fragrant yellow fls. appearing with the leaves. Probably not hardy N. Prop. is by seed and by layers or cuttings. *S. cuneata*, Rehd. & Wilson (*Holbællia cuneata*, Oliver, partly). Climbing, to 20 ft., glabrous: lvs. long-petioled; lfts. 3, the middle one stalked, rhombic to rhombic-obovate, 3–5 in. long, the lateral ones sessile, very unsymmetrical, ovate, slightly larger than the terminal one: staminate racemes 4–5 in. long: fls. nearly ½ in. long, slender-stalked, yellow, fragrant; sepals narrow-oblong; stamen much shorter; ripe carpels ½ in. long on a stalk of about equal length. H.I. 19:1817 (excluding the fruits, which belong to *Sino-franchetia*).

ALFRED REHDER.

SARMIENTA (named after Mart. Sarmiento, a Spanish botanist). *Gesneriaceae*. A glabrous shrub, creeping or clambering over trees and rocks, to be grown in a moist greenhouse: sts. slender: lvs. opposite, rather fleshy, entire or few-toothed: fls. red, peduncled at the axils, solitary; calyx free, 5-parted, segms. narrow; corolla-tube elongate, ventricose, limb slightly oblique, lobes 5, rounded, spreading; stamens 2, posterior perfect, 2 anterior staminodea; disk obsolete; ovary superior.—One species, Chile, *S. repens*, Ruiz & Pav. Sts. slender: lvs. rather small, somewhat fleshy: fls. scarlet, axillary and solitary; calyx 5-parted; corolla-lobes 5, rounded and spreading. Summer. G.C. III. 29:303. F.S. 16:1646. J.H. III. 47:413.—It is said that it does not always thrive very well in cult. and that it should be planted in soft peat mixed with sphagnum and charcoal and either in a small pan or orchid-basket. It likes plenty of water, shade from bright sunshine and a position near the glass in a moist house.

SAROTHÁMNUS SCOPÁRIUS: *Cytisus scoparius*.

SARRACÉNIA (Dr. D. Sarrasin, of Quebec, a well-known physician and naturalist of his day, who sent *S. purpurea* to Tournefort nearly two centuries ago). *Sarraceniacae*. PITCHER-PLANT. INDIAN PITCHER-PLANT. SIDE-SADDLE PLANT. DEVIL'S BOOTS. FOREFATHER'S CUP. HUNTSMAN'S CUP. TRUMPETS. WATCHES. Pitcher-plants of swamps and savannas of the eastern United States, grown for their great oddity.

Acaulescent perennial herbs, with hollow radical lvs. usually provided with a lid or expanded blade, with a wing or keel on one side, variously colored: fl. single, terminating a naked scape, nodding, perfect, the parts mostly free and distinct; sepals and petals each 5, the latter incurved and deciduous, the sepals thick and persistent; bracts 3 beneath the calyx; stamens many; ovary globose, 5-celled, with 1 short style bearing a broadly expanded umbrella-like 5-rayed structure on the margin of which are borne the stigmatic surfaces: fr. a loculicidally 5-valved many-seeded dehiscent caps.

The family consists of three genera, *Darlingtonia*, *Heliamphora*, each with a single species, and *Sarracenia*, with seven species. The present genus is confined to North America, and almost wholly to the region east of the Mississippi. The most widely distributed species is *S. purpurea*, that extends from Florida and Alabama to Labrador and Minnesota. The others occur from southern Virginia to Florida and eastern Texas. All grow in moist or even in swampy savanna lands, in black sandy humus soil. The striking and beautiful pitched leaves, as well as the large handsome flowers, early attracted the attention of gardeners, so long ago even as three centuries. But the apparent difficulty of cultivation long prevented their becoming popular objects. The careful observations of Macbride and Mellichamp in the southern states, and later of J. Hooker in England, clearly proved that the pitched leaves are carnivorous, and that they show a remarkable microscopic structure in connection with this habit. Such has caused them to become popular objects of

study in the past three decades. All are perennial rhizomatous plants, that produce three to eight pitcher leaves in spring, and in some species (*S. Drummondii*, *S. psittacina*) another set of these, or of flat green leaves (*S. flava*, *S. Sledgei*), in autumn. When grown in sunny situations, the pitcher leaves are often richly mottled with crimson or white; sometimes even the entire leaf may be of a dark crimson-purple hue, and correspondingly attractive. Minute honey-glands occur over the exterior, which forms therefore the "alluring surface." But these are specially abundant over the inner lid surface, where they are interspersed with down-directed hairs that incline insects to move on to the upper part of the tube. So this inner lid area has been termed the "attractive surface." The upper third to half of the tube is extremely smooth, and affords little foothold for insects, which often tumble from it into the pitcher cavity. So this has been called the "conducting surface." Beneath it in *S. purpurea* is a wide glandular surface that is absent in the other species, although in some of them glands scattered

3549. Josselyn's picture, slightly reduced, of the "Hollow Leaved Lavender," 1672.

amongst fine hairs may occur. This area excretes a slightly viscous juice, which accumulates in the pitcher cavity, and which, as Mellichamp showed, readily wets and drowns any insect that falls into it. The lowest part of the pitcher in all species bears long delicate down-directed hairs that effectually prevent upward passage of insects, and so has been called the "detentive surface." The seven species vary in their carnivorous capacity, *S. flava*, *S. Sledgei*, and *S. Drummondii* being best; *S. minor* (*S. variolaris*), *S. purpurea*, and *S. rubra* being rather poor; while *S. psittacina*, with its small flat pitchers, catches relatively few. The insect prey is not digested, but its dissolved material is either absorbed by the pitcher walls, or rotting inside the decaying leaves, affords valuable nitrogenous food for the roots. But an over-abundant animal diet often causes browning and decay of the leaves, so that some gardeners have advised plugging with cotton wadding.

The pendent flowers vary in size from an inch to 3

inches across, and in color from pale lemon-yellow, as in *S. minor*, to deep crimson, as in *S. Drummondii* and *S. rubra*. Each lasts from eight to twelve days. The five spreading sepals inside three small bracteoles are more or less petaloid; the petals are large pendent banners, the stamens are numerous and discharge abundant pollen which early falls into the umbrelloid cavity of the style. The pistil consists of a five-celled ovary that is covered outside by crystalline nectar-secreting warts, and within bears many ovules; a style that expands above into a large umbrelloid structure with five marginal notches, at the base of each of which is a minute dry peg-like stigma. The entire pistil after pollination matures in about three months into a many-seeded capsule. Cross-pollination seems always to be necessary for formation of good seeds. This act, as well as hybridization of distinct species, can readily be effected if pollen from one flower that has been wetted by nectar from its ovarian surface be placed on the dry stigma of a flower on another plant. All of the seven species cross readily with each other, alike in the wild state and under cultivation, if flowers mature about the same time. Thus at various localities in western Florida and in Alabama, where the tall handsome species *S. flava*, *S. Drummondii*, and *S. Sledgei* grow, the writer has found hybrids at times to be nearly as abundant as either parent. The numerous artificial hybrids between the species, that are themselves fertile and give rise to second hybrids in which the characters of at least three parents may be blended, also testify to ease of hybridization. The seeds germinate readily in about four weeks if sown with chopped sphagnum moss on a moist sandy muck. After production of the linear cotyledons, each seedling plant forms pitcher leaves that successively increase in size till good specific characters are shown by the second year.

The larvæ of certain moths, flies, and beetles at times prey on the pitchers, while the rhizomes may be excavated and destroyed by still another type. Careful detection and destruction of the infested leaves or pieces of rhizome are recommended. Mosquitos also may breed in the liquid of the pitchers of *S. purpurea*. All of the species succeed well under cultivation if grown in pots filled with fine sandy muck, from which, while decaying, humic acid constituents are evolved. Alkaline waters are always detrimental. In this respect they require the same treatment as do other swamp or semi-swamp plants of the eastern states. They should also have a bright sunny southeastern exposure, should be kept near the glass if grown in greenhouses, and the pots should stand permanently in about an inch of water. All can endure a temperature that approaches the freezing-point in winter.

The writer has monographed the genus in Engler's "Pflanzenreich," Vol. 4, No. 110 (hft. 34, 1908). A useful synopsis, along with some helpful figures, was given by Masters in 1881 (G.C. II. 15, 16. 1881).

The sarracenias have always excited the interest of the curious, and many of the native haunts have been depleted. In his "New England's Rarities," 1672, Josselyn gives a picture (Fig. 3549) of what he calls the "Hollow Leaved Lavender," and the following account of the plant we now call *Sarracenia purpurea*: It "is a Plant that grows in salt Marshes overgrown with Moss, with one straight stalk about the bigness of an Oat straw, better than a Cubit high; upon the top standeth one fantastical Flower, the Leaves grow close from the root, in shape like a Tankard, hollow, tough, and always full of Water, the Root is made up of many small strings, growing only in the Moss, and not in the Earth, the whole Plant comes to its perfection in August, and then it has Leaves, Stalks, and Flowers as red as blood, excepting the Flower which hath some yellow admixt. I wonder where the knowledge of this Plant hath slept all this while, i. e. above Forty Years."

I. SPECIES.

A. Pitchers erect: fls. yellow or whitish yellow.

1. *minor*, Walt. (*S. variolaris*, Michx. *S. adunca*, Smith). Fig. 3550. Pitchers erect, 8–24 in. long, gradually enlarging upward, with white areoles and often brownish red streaks above; lid cucullate, incurved over orifice; wing broadest in middle, narrowed above and below: fl. 1–2 in. wide, with pale yellow petals. Moist savanna lands, S. N. C. to N. Fla. B.M. 1710. L.B.C. 9:803. Mn. 4:1. Gn. 48, p. 203.

2. *Slédgei*, Macfar. (? *S. Gronovii* var. *alata* and *S. flava* var. *crispata* of authors). Pitchers erect, 12–30 in. long, trumpet-shaped, green with purple veins above, or greenish purple throughout; lid vertical or often slightly incurved, ovate-cordate; wing as in last: fls. $1\frac{1}{2}$ – $2\frac{1}{2}$ in. wide; petals whitish yellow to yellow, often fading to white, odor agreeable. Savanna swamps from west side of Alabama and Mobile rivers to E. Texas, often covering wide areas of marshland. —Very uniform in structure, but varying in color from green to dark claret in the pitchers; often confounded in the past with *S. flava*, which does not occupy the same area. Frequently hybridizes with *S. Drummondii* in nature to form *S. areolata*.

3. *flava*, Linn. Pitchers erect, 10–34 in. long, trumpet-shaped, with prominent longitudinal veins, yellow-green to green, often crimson throat, or deep crimson throughout; lid ovate-orbicular, slightly inflexed over mouth, with strong median nerve ending in mucro; wing narrow, uniform in width: fls. 2– $3\frac{1}{2}$ in. wide, flavous yellow, odor rather pungent. Abundant over swamps and savannas, often in humus-sand that becomes dry in summer but moist in winter; S. Va. to W. Fla. B.M. 780. L.B.C. 20:1957. R.H. 1852:121. F.S. 10:1068, 1069. G.C. II. 16:11, desc. Gn. 30, p. 367; 48:202; 57, p. 326. Mn. 2:113. Var. *atrosanguinea*, Bull. (Mast.; G.C. 1881). Pitcher and lid dark crimson-claret. G.C. II. 16:13. I.H. 27:386. Not uncommon from N. to S. C. over the coastal plain region. Var. *limbata*, Bull. Lvs. medium to large, margin of operculum crimson. A rare form. Var. *máxima*, Mast. Lvs. large,

uniformly yellowish green. Frequent in S. N. C. Var. *minima*, Mast. Lvs. small, 9–12 in., pale green with purple veins over tube and lid. Occasional with the type form. Var. *ornata*, Bull. (*S. Fildesii*, Hort.). Lvs. 26–32 in., throat of pitcher and base of lid furnished with purple radiate lines. Frequent in N. and S. C. Var. *Rugelii*, Shuttl. (*S. erythropus*, Bull.). Lvs. large, 26–34 in., top of pitcher and base of lid dark crimson. Frequent throughout Ga. and W. Fla.

AA. Pitchers erect to decumbent: fls. crimson to purple-red.

4. *rubra*, Walt. (*S. Sweetii*, DC. *S. Gronovii* var. *rubra*, Wood. *S. minor*, Sweet). Pitchers erect, 6–20 in. long, slender, enlarging upward, tubular above, green to purple-veined over upper part of tube and lid; lid ovate, slightly concave and inflexed over mouth; wing rather wide, nearly uniform, from middle to top of pitcher: fls. $\frac{3}{4}$ – $1\frac{1}{4}$ in. wide, petals crimson, scent of sweet violets. Moist to dry savanna lands, usually in shade, from N. C. to N. W. Fla.; the most delicate and graceful species of the genus. B.M. 3515. L.B.C. 12:11. Var. *acuminata*, DC. Lid ovate, apex acuminate. All transitions occur between this and the type species.

5. *Drummondii*, Croom (*S. lacunosa*, W. Bartram. *S. leucophylla*, Raf. *S. undulata*, Decne. *S. Gronovii* var. *Drummondii*, Wood). Pitchers erect, 10–32 in. long, attenuate, trumpet-shaped, green below, richly purple-veined and with numerous rounded white areoles above and over lid; lid orbicular, nearly erect, margin undulate, beset within by numerous white bristle hairs: fls. on long peduncles 2–3 in. wide, greenish purple to deep purple. Often abundant in swamps and over wet savanna lands from S. Ga. through N. Fla. to E. Ala. F.S. 6:560; 10:1071, 1072. G.C. II. 15:633; 16:8. —The richest in color and most striking in aspect of the genus; well worthy of cult. in every greenhouse collection. Var. *álba*, Hort. Pitchers tall, strong, green with pure white areoles above. Occasional alongside the type in S. Ga. and W. Fla. Var. *rubra*, Hort. Pitchers attenuate, deep purple above. At times found growing with the type-species in W. Fla. The var. *undulata*, Hort., scarcely differs from the type except in the rather more undulate margin to the lid.

6. *purpurea*, Linn. The common pitcher-plant of the N. and the one on which the genus was founded. Fig. 3551. Pitchers ascending, in rosettes of 3–6, 2–10 in. long, widest toward middle, narrowed below and upward, green to dark purple; lid upright or slightly inclined outward with fine hispid hairs over inner lid or attractive surface; wing broad, prominent: fls. $1\frac{1}{4}$ – $1\frac{3}{4}$ in. wide; sepals and petals greenish purple to purple. In wet sandy muck or by swamp margins from Labrador and Minn. to N. Fla. and Ala.; flowering from fourth week in March in N. Fla. to second week of Aug. in Lab. B.M. 849. L.B.C. 4:308. F.S. 10:1076. G.C. II. 15:821. Mn. 1:81. G.L. 27:179. —Very variable in coloring from bright green in shady places to dark purple in sunny situations. According to Lodiges, writing in 1823, this species was "cultivated before the year 1640 by Tradescant, who was gardener

3551. Pitcher of
Sarracenia purpurea.
 (×½)

3550.
 Pitcher of
Sarracenia
minor.
 (×½)

to King Charles the First." Var. *heterophylla*, Eaton. Lvs. pale green; fls. yellow-green to yellow. Very rare in Mass., W. N. Y., and S. N. J.

7. *psittacina*, Michx. (*S. calceolata*, Nutt. *S. pulchella*, Croom). Pitchers procumbent in radial rosettes, 2-6 in. long, enlarging from base to hooded apex, green with purple and white veins or areoles to claret-purple throughout; apex of tube psittacoid, forming with fused lid an incurved margin to pitcher-orifice; wing narrow to wide vertical in position: fls. $\frac{3}{4}$ -1 $\frac{1}{4}$ in. wide, greenish purple to purple. Often abundant in pine-barren swamps of Ga., N. Fla., and westward to La. F.S. 7:268, desc.; 20:2063. G.C. II. 15:816. F. 1877, p. 254.—This species flourishes well under cult. when treated as a semi-aquatic, that is with its roots largely submerged in water.

II. NATURAL AND ARTIFICIAL HYBRIDS.

8. *Atkinsoniana*, Nichols. A hybrid of like parentage as *S. Stevensii*.

9. *areolata*, Macfar. (*S. Sledgei* $\times$ *S. Drummondii*). Pitcher elongate-tubular, green below, purple-veined and areolate above and over lid. Lid circular-cordate, margin somewhat undulate, with fine white hairs within: fls. 2-2 $\frac{1}{2}$ in. wide, yellowish purple.—This is a frequent hybrid wherever both parents occur near each other. It is especially abundant from near Mobile, Ala., westward for 30 miles, and thrives readily in cult. if grown like both parents with the roots largely submerged in waters that have a humic acid reaction.

10. *cantabrigiensis*, Lynch. A cross of *S. Drummondii* and *S. minor* (*S. variolaris*) that shows intermediate form and coloring between the parents. Raised by Lynch in Cambridge Botanic Garden, England.

11. *Catesbaei*, Ell. A hybrid between *S. flava* and *S. purpurea*, that is common throughout the southern states. It was first described by John Ray fully 200 years ago from specimens sent to him from this country. The writer has noted as many as 117 specimens in a forenoon near Ponce de Leon, Fla. It is easily cult., and produces pitchers and fls. that are the most striking and beautiful of the genus.

12. *Chelsonii*, Veitch. A cross of *S. rubra* with *S. purpurea* raised in the Veitch gardens, and that shows intermediate characters. The writer has once only found 2 wild examples in E. Ala., the comparative rarity seeming to be due to a difference of nearly 3 weeks in the flowering periods of the parents. G.C. II. 13:725; 15:817. I.H. 27:388. S.H. 1:189.

13. *Claytonii*, Nichols. Origin and parentage unknown; it is thus described by Nicholson: "pitchers beautifully colored vinous purple at the summit, shading to crimson."

14. *Cookiana*, Hort. Parentage unknown, said to be one parent of *S. Sanderæ*.

15. *Courtii*, Hort. One of Court's hybrids between *S. purpurea* and *S. psittacina*, and combining in exact and striking manner the details of both parents. Pitchers semi-decumbent, 6-8 in. long, greenish red becoming deep crimson upward. Orifice and incurved rim wider than in *S. psittacina*. S.H. 1:177.

16. *crispata*, André. A name of doubtful value, that seems to have been variously applied by different authors. Probably either *S. Sledgei* or a hybrid of *S. flava* with *S. minor*. The writer has gathered undoubted examples of the last-named cross near Summer-ville, S. C. Pitchers erect, green with whitish areolations above, lid broadly ovate, somewhat constricted over orifice: fls. bright yellow. I.H. 27:387. G.C. II. 15:633; 16:9.

17. *decora*, Hort. A probable cross between *S. psittacina* and *S. minor*, and so of like but more recent parentage with *S. formosa*.

18. *excellens*, Nichols. A probable hybrid between *S. minor* and the var. *alba* of *S. Drummondii*.

19. *excelsa*, Nichols. A hybrid of like parentage as *S. Moorei*, which see.

20. *exornata*, Nichols. Said to be a hybrid of *S. purpurea* with *S. crispata*.

21. *Farnhami*, Hort. A beautiful hybrid said to be a cross between *S. Drummondii* and *S. rubra*, and which combines details of both parents in pitcher and fl. The writer has collected a single wild example near Milligan, Fla., where the former parent is common and the latter is sparse.

22. *flambeau*, Hort. A hybrid of doubtful origin and parentage, cult. at Kew Gardens. Possibly a cross of *S. purpurea* with *S. minor*, and so of like origin as *S. Swaniana*.

23. *formosa*, Veitch. Pitchers ascending, intermediate between the parents *S. psittacina* and *S. minor* as to shape, color, and lid-formations. Gt. 32:317.

24. *illustrata*, Nichols. Lvs. elongate-tubular, veins becoming deep crimson upward, lid cordate, slightly acuminate, with crimson veins. Between *S. flava* var. *picta* and the hybrid *S. Stevensii*, so with 3 parts of *S. flava* "blood" and 1 of *S. purpurea*.

25. *Maddisoniana*, Nichols. A hybrid with the same parentage as *S. formosa*, but in reversed relation. Pitchers ascending, short, with dull purple veins and fine whitish areoles upward, cuculate end of tube and fused lid richly white and purple-veined.

26. *Mandaiana*, Hort. A natural hybrid with like parentage to *S. Moorei*. Over wide areas from N. Cent. Fla. to the Alabama River it is nearly always to be found wherever both parents are common. A tall handsome type with crimson throat of *S. flava* var. *Rugelii*, and the crimson and white areolations of *S. Drummondii*. It grows well under cult. First sent out by Pitcher & Manda.

27. *melanorhoda*, Veitch. A cross between *S. Stevensii* and *S. purpurea*, so with 1 part parentage of *S. flava* and 3 parts *S. purpurea*. Pitchers ascending, 6-12 in. long, widening from base to mouth, lid erect or slightly incurved with undulate margin and within showing short hairs, top of pitcher and lid crimson-green with dark crimson hispid veins, wing prominent, broadest in middle.

28. *Mitchelliana*, Nichols. (*S. Drummondii* var. *rubra* crossed by *S. purpurea*). Pitchers almost erect, funnel-shaped, pale green with red veins and whitish areoles above, lid cordate-reniform with undulate margins, and deep crimson veins around white areoles.—The artificial hybrids were sent out by Bull. The writer has got a few like plants growing wild near Bay Minette, Ala., where both parents are common.

29. *Moorei*, Mast. This, the first artificial hybrid produced, was raised by Moore of Glasnevin, as a cross of *S. flava* with *S. Drummondii*. Pitchers tall, erect, tubular, with strong veins, light green below, crimson-veined and faintly white-areolate above with usually rich crimson posterior throat area; lid crimson, and white-areolate with slightly undulate margin and hispid hairs within: fls. of a yellowish rose-to-purple color. As noted above *S. Mandaiana* is a natural hybrid of similar parentage. G.C. II. 1:702, desc.; 16:44.

30. *Pátersonii*, Hort. A hybrid raised by Patterson, orchidologist of Bridge of Allan, Scotland, and with parents like No. 28.

31. *Pöpei*, Hort. Pitchers narrow, erect, with crimson veining around mouth and ovate-acuminate lid: fls. yellowish crimson with characters intermediate between those of parents. G.C. II. 16:41. Raised by Pope of Glasnevin Garden, Dublin, between *S. flava* and *S. rubra*. It seems rarely to be produced in nature, since the former flowers about 3 weeks before the latter.

32. *porphyro-neura*, Hort. Probably a synonym of, and of like parentage with *S. Catesbaei*, and first exhibited about 1882.

33. *Sánderæ*, Nichols. An artificial cross of *S. Drummondii* var. *alba* with *S. Cookiana* of unknown parentage.

34. *Sanderiana*, Hort. A garden hybrid of *S. Drummondii* var. *rubra* and *S. Farnhami*, distributed by Sander. Cult. at Kew, and of great beauty.

35. *Stevensii*, Mast. Similar in appearance to, and of like origin as, the natural hybrid *S. Catesbaei*. Raised by Stevens, gardener at Trentham, England. G.C. II. 16:40.

36. *Swaniiana*, Nichols. Pitchers ascending to suberect, greenish crimson above with crimson veins and whitish areoles, lid ovate-cordate with slightly bilobed apex, similarly colored as extremity of tube, wing broad in middle tapered toward extremities. According to Nicholson, it is "a handsome and well-marked hybrid between *S. variolaris* (minor) and *S. purpurea*."

37. *Tolliana*, Nichols. Stated to be a hybrid of *S. Drummondii* var. *alba* and *S. flava*, but the writer considers it rather to be *S. flava* crossed by *S. purpurea*. So like *S. Catesbaei* and *S. Stevensii*.

38. *vittata*, Nichols. Between *S. purpurea* and *S. Chelsonii*. Not in general cult.

39. *Williamsii*, Mast. Of same hybrid origin and aspect as *S. Stevensii*.

40. *Willisii*, Nichols. A beautiful but complex cross of *S. Courtii* (*S. purpurea* $\times$ *S. psittacina*) with *S. melanorhoda*, that is a hybrid of *S. Stevensii* (*S. purpurea* $\times$ *S. flava*) with *S. purpurea*. It more or less combines characters from all of the 3 species-parents, and is delicately colored pale green, white, and crimson.

41. *Wilsoniana*, Nichols. Of same hybrid origin as *S. Stevensii* and others.

42. *Wrigleyana*, Veitch. Reputed to be a garden cross between *S. psittacina* and *S. Drummondii* or the converse.

J. M. MACFARLANE.

SARSAPARILLA of commerce comes from various species of *Smilax*. Wild sarsaparilla of America is *Aralia nudicaulis*.

SASKATOON. Fruit of a bush-like species of *Amelanchier*.

SÁSSAFRAS (Spanish, *Salsafra*s, Saxifraga; medicinal properties similar to those of Saxifraga were attributed to it by Spanish discoverers). *Lauræacæ*. **SASSAFRAS.** Ornamental trees grown for their handsome foliage assuming beautiful tints in autumn and for their bright-colored fruit.

Deciduous: lvs. alternate, entire or 3-lobed, slender-petioled; fls. dioecious, rarely perfect, apetalous; calyx 6-parted; stamens 9, the 3 inner ones furnished at the base with 2 stalked, orange-colored glands; staminodes 3 or wanting; anthers opening with 4 valves; ovary superior, 1-loculed: fr. an oblong-ovoid, 1-seeded, dark blue drupe surrounded at the base by the thickened scarlet calyx.—Two species, one in E. N. Amer. and one in China.

3552. Sassafras tree.

The sassafrases are handsome trees of pyramidal habit with rather large, entire or 3-lobed leaves and small yellow flowers in few-flowered racemes appearing in spring with the leaves and followed by ornamental dark blue fruits on red fleshy stalks. The native species is hardy North, while the Chinese one which is still little known in cultivation is somewhat tenderer. The

American sassafras usually affects light lands, although it may grow in clay loams. It is a desirable tree for ornamental planting on account of its handsome light green foliage, which is interesting with its varying shapes and its orange-yellow or bright red color in autumn, and on account of its decorative bright-colored fruit. It prefers, at least in the North, a warm and sunny position. It is not easily transplanted when old on account of its long tap-roots. Propagation is by seeds sown as soon as ripe; also by suckers, which are often freely produced, and by root-cuttings.

variifolium, Kuntze (*S. officinale*, Nees. *S. Sassafras*, Karst. *Laurus Sassafras*, Linn.). Figs. 3552 (winter tree), 3553. Tree, 30–60, or occasionally 90 ft. high: young branches bright green, pubescent: lvs. oval and entire, or 3-lobed almost to the middle, obtusish, silky-pubescent when young, glabrous at length, 3–4 in. long: fls. yellow, $\frac{1}{4}$ in. across, glabrous inside, without staminodes, in several-fld. racemes, umbellate when unfolding, afterward at the base of the young branchlets; staminate fls. without rudimentary pistil; staminodes wanting: fr. $\frac{1}{2}$ in. high. April, May. Maine to Ont. and Mich., south to Fla. and Texas. S.S. 7:304, 305. Em. 2:360. G.F. 7:215. Gn. 31, p. 449; 63, p. 167. G.W. 13, p. 366. Var. **albidum**, Fern. (*Laurus albidus*, Nutt.). Buds and younger branches glabrous and glaucous: lvs. glabrous. Mass. to S. C. and Ky.

Tzumu, Hemsl. (*Pseudosassafras Tzumu*, Lecomte). Tree, to 100 ft.: lvs. similar in shape to those of the preceding species, 4–8 in. long: fls. perfect, smaller, pubescent inside, with 3 staminodes alternating with the 3 glandular stamens; the staminate fls. with rudimentary pistil: otherwise like the preceding species. Cent. China. H. I. 29:2833.

ALFRED REHDER.

SATUREIA (the old Latin name used by Pliny), also spelled *Satureja*. Syn., *Calamintha*. *Labiatae*. SAVORY. Hardy aromatic herbs and subshrubs, grown in borders for their flowers and also as pot-herbs.

Leaves entire, narrow and small or toothed, or broad and larger: floral whorls either axillary or in terminal spike-like racemes; calyx campanulate-tubular or tubular, rarely campanulate, 10–13–rarely 15-nerved, 5-toothed, sometimes 2-lipped; corolla-tube short or long, exerted, upper lip flat, entire or emarginate, lower lip expanded, 3-cleft, with flat lobes, the midlobe usually larger and emarginate; stamens 4: nutlets ovoid,

smooth.—About 160 species in the warmer regions of both hemispheres.

A. Plants annual.

Ácinos, Scheele (*Calamintha Ácinos*, Clairv.). Annual, herbaceous, about 6 in. high: sts. suberect, branched, pubescent or villous: lvs. ovate, rather obtuse, base narrowed, subserrate, green on both sides; floral lvs. similar, exceeding the fls.: floral whorls about 6-fld., distant; calyx 3–4 lines long, deeply 13-striate, hispid; corolla purple-blue, scarcely exceeding the calyx. Eu., Caucasus.—Escaped from cult. in N. Amer.

horténsis, Linn. (*Calamintha horténsis*, Hort.). SUMMER SAVORY. Annual herb, pubescent: sts. erect, about 6 in. high or a little more: lvs. oblong-linear, acute, base narrowed to a short petiole; floral lvs. similar: floral whorls laxly somewhat 6-fld., in dense interrupted spikes; calyx scabrous-hispid on the nerves; corolla sparsely pubescent outside, scarcely exceeding the calyx. Eu., and widely escaped from cult.

AA. Plants perennial.

B. Lvs., at least some of them, subrotund.

alpina, Scheele (*Calamintha alpina*, Lam.). Perennial, diffuse, pubescent or villous: sts. much branched and somewhat woody at base, about 6 in. high: lvs. petioled, subrotund or ovate, scarcely serrate; floral lvs. sometimes narrower, about equalling the calyx: floral whorls 4–6-fld.; calyx subsessile, purplish; corolla larger, purple, throat strongly dilated. Medit. region.

córsica, Caruel (*Thymus córsica*, Pers. *Calamintha córsica*, Benth.). Subshrub, perennial, small, much-branched, rather glabrous: lvs. scarcely 2 lines long, petioled, subrotund, entire, usually glabrous, sometimes pilose; floral lvs. similar: floral whorls on flowering branches, 1 or 2; calyx subsessile; corolla light purple. Corsica.

BB. Lvs. ovate, oblong-linear or spatulate.

montána, Linn. (*Calamintha montána*, Lam. C. *officinális*, Moench). WINTER SAVORY. Subshrub, glabrous or slightly scabrous-pubescent: sts. woody at base; branches erect or ascending, 6–12 in. high: lvs. oblong-linear, acute or inferior spatulate or cuneate, obtuse; upper and floral lvs. narrower: floral whorls many-fld., laxly secund, approximate in a spike or raceme; calyx campanulate, 10-nerved or rarely obscurely 13-nerved; corolla white or purplish. Eu., N. Afr., and widely cult.

vària, Webb & Berth. (*Thymus ericæfolius*, Roth. *Micromeria vâria*, Benth.). Subshrub, pubescent or villous: sts. procumbent, much branched, branchlets ascending, canescent-tomentose, rarely glabrous: lvs. sessile, lower ovate, upper lanceolate, fascicled at the axils, all obtuse, somewhat canescent beneath; floral lvs. minute: floral whorls 2–10-fld.; calyx erect, slightly pubescent, purplish; corolla scarcely exceeding the calyx. Canary Isls.

S. grandiflora, Scheele (*S. grandiflora*, Moench.) Herbaceous perennial: lvs. ovate, serrate: sts. decumbent, branching from the base: fls. in axillary whorls, quite large, $1\frac{1}{2}$ in. long, with a straight tube; upper lip flattened, purple. June, July.

F. TRACY HUBBARD.

3553. Sassafras variifolium. ($\times \frac{1}{3}$)

SATYRIUM (Greek, *satyr*; *Satyrion* was the name given by Dioscorides to one of the orchids). Syn., *Diplécthrum*. *Orchidaceæ*. Terrestrial orchids with tuberous roots, some of the species adapted to the warmhouse, others to the coldframe.

Tuber undivided: lvs. few, on the lower part of the st., rarely many at the sides of the tall st.: fls. medium-sized or rather large, in often densely fld. spikes; bracts membranaceous or somewhat leafy, sometimes imbricate in the young spike and often strongly reflexed, in a dwarf species overlapping the fls.; sepals free, rather similar to the petals; labellum erect, broad-concave, galeate or cucullate undivided: caps. erect, oblong, not beaked.—About 125 species, India, Mascarene Isls., Trop. and S. Afr. Most of the species, of which several are more or less commonly cult. abroad, succeed well in a coldframe, in a compost of turfy peat, fibry loam and sand with plenty of drainage. Prop. by division of roots, made as fresh growth is commencing.

carneum, R. Br. One to 2 ft. high: sts. stout: lvs. 2, radical, subsessile, ovate or orbicular-ovate: scapes with several ovate or spathaceous sheaths; spikes oblong, 3–8 in. long, dense, many-fld.: fls. large, pink or rose-colored; sepals and petals united at base, odd sepal lanceolate-oblong, obtuse, lateral sepals larger; petals elliptic-oblong; lip cucullate. S. Afr. B.M. 1512. G.C. III. 4:697. G.W. 2, pp. 349, 350.

nepalense, Don. St. 6–30 in. high, usually very stout: lvs. few, oblong to linear-oblong, 4–10 x 2–4 in., rather fleshy, sessile: spike 1–6 in. long, densely fld.; bracts oblong or lanceolate, much larger than the fls.: fls. fragrant, white to rose-pink; sepals linear-oblong, obtuse; petals rather narrower, lip superior, broadly ovate, concave and strongly keeled on the back. Himalayas to Ceylon and Burma. B.M. 6625. Var. *ciliatum*, Hook. f. (*S. ciliatum*, Lindl.), is a small plant with the spurs hardly longer than the sepals. Himalayas.—This species and its variety require greenhouse heat.

spheerocarpum, Lindl. About 12–18 in. high: sts. stout: lvs. 2–4, suberect, ovate-oblong or elliptic-oblong, somewhat fleshy: scapes with a few large spathaceous sheaths; spikes 2–8 in. long, dense and many-fld.; bracts ovate or ovate-lanceolate: fls. large, white, variably blotched and sometimes suffused with red; sepals and petals united nearly to the middle, lanceolate-oblong, more or less recurved, lateral sepals broader than the other segms., lip cucullate, broadly elliptic-ovate. S. Afr. B.M. 7295.

S. aurantiacum, T. S. Ware, is a species with broad lvs., long and compact fl.-spike and rich orange fls. Probably of garden origin.

F. TRACY HUBBARD.

SAUROMATUM (*saura*, lizard; referring to the spotted flower). *Araceæ*. Perennial herbs, with unisexual naked flowers, grown for ornament.

Tubers bearing a single pedate lf. one year, the next year lvs. and fls.: petioles cylindrical, spotted below; blade pedately parted: peduncle short: spathe soon withering, its tube oblong, swollen at the base, more or less connate, its blade or banner long-lanceolate, black-purple, variously spotted.—Species 6, India, Java, and Trop. Afr. The following are hardy bulbous plants, with large and curious fls. The fls. are produced from Jan. until June, and the bulbs have kept well in a dry state for a year. There is little danger of the bulbs shriveling or rotting. Plant them 6 in. deep in pots or in the garden. Easily managed by the amateur.

guttatum, Schott. Petioles 3 ft. long, not spotted; lf.-segms. 6–8 in. long, 2–3 in. wide, the lateral smaller: spathe-tube green on the back, 4 in. long, the upper third narrowed; blade 12 in. long, 2 in. wide below, gradually narrowing above, olive-green on the back, yellowish green within, with dense, irregular black-purple spots. Himalayas. J.F. 1:12. B.R. 1017 (as *Arum venosum*).

venosum, Schott (*S. similense*, Schott.). Petioles spotted, 3½ ft. long; lf.-segms. 8–10 in. long, 4 in. wide, the lateral smaller: spathe-tube 3–4 in. long, purple on the back: blade 14–16 in. long, 3 in. wide below, about 1 in. wide from the middle to the apex, purple on the back, yellow within and with crowded oblong purple or black spots. Himalayas. B.M. 4465 and F.S. 13:1334 (both erroneously as *S. guttatum*).

S. brevipes, N. E. Br. Petiole up to 15 in. long, rose, the segms. of blade 5–9, 4–6 in. long, narrowly linear-lanceolate, caudate-acuminate: spathe shortly stalked, the tube swollen, 1½ in. long, pale yellowish green, faintly rose-spotted, the limb narrow, convolute, twisted, arching, 4–6 in. long, pale greenish or rose, bright red at throat; spadix as long as spathe, slender, rose below, orange above. Sikkim. B.M. 7940.

JARED G. SMITH.

GEORGE V. NASH.†

SAÛROPUS (Greek for *lizard foot*). *Euphorbiaceæ*. Tropical shrubs rarely cult.: lvs. alternate, simple: fls. in axillary clusters, apetalous, sepals imbricate; no rudiment of a pistil in the staminate fls.; disk absent from the pistillate fls.; styles almost entire; ovules 2 in each of the 3 cells of the ovary: fr. more or less fleshy.—About 20 species of Trop. Asia and South Sea Isls. Related to *Phyllanthus*. *S. albicans*, Blume, occurring in many varieties from Ceylon to the Philippines, has edible fr. and has been in cult. in Eu.

J. B. S. NORTON.

SAURÛRUS (Greek, *lizard's tail*, referring to the curve of the spike of fls.). *Saururaceæ*. **LIZARD'S TAIL**. Perennial marsh herbs, suitable for the bog-garden.

Erect: lvs. heart-shaped, converging-ribbed, petioled, without distinct stipules: fls. crowded in a slender-naked-peduncled terminal spike or raceme; perianth none; stamens mostly 6 or 7, hypogynous: fr. somewhat fleshy, wrinkled, of 3–4 carpels united at base and indehiscent; seed usually solitary.—Two species, one in N. Amer., the other in Asia.

3554. *Saururus cernuus*. (×¼)

cernuus, Linn.

LIZARD'S TAIL. Fig. 3554. Height 2–5 ft.: lvs. cordate, acuminate: fls. white, fragrant, in a spike which is nodding at the end; bract lanceolate; filaments long and capillary. In swamps and shallow water, Conn. to Ont., Minn., Mo., and southward. June–Aug. B.B. 1:482.

Lourèirii, Decne. (*S. chinensis*, Hort.). Perennial, from a strong rhizome: sts. stout, 12–16 in. high, round below, angled above: lvs. alternate, petioled, cordate-based, ovate, acute, 4–5 in. long, bright green: spikes cylindrical, 4–5 in. long, axillary in the uppermost lvs., which turn yellowish white at the time of flowering; filaments very short. China and Japan. R.H. 1908, p. 395.

F. TRACY HUBBARD.

SAUSSUREA (named after Theodor de Saussure, 1767–1845, or for his father, Horace Benoit de Saussure, 1740–1799). *Compositæ*. Annual, biennial, or perennial, glabrous or tomentose herbs of various habit, sometimes planted in the garden for ornament.

Leaves unarmed, alternate, entire, toothed, pinnatifid or pinnatisect: heads narrow or broad, sometimes crowded on the dilated top of a simple st., peduncled, or sessile, solitary, corymbose or panicle; fls. purple or bluish, all perfect and similar, tube slender, limb narrow 5-cleft; involucre ovoid-oblong, globose or hemispheric, bracts not spinescent: achenes glabrous, oblong, 4-ribbed.—About 200 species, temperate regions of Eu., Asia, and N. Amer., mostly in the mountains. *S. gossypiphora*, Don. Perennial, densely long white or yellowish matted woolly: st. 6-12 in. high, hollow, clavate, often 4 in. broad at top: lvs. sessile, linear, remotely toothed or runcinate-pinnatifid: heads very many, cylindric; involucre-bracts linear-oblong, shining: achenes narrowly obovoid. Himalayas and China. G.C. III. 51:85. *S. leucoma*, Diels. Plant 4-9 in. high: lvs. basal, narrowly pinnate, upper almost linear, the blade being entirely sacrificed to the development of the abundant cottony tomentum in which practically the whole plant is smothered, the fl.-heads alone are free of it and form a compact mass 2-3 in. diam. China. G.C. III. 51: suppl. Feb. 10. *S. Veitchiana*, Drumm. & Hutchins. Herb. 2-3 ft. high, with about 2-5 leafy scapes from a tufted crown: fl.-sts. rigid, floccose upward: lvs., the lowest, 10 x 2 in., oblong-linear, green above, loosely hairy below; the upper ovate-lanceolate; bracts bluish-pink or purplish: heads nearly ovoid, over 1 in.; florets deep purple. China. B.M. 8381. G.C. III. 50:85. F. TRACY HUBBARD.

SAVORY. Sweet-herbs.

Summer savory is *Satureia hortensis* of the *Labiatae*. Cultivated in kitchen-gardens for its aromatic green parts, which are gathered in midsummer for flavoring meat, dressings, and other culinary preparations. The slender, erect, branching, herbaceous stems, 10 to 12 inches tall, bear soft narrow green leaves and in summer clusters of pink, purplish or white flowers, which are followed by brown ovoid seeds whose vitality lasts three years. Propagation is by means of seed, which is sown in drills 12 to 18 inches apart in April or May in light, mellow, well-drained loam of moderate richness. When 2 to 3 inches tall the plants are thinned to 5 or 6 inches asunder, or for early crop they may be transplanted from hotbeds sown in March.

Winter savory (*S. montana*) is a hardy European perennial species, having much the qualities of the annual, but with woody, slender, very branching stems 12 to 16 inches tall, narrow, very acute leaves, white, pink or lilac flowers and brown seeds, whose average vitality is three years. It may be managed like thyme.

M. G. KAINS.

SAXEGÓTHÆA (in honor of Prince Albert of Saxe-Coburg-Gotha, consort of Queen Victoria). *Taxaceæ*. An evergreen tree, native of Chile, similar in habit and foliage to the yew: monocious, staminate fls. in cylindrical spikes clustered at the end of the branchlets; pistillate fls. solitary at the end of branchlets: fr. a small stalked irregularly subglobose cone with the scales terminating in spiny flattened points; seeds ovate, keeled, lustrous, brown. The plant is not hardy North and it is doubtful whether it is in cult. in this country; it is of slow growth and has no particular ornamental merit, but botanically it is very interesting. Prop. is by intro. seeds or by cuttings treated like those of taxus; it also may be grafted on taxus or podocarpus. *S. conspicua*, Lindl. Tree, to 40 ft., with whorled drooping branches: lvs. linear or linear-lanceolate, spiny-pointed, at the base abruptly contracted into a short decurrent stalk, dark green above, with 2 broad white lines beneath, $\frac{1}{2}$ -1 in. long: staminate spikes $\frac{1}{4}$ in. long: fr. about $\frac{1}{2}$ in. across. J.H.S. 1851, pp. 260, 261. F.S. 7, p. 84. J.F. 2, pp. 69, 71. B.H. 6, p. 309 (pl. 75). I.H. 1, p. 16. G.C. III. 2:684; 5:782.

S. gracilis, Hort. = *Podocarpus nubigena*.

ALFRED REHDER.

SAXIFRAGA (Latin, *rock* and *to break*; said by some to refer to the fact that many of the species grow in clefts of rock, by others to the supposition that certain species would cure stone in the bladder). Including *Bergenia* and *Peltiphyllum*, genera which are maintained as distinct by Engler in his last treatment of the group. *Saxifragaceæ*. SAXIFRAGE. ROCKFOIL. Chiefly perennial herbs, but a few species are annual and a few others biennial, while some others are subshrubby; useful for border planting, rockeries, and alpine gardens, and much prized by fanciers, particularly abroad.

Plants usually with more or less developed caudices which are either above or below ground: lvs. commonly clustered at the base and most often alternate on the sts., very variable in shape: infl. paniculate, corymbose, racemose or solitary: fls. as a rule not large, white, yellow, red, pink, or purple; calyx either free from or partly adnate to the base of the ovary, the tube short or elongated, 5-cleft or 5-parted; petals usually equal but occasionally decidedly unequal; stamens 10, rarely 5: fr. a 2-beaked, 2-celled caps. opening down or between the beaks, or sometimes 2 almost separate follicles; seeds numerous.—About 400 species from a horticultural viewpoint or approximately 250 botanically speaking. Temperate (principally alpine) and northern boreal regions, rare in Asia, very few in S. Amer. and lacking in Austral., S. Afr., and the Pacific islands. In preparing the following treatment of the genus and in the arrangement of species, Engler, in Engler & Prantl's *Pflanzenfamilien*, has been followed with the exception above mentioned, while the specific delimitation is largely based on Engler's *Monographie der Gattung Saxifraga*, 1872, with cultural and other horticultural information drawn from Irving & Malby's *Saxifragæ*. The true saxifragæ, so-called (excluding *Bergenia* and *Peltiphyllum*), have been separated into several genera at different times. The horticultural species mentioned in this treatment which are native of N. Amer. have been divided among the following genera: *Saxifraga*, *Muscaria*, *Chondrosea*, *Micranthes*, *Spatularia*, *Leptasea*, *Heterisia*, *Peltiphyllum* and *Antiphylla*. See Small in N. Amer. Fl., vol. 22, pt. 2, 1907.

Saxifragæ are various in habit and stature, but they are mostly low and spreading with rosulate or tufted root-leaves. Most of the species in cultivation are grown as rock-garden plants, although the large-leaved members of the *Megasea* or *Bergenia* section are sometimes used as border plants. Owing to the small attention given to rock- and alpine-gardening in America, the saxifragæ are little known to our horticulturists. Most of them are abundantly hardy as to frost, but are likely to suffer from the dryness and heat of the American summer. Partial shade in summer is essential for the best results with most of the species. In winter the stools should be given ample covering of leaves. The most useful kinds for this country are the species of the *Megasea* section. These are low plants of bold habit, and are admirably adapted for rockwork and for spring forcing under glass. Fig. 1819, Vol. III, shows a clump of these plants in the lower left-hand corner.

The alpine species are mostly dwarf plants with more or less persistent foliage. Many of them, as *S. oppositifolia*, make dense moss-like mats; others, of which *S. aizoon* may be taken as a cultural type, produce a dense rosette of leaves at the surface of the ground, from which arises a flower-scape. Some of these forms are very interesting because of the vari-colored or silvery effect produced by natural incrustations of lime on the leaves, particularly on the leaf-edges. Give shade.

Most saxifragæ make stolons and offshoots freely, and by these the plants are easily propagated; they are also increased by division. Some make bulblets and multiply in this manner.

The number of species of saxifrage cultivated abroad in rockeries and alpine-gardens is very large and there are many fanciers who have made very large collec-

CIII. Greenhouse group of parent and hybrid *sarracenias*.

- 1, *S. purpurea*; 2, *S. psittacina*; 3, *S. Stevensii* × (*S. flava* × *S. purpurea*); 4, *S. Chelsonii* × (*S. purpurea* × *S. rubra*); 5, *S. rubra*; 6, *S. Sledgei*; 7, *S. Moorei* × (*S. flava* × *S. Drummondii*); 8, *S. minor*; 9, *S. areolata* × (*S. Drummondii* × *S. purpurea*); 10, *S. Drummondii*; 11, *S. flava*. Between 8 and 10 is a hybrid of *S. Mitchelliana* × (*S. Drummondii* × *S. purpurea*).

tions of them. The following account has attempted to include those species which are in more general cultivation, although there are numerous others which occur in some of the collections, and it includes the better known hybrids and certain seedlings. A large part of these species are either very rare or lacking in American gardens. Very few of the species have been modified to any extent under domestication.

KEY TO THE SECTIONS.

- A. *Lvs. glandular-punctate, usually large and thick; the petiole sheathed at the base.*
I. BERGENIA. Species 1-5.
AA. *Lvs. not glandular-punctate (sometimes pitted), usually not large; the petiole not sheathed at the base.*
B. *Seeds spherical: the lvs. brown-striate.*
II. CYMBALARIA. Species 6, 7.
BB. *Seeds fusiform or elongated: the lvs. usually not brown-striate.*
C. *Pits absent on the lvs. (some species of Section Trachyphyllum have 1 pit at the apex of the lf.): lime secreted.*
D. *Plants annual or biennial: caudicles absent.*
IV. TRIDACTYLITES. Species 10.
DD. *Plants perennial (No. 20 may occasionally be biennial): caudicles present.*
E. *Caudicles subterranean.*
F. *The caudicles annual, biennial, or perennial; the secondary shoots with shortened internodes, bulbous and separating from them with age.*
V. NEPHROPHYLLUM. Species 11-13.
FF. *The caudicles perennial; the secondary shoots permanently attached to them.*
G. *Lvs. peltate.*
XV. PELTIPHYLLUM. Species 100, 101.
GG. *Lvs. not peltate.*
H. *Caps. somewhat inflated, splitting above the middle.*
VII. BORAPHYLLA. Species 37-47.
HH. *Caps. not inflated, splitting below the middle.*
I. *Fls. white.*
III. MISCOPETALUM. Species 8, 9.
II. *Fls. yellow.*
IX. HIRCULUS. Species 52-54.
EE. *Caudicles above ground.*
F. *Petals unequal: plants mostly with runners.*
VIII. DIPTERA. Species 48-51.
FF. *Petals equal.*
G. *Ovary more or less adnate with the calyx-tube.*
H. *Lvs. herbaceous, undivided or lobed.*
VI. DACTYLOIDES. Species 14-36.
HH. *Lvs. rigid, withering, commonly setose, not herbaceous.*
X. TRACHYPHYLLUM. Species 55-62.
GG. *Ovary entirely free.*
XI. ROBERTSONIA. Species 63-65.
CC. *Pits present on the lvs.: lime secreted.*
D. *Secondary shoots separating early from the caudicles, more or less stoloniferous, their apex with a rosette of lvs.*
XII. EUAZOONIA. Species 66-77.
DD. *Secondary shoots remaining attached to the perennial caudicles.*
E. *The lvs. alternate.*
XIII. KABSCHIA. Species 78-96.
EE. *The lvs. decussately opposite.*
XIV. PORPHYRION. Species 97-99.
XVI. HYBRIDS. Species 102-135.

Unkeyed

Section I. BERGENIA (MEGASEA).

- A. Margin of lf. not ciliate, but more or less undulate or crenate: lvs. not pubescent.
 B. Scape and infl. glabrous.
 C. Lvs. orbiculate-cordate..... 1. *cordifolia*
 CC. Lvs. obovate to long-obovate, more or less cuneate at the base..... 2. *crassifolia*
 BB. Scape and infl. pubescent..... 3. *purpurascens*
 AA. Margin of lf. ciliate: lvs. sometimes pubescent.
 B. Base of lf. distinctly cordate although narrow: calyx glabrous..... 4. *ligulata*
 BB. Base of lf. usually narrowed to the petiole: calyx pubescent or at least puberulent..... 5. *Stracheyi*

1. *cordifolia*, Haw. (*Megasea cordifolia*, Haw. *Bergenia cordifolia*, Sternb.). Twelve to 20 in. high, robust: lvs. orbiculate-cordate, broad and fleshy, margin undulate-serrate, glabrous, shining; petioles long and thick: infl. a short, thick, angled, shiny scape: fls. clear rose, in dense nodding cymes partly hidden in the lvs.; pedicels short and thick; calyx-lobes short and broad; petals roundish. March-May. Siberia. Gn.M. 3:136.—Closely allied to *S. crassifolia* but differing in the broader cordate-based lvs. and in the rounder petals. Var. *alba*, Hort. (*Megasea cordifolia* var. *alba*, Hort.). Fls. delicate blush-pink, not true white. Var. *grandiflora*, Hort. Said to be unusually handsome in fl. and fl. Var. *purpurea*, Hort. (*S. purpurea*, Hort. *Megasea cordifolia* var. *purpurea*, Hort.). Lvs. smooth and coarsely serrate, the panicles larger than the type and carried well above the lvs.: petals broad rounded and deep reddish purple. Var. *rosea*, Hort. (*Megasea cordifolia* var. *rosea*, Hort.) has been offered.

2. *crassifolia*, Linn. (*S. cuneifolia*, Hort., not Linn. *S. sibirica*, Hort., not Linn. *Megasea crassifolia*, Haw. *Bergenia crassifolia*, Fritsch). Fig. 3555. Six to 16 in. high, stout: rhizomes woody: lvs. obovate to long-obovate, large and thick, narrowed at the base and decurrent on the petiole, margin serrate to nearly entire, apex obtuse, glabrous, shining: infl. a fairly tall, angled, reddish or purplish scape: fls. deep rose, lilac or purplish, in dense panicles, elevated above the lvs.; calyx-lobes oblong, obtuse; petals elliptic-oblong. March-May. Altai to Mongolia. B.M. 196. G.M. 34:67. Mn. 10, p. 74.—*S. Van Houttei*, Hort., is only a variation of this species, with lighter pink fls. Var. *orbicularis*, Hort. (*S.*

3555. Saxifraga crassifolia.

orbicularis, Hort. *Bergenia orbicularis*, Stein. *Megasea orbicularis*, Hort.). A small-growing form with broad rather rounded lvs., a branching habit and an abundance of light rosy fls. which are borne well above the foliage.

3. *purpurascens*, Hook. f. & Thom. (*Megasea purpurascens*, Hort. *Bergenia purpurascens*, Engl.). Three to 12 in. high: lvs. roundish-obovate to short-oblong, 2-3 in. long, base somewhat cordate, margin more or less undulate, glabrous: infl. a scape about 1 ft. high, purple, this and the pedicels very pubescent: fls. deep purple, nodding, in few-fl. corymbose panicles; calyx-lobes very obtuse; petals $\frac{3}{4}$ in. long, obovate-oblong, sometimes long-clawed: fr. elliptic-lanceolate, erect. June. Sikkim (India), 10,000-15,000 ft. B.M. 5066. H.F. II. 1:172. B.H. 9:1. F.S. 14:1401.—A very handsome species because of its purple scapes and fls. and the beautiful purple-and-crimson autumnal foliage. Succeeds best in a rather sheltered spot.

4. *ligulata*, Wall. (*Megasea ligulata*, Hort. *Bergenia ligulata*, Engl.). One foot high, stout: radical lvs. large, orbicular or obovate, 2-12 in. diam., base cordate, mar-

gins entire but ciliate, both surfaces glabrous: infl. an erect naked scape, this and the pedicels and calyx glabrous: fls. white, rose or purplish, campanulate in nodding 1-sided racemes; calyx-lobes ovate, not narrowed at base; petals $\frac{1}{2}$ -1 in. long, orbicular and clawed: fr. subglobose, cernuous. March-May. Himalayan region. B.M. 3046 ("the sepals too acute and the leaves too undulate," according to Hooker). L.B.C. 8:747. R.H. 1868:270. J.H. III. 69:136. Gn. 62, p. 25; 76, p. 204.—Not perfectly hardy at Boston. Sometimes erroneously written *S. lingulata* which is a very different species (No. 67).—*S. ornata*, Decne. (*Bergenia ornata*, Stein), is said to have large coriaceous, persistent lvs., fleshy sts., and large rose fls. in cymes. Apparently does not possess any character to distinguish it from *S. ligulata* except the fls. are a shade lighter in color. Var. *ciliata*, Hook. (*S. ciliata*, Royle. *S. thysanodes*, Lindl. *S. Stracheyi* var. *thysanodes*, Hort. *Megasea ciliata*, Haw. *M. ligulata* var. *ciliata*, Hort. *Bergenia ciliata*, Stein). Lvs. hirsute on both surfaces, margins strongly ciliate. B.M. 4915. B.R. 32:33 (as *S. thysanodes*). G.C. III. 5:365. F.E. 16:472. Var. *Leichtlinii*, Hort. (*S. Leichtlinii*, Hort. *Megasea Leichtlinii*, Hort.). Grows about 1 ft. high and has large crimson lvs. and rose-colored fls. Var. *rosea*, Hort., is a form with rose-colored fls. Var. *rubra*, Hort., is an early-flowering, low form with red or red-purple fls. Var. *speciosa*, Hort. (*S. speciosa*, Hort., not Doerfl. & Hayek. *Megasea speciosa*, Hort.). Lvs. broadly ovate, leathery: fls. crimson or deep rosy crimson. Gn. 71, p. 250. J.H. III. 60:393.—By some this is thought to be a garden hybrid *S. ligulata* $\times$ *S. crassifolia*.

5. *Stracheyi*, Hook. f. & Thom. (*S. unguiculata*, Hort., not Engl. *Megasea Stracheyi*, Hort. *Bergenia Stracheyi*, Stein). Fig. 3556. Six inches to 1 ft. or more high: lvs. obovate, usually not cordate at base, margin subentire, ciliate or crenate-serrate, both surfaces glabrous: infl. a scape about 1 ft. high with the pedicels and calyx pubescent or puberulous: fls. blush-pink to rose (sometimes yellow), in broad branching panicles $\frac{3}{4}$ -1 in. diam.; calyx-lobes oblong. March. Kashmir, 8,000-14,000 ft. B.M. 5967(?). G.M. 39:233. J.H. III. 32:281. G. 12:337.—More hardy than *S. ligulata*. Var. *alba*, Hort. (*S. afghanica*, Aitch. & Hemsl. *S. afghanistanica*, Leicht. *Megasea afghanica*, Hort.). A snowy white-fl. form, the lvs. bronzy or ruby-brown. Gt. 35:1228. G. 31:751. Var. *Milesii*, Hort. (*S. Milesii*, Hort. Leicht. *Bergenia Milesii*, Stein. *Megasea Stracheyi* var. *Milesii*, Hort.). Differs from the type in having longer lvs. (9-12 $\times$ 4-5 in. at the middle): fls. white; petals distinctly clawed. March. Himalaya. Var. *Schmidtii*, Hubb. (*S. thysanodes*, Hort. Haage & Schmidt, not Lindl. *S. Schmidtii*, Regel. *Bergenia Schmidtii*, Hort.). Lvs. ovate, base equally rotundate or attenuate to the petiole, margin coarsely crenate and then dentate, the teeth cuspidate-ciliate: fls. panicked, similar to those of *S. crassifolia*. Himalaya. Gt. 27:946. B.R. 29:65 (as *S. ciliata*).

Section II. CYMBALARIA.

- A. Lower lvs. 7-11-lobed; the lobes acute.. 6. *Cymbalaria*
 AA. Lower lvs. 5-7-lobed; the lobes obtuse or very shortly apiculate..... 7. *Huetiana*

6. *Cymbalaria*, Linn. Annual or biennial: sts. nearly erect or somewhat flexuous, branched, 3-12 in. high: lvs. tender, with age brown-striate on both surfaces, margin glandular-pilose; lower lvs. reniform, cordate or truncate at base, 7-11-lobed, lobes broad-acute; upper lvs. short-petioled, 3-7-lobed, base attenuate: infl. cymose with elongated axis; pedicels long, 1-fl., these and the calyx short glandular-pilose: fls. yellow; calyx-lobes oblong, acute; petals oblong, base cordate, distinctly clawed, 3 times the length of the calyx-lobes. May-Aug. Caucasus and Asia Minor.—The lvs. are light green, glossy and ivy-like. It sows itself

abundantly and is suitable for moist spots in rock-work or along streams. Some, possibly much, of the material cult. as *S. Cymbalaria* is really the closely allied *S. Huetiana*.

7. *Huetiana*, Boiss., frequently incorrectly offered as *Huetiana*, *Huetii*, and *Huetii* (*S. Cymbalaria*, Hort., not Linn.). Annual or biennial(?): sts. weakly erect or decumbent, flaccid, 4-6 in. high: lvs. soft, with age brown-striate below; lower lvs. reniform-cordate, base cordate or truncate, broader across, 5-7-lobed, lobes broad, obtuse or very shortly apiculate; upper 3-lobed or entire, ovate: infl. cymose with long erect pedicels; fls. small but numerous, bright yellow; calyx-lobes triangular, acute; petals oblong, obtuse, base distinctly clawed, 3 times the length of the calyx-lobes. May-Aug. Asia Minor.—Very closely allied to *S. Cymbalaria* and by some considered a variety of that species. It differs in its dwarfer less upright habit, fewer and more obtuse lobes of the lvs. and other technical floral characters and probably in its infl. being a cincinnus instead of a bostryx. A very effective plant for the rockwork.

Section III. MISCOPETALUM.

- A. *Rhizome rather thick: lvs. unevenly and coarsely crenate or dentate*..... 8. *rotundifolia*
 AA. *Rhizome slender: lvs. 5-9-crenate or shallowly-lobed, the lvs. smaller than the last*..... 9. *taygetea*

8. *rotundifolia*, Linn. Sts. 8-12 in. high, erect from a somewhat thickened rhizome, leafy and paniculate from the middle or above: lvs. rather thick, more or less hairy on both surfaces; basal and lower on petioles 3-4 times longer than the blades, reniform or orbicular, base cordate, unequally and coarsely crenate or dentate; cauline almost sessile, base obtuse or cuneate, with more or less incise-dentate lobes: infl. a branched panicle with long, slender glandular-hirsute peduncle and pedicels; fls. white, spotted with red or purple; calyx-tube very short, lobes triangular oblong, acute; petals oblong-lanceolate. May, June. Eu. and Asia. B.M. 424.—A very satisfactory species for moist and shady parts of the rockwork. Var. *glandulosa*, Griseb. (*S. glandulosa*, Hort. *S. lasiophylla*, Schott. *S. angulosa*, Schott. *S. rotundifolia* var. *angulosa*, Hort.). Sts. tall, glandular-pubescent: basal lvs. obtusely crenate; the cauline lvs. incise-dentate: the panicle branches spread out and many-fld.

9. *taygetea*, Boiss. & Heldr. (*S. rotundifolia* var. *taygetea*, Engl.). Sts. 3-6 in. high, erect from a slender rhizome, almost naked, pubescent: lvs. small, firm, sparse hirsute, slightly membranaceous-margined; the radical lvs. long-petioled, subcordate-reniform, broadly and obtusely 5-9-crenate; the cauline lvs. none or 1 or 2 minute ones which are 3-parted or linear: infl. loosely paniculate-corymbose; the branches 1-2-fld.: fls. white with purple dots; calyx-lobes oblong, rather obtuse; petals elliptical-lanceolate, obtuse. June-Aug. Greece.—Much of the material cult. under this name is really *S. cuneifolia*.

Section IV. TRIDACTYLITES.

10. *adscendens*, Linn. (*Muscaria adscendens*, Small). One to 6 in. high, the whole plant viscidulous and clothed with short glandular hairs: sts. erect: the basal lvs. crowded, the cauline few, cuneate, gradually attenuate all the way to the base, the apex rounded or truncate, 3-5-lobed, the lobes subequal, oblong or ovate, rather obtuse or acutish: infl. corymbose, sparingly branched from the middle or base of the fl.-st. branches erect; fls. white; calyx glandular-pilose, tube campanulate, in fr. rounded at the base and twice as long as the lobes; petals cuneate, emarginate, slightly 5-nerved, double as long as the calyx-lobes. June,

July. Eu. and in the Rocky Mts., S. Canada to Colo. and Utah.—A very common and widespread European species which has not been frequently cult.

Section V. NEPHROPHYLLUM.

- A. *Basal lvs. cuneate or spatulate*..... 11. *lactea*
 AA. *Basal lvs. cordate or reniform*.....
 B. *Infl. corymbose-paniculate*..... 12. *granulata*
 BB. *Infl. racemose, 1-6-fld.*..... 13. *rivularis*

3556. *Saxifraga Stracheyi*, as the flowers are appearing in earliest spring. (×¼)

11. *lactea*, Turcz. Cespitose, 4-6 in. high: sts. erect, glandular-pubescent below, paniculate above: lvs. light green, lower cuneate, 3-5-parted, lobes oblong, very obtuse, horizontal-spreading; upper 3-parted, lobes linear, obtuse: infl. axillary, with pedicels much longer than the fls., 2-fld., the terminal fl. exceeded by the lower; fls. white (milky white according to tradelists); calyx-lobes ovate, obtuse, longer than the tube; petals obovate-cuneate, lightly 3-nerved, 3 times as long as the calyx-lobes. June. Siberia.—Probably not in general cult.

12. *granulata*, Linn. MEADOW SAXIFRAGE. Sts. erect or ascending from a bulbiferous base, 6-20 in. tall, slightly foliose, often branched below, lax paniculate, soft-hirsute, glandular-viscous above: lvs. pilose, bearing bulblets in the axils, reniform, incise-lobed, lobes entire or crenate, decurrent at base on the hirsute petiole; cauline lvs. subsessile, wedge-shaped, 3-5-parted: infl. open, panicle, with glandulose elongated pedicels (sometimes contracted and umbel-like): fls. white, campanulate, somewhat drooping, about 1 in. diam.; calyx-lobes longer than the ovate tube, linear-oblong, obtuse; petals obovate-oblong, strongly attenuate at base, 3-nerved. April-June. Eu., N. Afr. Gn.W. 25:513.—The common meadow saxifrage of Eu. and an attractive plant. The species proper is, however, seldom cult. Var. *fiore-plena*, Hort. (*S. granulata* var. *plena*, Hort.), is the common form in cult. and differs only in its double fls. G. 25:201; 26:213. Gn.W. 23:389.

13. *rivularis*, Linn. Cespitose, the sts. ascending 1-3 in. high, more or less villous: basal lvs. with petioles 3-5 times longer than the blades, reniform, palmately 3-7-lobed, lobes obtuse, petioles with broad ciliate stipules; upper lvs. short-petioled, 3-lobed: infl. long, peduncles arising from the axils of the lower lvs., almost as long as the whole st.; fls. at the top short-pedicelled or sessile: fls. 1-5, white (often tinged purple), erect; calyx short-glandular pilose or rather glabrous, tube hemispherical, lobes ovate, obtuse, shorter than the tube; petals obovate-oblong, twice as long as the calyx-lobes. July, Aug. Circumboreal, in N. Amer. to the White Mts. and in the Rocky Mts. to Mont.

Section VI. DACTYLOIDES (MUSCARIA).

- A. *Lower lvs. undivided or short 3-5-pointed: petals mostly small (see also S. moschata and S. globulifera, which have some of the lvs. undivided)*.....
 B. *Plants loosely cespitose, with indeterminate secondary shoots borne in the lf.-axils*.....

- C. Infl. a few-fl. panicle borne on a fl.-st. 2-4 in. high. 14. *tenella*
- CC. Infl. 1-, rarely 2-fl., borne on a fl.-st. about 1 in. high. 15. *aphylla*
- BB. Plants densely cespitose: scape 1-fl. or few-fl., paniculate.
- C. Axils of the lvs. of the secondary shoots with buds of undeveloped cataphylla.
- D. Calyx-lobes mucronate. 26. *conifera*
- DD. Calyx-lobes obtuse. 28. *spatulata*
- CC. Axils of the lvs. of the secondary shoots without buds of undeveloped cataphylla.
- D. Lvs. linear. 16. *muscoides*
- DD. Lvs. spatulate. 17. *androsacea*
- AA. Lower lvs. more or less digitately lobed or divided (entire in Nos. 26 and 28): petals longer and broader than calyx-lobes.
- B. Secondary shoots indeterminate: the infl. borne in the axils of the lower lvs.
- C. The lvs. glandular-pilose, orbiculate-digitate: fls.-sts. 3-6 in. high. 18. *ajugifolia*
- CC. The lvs. not glandular, wedge-shaped: fl.-sts. 1½-3 in. high. 19. *perdurans*
- BB. Secondary shoots determinate, ending in an infl.
- C. Petals obovate-cuneate, attenuate-clawed.
- D. Blades of the almost sessile lvs. oblong-cuneate. 25. *pedemontana*
- DD. Blades of the petiolate lvs. ovate or orbicular.
- E. Divisions of the suborbicular or reniform lvs. lanceolate. 20. *geranioides*
- EE. Divisions of the ovate lvs. linear. 21. *pedatifida*
- CC. Petals obovate, obovate-oblong or oblong, not attenuate clawed.
- D. Plants loosely cespitose, frutescent, the rosettes of rigid lvs. of this year far removed from those of the previous year.
- E. Lvs. cuneately attenuate to the petiole; the lobes horizontally spreading.
- F. Lower lvs. incise 3-lobed; the midlobe usually entire. 22. *Camposii*
- FF. Lower lvs. pedately divided; the midlobe 3-parted. 34. *obscura*
- EE. Lvs. trifurcate, bowed-attenuate to the petiole; the lobes divaricate.
- F. Petiole deeply grooved; the midlobe of lf. entire. 23. *canaliculata*
- FF. Petiole not deeply grooved; the midlobe of lf. 3-toothed. 24. *trifurcata*
- DD. Plants densely cespitose, the rosettes of lvs. of this year close to those of the previous year (specimens of *S. decipiens* excepted).
- E. Axils of the lvs. of the secondary shoots without buds of undeveloped cataphylla.
- F. Petals oblong, equaling or rarely exceeding the calyx-lobes in width. 36. *moschata*
- FF. Petals obovate or obovate-oblong, exceeding the calyx-lobes in width.
- G. Nerves of the lvs. usually prominent.
- H. Blades of lvs. sessile or short - petioled; the midlobe oblong. 33. *exarata*
- HH. Blades of lvs. with petioles as long as the blades: the midlobe linear. 35. *mixta*
- GG. Nerves of the lvs. not at all prominent.

- H. Divisions of the lvs. more or less acute. 31. *decipiens*
- HH. Divisions of the lvs. more or less obtuse. 32. *cespitosa*
- EE. Axils of the lvs. of the secondary shoots with buds of undeveloped cataphylla.
- F. Calyx-lobes mucronate.
- G. Lvs. undivided and sessile. 26. *conifera*
- GG. Lvs. 3-lobed and petioled. 27. *hypnoides*
- FF. Calyx-lobes obtuse.
- G. The lvs. all undivided. 28. *spatulata*
- GG. The lvs. (the lowest excepted) lobed.
- H. Calyx-lobes ovate-triangular, about equaling the length of the tube. 29. *globulifera*
- HH. Calyx-lobes ligulate-lanceolate, twice the length of the tube. 30. *Maweana*

Subsection HOLOPHYLLÆ.

14. *tenella*, Wulf. Lax, cespitose, 2-4 in. high, with foliose, prostrate or erect caudicles: sts. erect, slender, glabrous: lvs. yellow- or apple-green, shining, thin but rather stiff, lower and also cauline, linear-subulate, cuspidate-aristate, margin setulose-ciliate or glabrous, glandulose-ciliate toward the base: infl. terminal, few-fl. panicles with slender pedicels longer than the fls.: fls. white or yellowish white; calyx-lobes triangular, acute, equaling the tube, glabrous; petals obovate-oblong, recurved above, 3-nerved, twice as long as the calyx-lobes. June, July. Mountains of Cent. Eu.

15. *aphylla*, Sternb. (*S. leptophylla*, Froel.). Loosely cespitose, about 1 in. high with numerous sparsely foliate caudicles with rosettes at the top: sts. sparsely glandular-pilose: lvs. light green, rather thin, entire or 3-5-cuspidate, the divisions ovate-lanceolate, obtuse: infl. almost leafless 1-fl., rarely 2-fl. glandular scapes: fls. light yellow; calyx-lobes ovate, acute; petals linear, acute, equaling the calyx-lobes. June, July. Mountains of Eu.

16. *muscoides*, All. Densely cespitose, 1-2 in. high, with short caudicles: sts. columnar, densely imbricate-foliose, ashy pilose: lvs. linear, rounded-obtuse, base attenuate, when dried 3-nerved, apex cinerous: infl. numerous, terminal, few-fl. racemes or more seldom several-fl. panicles with very short pedicels: fls. white or yellowish white (rarely citron-yellow or purple); calyx-lobes ovate, obtuse; petals round-obovate, very obtuse, smoothly emarginate, 3-nerved, twice as long as the calyx-lobes. July, Aug. High mountains from the Pyrenees to Austria. Gn. 76, p. 615.—Frequently confused with *S. moschata* and *S. cespitosa*. A strictly Alpine species forming a dense moss-like cushion, the uppermost lvs. of which are reddish toward the base and fresh green toward the apex and are rather fleshy. Suitable only for alpine-gardening. Var. *foliis-variegatis*, Hort., is a form with yellow-and-white variegated lvs. Very likely this really is a variety of *S. moschata*.

17. *androsacea*, Linn. Cespitose, 1-3 in. high (possibly more), with the basal and lower lvs. aggregated and sessile: lvs. dark green, shiny, spatulate or obovate, cuneate, apex entire or 3-5-toothed, the teeth short and acute, the central twice longer than the lateral, when dry 5-11-nerved, margin ciliate, at the top glandulose-ciliate; cauline lvs. oblong-lanceolate: infl. numerous, almost naked, sparsely glandular, 1-3-fl., rarely 5-fl. scapes: fls. small, clear white or greenish white; calyx-lobes ovate, obtuse, the base and margins glandular; petals obovate-oblong, 3-nerved, at the top emarginate, the uppermost portion reflexed, twice longer and broader than the calyx-lobes. June-Aug. Mountains of S. and Cent. Eu., also the Baikal region of Asia.

Subsection AXILLIFLORÆ.

18. *ajugifolia*, Linn., also spelled *ajugæfolia*. Cespitose, about 3-6 in. high: st. decumbent, rooting; lvs. sparsely glandular-pilose, light green, rather thick and fleshy, orbiculate-digitate, 3-5-parted, attenuate to the flat petiole, lobes lanceolate, acute: infl. 1-5 slender, nearly simple, few-fl. scapes arising from the axils of the lower lvs.; bracts linear, entire, acute; pedicels very short, puberulent: fls. rather small, whitish or clear milk-white; calyx-lobes ovate, acute; petals ovate-oblong, 3-nerved, very shortly clawed, twice longer than the calyx-lobes. May-July. S. Eu.

19. *perdûrans*, Kit. Cespitose, 1½-3 in. high: sts. procumbent: lvs. rather thick, bright green, the lower surface striped purple at the nerves, those of the young shoots and the lower cauline similar, without glands, wedge-shaped, attenuate to the flat petiole, palmately 3-5-parted, lobes horizontal spreading, oblong, obtuse, mucous, faintly 3-nerved: infl. a solitary, axillary, subsimple, few-fl. scape with a reddish base and one partially clasping lf.; bracts 3-parted or entire: fls. 1-5, cymose, white; calyx-lobes roundish; petals spreading, oblong, 3-nerved, more than twice as long as the calyx-lobes. June, July. Mountains of E. Cent. Eu.—Closely allied to *S. ajugifolia*.

Subsection CERATOPHYLLÆ.

20. *geranioides*, Linn. (*S. palmata*, Hort., not Smith and others). Biennial or perennial, cespitose, 2-10 in. high, with numerous frutescent subwoody, leafy caudicles: sts. erect, somewhat pilose: lvs. bright green, lower rather pilose, suborbicular or reniform, palmately 3-divided with the lateral lobes bifid, lobes lanceolate-acute or 2-3-toothed, base of the ciliate petiole dilate; cauline lvs. cuneate-ovate with narrow lobes: infl. subcorymbose, many-fl., with pedicels shorter than the fls.: fls. white, campanulate; calyx-lobes erect, linear-lanceolate, acute; petals obovate-oblong, long-clawed, more than twice longer than the calyx-lobes. May-July. Mountains of Eu.—Best prop. by seed. A showy little ground-cover; plant suitable for terraces and the like.

21. *pedatifida*, Ehrh. (*S. cuspidata*, Schleich.). Cespitose, 2-8 in. high, with frutescent, subwoody, leafy caudicles: sts. erect, rather stiff, puberulent: lvs. fresh green, the lower with ovate and pedate-parted blades, many-nerved and borne on flat petioles which are longer than the blades, the lateral lobes of which are 3-lobed, the lobules linear, entire and more or less mucronate; the lvs. of the young shoots longer-petioled and with longer, narrower lobes; the cauline lvs. 3-5-lobed; bracts narrowly linear: infl. subcorymbose, the peduncles much overtopping the lvs., the pedicels and calyx glandular-pilose: fls. 3-9 on a peduncle, campanulate, white; calyx-lobes erect, lanceolate, acute; petals obovate-oblong, 5-7-nerved, long-clawed, 2 or 3 times longer than the calyx-lobes. June. S. Eu.—Closely allied to *S. geranioides* but distinguished readily by the gradual narrowing of the blades, which are many-nerved into the petiole and also by the linear divisions of the lvs.

3557. *Saxifraga Camposii*.

22. *Campòsii*, Boiss. & Reut. (*S. Wallacei*, McNab. *S. Wallaceana*, Hort.). Fig. 3557. Perennial, loosely cespitose, 3-6 in. high, with slightly shrubby caudicles

covered with old retroflex lvs.: fl.-sts. erect, reddish, entirely glabrous: lvs. stiff, dark green, shiny, those of the young shoots and the lower ones incise-3-lobed, more than double the length of the strongly broadened, nerved petiole and having decidedly prominent nerves, the lateral lobes of the blade again 2-lobed or dentate with the teeth mucronulate, the midlobe usually entire, linear and mucronate; cauline lvs. cuneate, attenuate to the petiole, more obtusely dentate; bracts spatulate, acute: infl. terminal, 6-10-fl., more or less congested corymbs or panicles: fls. large, ¾ in. across, subcampanulate, white; calyx-lobes oblong, acute; petals rounded-obovate, shortly clawed, 3-nerved. May-July. Spain. B.M. 6640. Gn. 35, p. 392; 75, p. 335. A.F. 4:493. G.M. 43:192; 55:276; 57:620. J.H. III. 70:250.—This species has been intro. into Amer. but never succeeded well owing, it is said, to the hot climate. An attractive little plant on account of its showy fls. which are occasionally used for cut-fls.

23. *canaliculata*, Boiss. & Reut. Lax, cespitose, 6-8 in. high, with ascending caudicles which are covered below with old, rather remote lvs., and terminate in rosettes: fl.-sts. numerous, erect, very glabrous: lvs. very stiff, quite dark green, strongly viscid below, with transversely broader blade which is 3-parted and is borne on a flat, deeply grooved petiole, midlobe of the blade entire, the lateral ones 2-3-parted, with the lobes bowed and mucronate at their apex; cauline lvs. 3-parted; bracts linear, mucronate: infl. corymbose-paniculate: fls. white; calyx-lobes linear-lanceolate, mucronulate; petals obovate-oblong, attenuate to the claw, 3-nerved, twice as long as the calyx-lobes. July. Spain.—Allied to *S. Camposii* from which it differs in the more spreading divisions of the lvs. and the fact that the petioles are not broadened except at the base.

24. *trifurcata*, Schrad. Perennial, loosely cespitose, 4-8 in. high, with slightly shrubby leafy caudicles covered with old reflexed lvs.: fl.-sts. erect, glabrous: lvs. dark gray-green, viscid, twice as long as the petioles, palmately 3-parted, nerved, the lateral lobes of the blade sub-3-divided, the midlobe cuneate, 3-toothed, with the teeth mucronulate; cauline lvs. few, shorter-petioled, 3-parted; bracts linear, acute: infl. loosely paniculate; pedicels long: fls. milk-white, numerous; calyx glabrous, the lobes lanceolate, acute; petals obovate-oblong, 3-nerved, nearly 3 times the length of the calyx-lobes: fr. ovate. May. Spain. G.C. III. 48:295. F.E. 18:442.—A quick grower, which is frequently cult. abroad and which is also useful for pot cult. Var. *ceratophylla*, Hort. (*S. ceratophylla*, Dry.). Lvs. rigid and more deeply parted than the type and rather glaucous: fls. white, in lax panicles. June. Spain. B.M. 1651.

25. *pedemontana*, All. Sparsely glandular-pubescent, cespitose, 2-4 in. high, with densely leafy caudicles: lvs. bright green, those of the young shoots and the lower cauline, cuneate or obversely triangular, attenuate to the flat ciliate petiole which equals or is shorter than the 3-lobed blade, lobes horizontally spreading, the lateral ones bifid or all 3 incise-dentate, teeth obtuse or rather acute, obsoletely nerved; lower bracts cuneate, sessile, 5-7-parted or linear-oblong, obtuse: infl. few-lvd., rather glabrous scapes bearing corymbose panicles with slender pedicels which are glandular-pubescent as is the calyx: fls. large, campanulate, milk-white; calyx-lobes linear, obtuse; petals obovate-cuneate, attenuate to a claw, 3-nerved, double the length of the calyx-lobes. July. Mountains of S. Eu. Gn. 78, p. 271. Var. *cervicòrnis*, Engl. (*S. cervicòrnis*, Viv.). Younger lvs. longer-petioled, the blade 3-lobed; the lateral lobes bifid, less horizontally spreading, rather acute, the nerves decidedly prominent: the calyx-lobes rather acute. June. Sardinia and Corsica. Gn. 76, p. 19; 79, p. 29.

Subsection GEMMIFERÆ.

26. *conifera*, Coss. & Dur. Densely cespitose, $\frac{1}{2}$ –3 in. high, with numerous short, densely imbricate-folios caudicles: fl.-sts. stiff, ascending, few-lvd., purple below, densely glandular-pubescent above: lvs., those of the caudicles, subpatent; cauline erect-spreading; all of them undivided, sessile, oblong- or lanceolate-linear, cuspidate-aristate, leathery, margin short-ciliate: infl. 3–9-fld., corymbose-racemose or paniculate: fls. white; calyx pubescent-glandular, the lobes ovate-triangular, mucronate; petals not known. June, July. Spain.—Rare and seldom cult.

27. *hypnoides*, Linn. (*S. hibernica*, Hort.). Perennial, loosely cespitose, $1\frac{1}{2}$ –8 in. high, with herbaceous loosely foliose caudicles which are frequently reddish tinted: sts. erect, covered with very slender glands: lvs. light green, those of the caudicles rather thick, sparsely covered with slender hairs, when old rather glabrous, the suborbicular blade is cut all the way to the base, 3-lobed, and is borne on a rather broad, flat, 1-nerved, ciliate petiole which is shorter than the blade, lobes of the blade linear-lanceolate, a little dilated at the middle, acute or mucronate, with the lateral lobes divaricate, often 2-lobed; upper lvs. of the young shoots 3-toothed, attenuate to the long petiole, the uppermost linear-lanceolate; cauline lvs. few and like the bracts linear-lanceolate, ciliate and acute or mucronate: infl. 3–7-fld. panicles: fls. long-pedicelled, white, $\frac{1}{2}$ –1 in. diam.; calyx very densely glandulose, the lobes oblong-triangular, mucronulate; petals obovate, 3-nerved, twice longer than calyx-lobes: fr. ovate-globose. May–July. Mountains of Eu. as far north as Great Britain and Ireland. G.C. III. 43:302.—Frequently confused with *S. cespitosa*, Linn., and *S. decipiens*, Ehrh., and the varieties of the 3 species are almost hopelessly confused. Botanically speaking very probably Hooker in his Students' Flora of the British Islands, ed. 3, p. 142, is correct in referring *S. cespitosa* and *S. decipiens* as varieties to this species, but horticulturally at least they are better retained as separate species. Var. *gemmifera*, Hort. (*S. Kingii*, Hort., also spelled *Kingiana*), is a close-growing, compact form. Var. *purpurea*, Hort., is offered in the trade. Var. *rosea*, Hort., is offered in the trade. Var. *Whitlövii*, Hort. (*S. Whitlövii*, Hort.), is a form with closely packed foliage said to be suitable for edging. A variation of this is offered as *S. Whitlövii compacta*.

28. *spatulata*, Desf., also spelled *spatulata*. Perennial, very densely cespitose, $2\frac{1}{2}$ –4 in. high, with short, prostrate, very densely imbricate-folios caudicles: sts. slender, erect, few-lvd.: lower lvs. spatulate, ciliate, apex obtuse, rarely 3-toothed, 3-nerved; cauline linear: infl. 3–5-fld. corymbose panicles with pedicels longer than the fls. and sparsely glandular as is the calyx: fls. white; calyx-lobes ovate, very obtuse; petals obovate-oblong, twice as long as the calyx-lobes: fr. subglobose. June. N. Afr.—It is doubtful whether this species is hardy in E. U. S. It forms very thick, close mats which are reddish green or brownish with the silver-gray buds of the shoots dotted through. Not very showy, as the panicles are few-fld.

29. *globulifera*, Desf. Cespitose, about 3–4 in. high, with densely foliose, short caudicles: sts. prostrate, nearly glabrous or sparsely pilose, few-lvd.: lvs. bearing in their axils buds which are shorter than the lvs.; lvs. all nerved and borne on dilated rather flat petioles; the lowest spatulate-cuneate, entire; the others 3-lobed or, if the lateral lobes are bifid, 5-lobed, the midlobe oblong-lanceolate or, if all the lobes are tridentate, with the teeth rather acute; cauline lvs. oblong-linear, obtuse; bracts linear, obtuse: infl. 3–7-fld., subcorymbose-panicled; pedicels twice or more longer than the fls.: fls. white; calyx short-pilose, the lobes ovate-triangular, obtuse; petals obovate, 3-nerved, more than twice the

length of the calyx-lobes: fr. subglobose. May, June. S. Spain and N. Afr.

30. *Maweana*, Baker. Cespitose, about 6 in. high, with copiously branched, slender purple caudicles which are glandular-pubescent: fl.-sts. erect from a decumbent base: lvs. 6–8 to a shoot, loosely disposed, cordate-reniform, ternate-palmately-parted, the lobes with 3–5 oblong, subobtusate teeth; the petioles spreading, the upper half narrowly winged, often 2–3 times longer than the blade: axillary buds copious and robust: infl. laxly corymbose, 4–9-fld., borne on densely puberulent peduncles: fls. white, large; calyx-lobes ligulate-lanceolate, subobtusate, twice as long as the densely puberulent tube; petals obovate-cuneate. May. Morocco. G.C. 1871:1355.

Subsection CESPITOSÆ.

31. *decipiens*, Ehrh. (*S. cespitosa*, Hort., not Linn.). Cespitose, about 3 in. high, the caudicles herbaceous, rarely subligneous, rather long and leafy: sts. erect, few-lvd., smooth or at first glandular-pilose above: lvs. obovate-cuneate or spatulate, attenuate to the 1-nerved flat petiole, apex either 3-pointed or 3-lobed, lateral lobes 2- or 3-lobed or even the midlobe 3-lobed, the lobes oblong acute; cauline lvs. deeply 3-lobed: infl. loosely panicled, few-fld. (usually 3): fls. white; sepals oblong-lanceolate, subacute; petals obovate, 3-veined. May, June. Eu. L.B.C. 16:1510. Gn. 78, p. 271.—Approaches *S. cespitosa*, Linn., from which it is most easily distinguished by the acute lf.-lobes and subacute sepals; also approaches *S. hypnoides*, from which it is readily told as that species has buds in the axils of the lvs. of the barren shoots, whereas *S. decipiens* has not. Very variable; some of the cult. forms are: Var. *alba*, Hort., which has strong growth and white fls. Var. *Arkwrightii*, Hort. (*S. Arkwrightii*, Hort.). Rather tall-growing and free-flowering: the buds are suffused with a pale rose tint, but the fls. are pure white, flat, and large, $\frac{3}{4}$ –1 in. across. G.C. III. 45:314. Var. *bathoniensis*, Hort. (*S. bathoniensis*, Hort. *S. muscoides* var. *bathoniensis*, Hort.). A rapid grower, 10–14 in. high, with stout branching sts. bearing large scarlet-crimson fls. Var. *bristoleana*, Hort. Fls. bright crimson. Var. *Clibranii*, Hort. (*S. Clibranii*, Hort. *S. muscoides* var. *Clibranii*, Hort.). A plant of robust constitution, increasing rapidly and flowering freely; the foliage consisting of closely set rosettes of grass-green color: fl.-sts. 5–6 in. high, bearing fls. which are variously described as deep clear rose, rich crimson and rich blackish crimson, $\frac{1}{2}$ in. or more diam. G.C. III. 45:301. G. 36:395. Gn. 73, p. 264. J.H. III. 58:431. Var. *grandiflora*, Hort., is a free-growing plant 6–8 in. high with good-sized fls. of a rich red fading to pink. Very similar to var. *bathoniensis*. Var. *grœnlândica*, Engl. (*S. cespitosa* var. *grœnlândica*, Hort.). Densely cespitose, with few-lvd., few-fld. sts. and broadly cuneate, palmately 3–5-divided lvs.; the lobes ovate-lanceolate, acute. Ireland, Scotland, Wales, Norway, Iceland, Greenland, and Lab.

Var. *hybrida*, Hort., is probably a strain of red-fld. hybrids. It is suggested by one author that they are the result of a cross between *S. decipiens* and *S. granulata*. Some of the trade names of these variants are *S. decipiens hybrida grandiflora*, Hort. (*S. decipiens grandiflora hybrida*, Hort. *S. hybrida grandiflora*, Hort.), with large rich crimson or bright red fls. *S. hybrida grandiflora alba*, Hort., with neat cushions of dark green foliage and large pure white fls. resembling those of *S. Burseriana* var. *gloria*. *S. rosea superba*, Hort., which is said to be a remarkably effective variety with rich rose-red fls. G.M. 56:151. *S. hybrida splendens*, Hort., with rosettes of moss-like foliage covered with medium-sized brilliant red or dark carmine-red fls. All of these forms are much prized by fanciers abroad.

Var. *lutescens*, Hort., is offered in the trade. Var. *purpurea grandiflora*, Hort., is a trade name for a form which is said to be more vigorous than previous red saxifrages. It is said to form compact basal tufts with bright red fls., fading to rose, nearly 1 in. diam. April. Var. *sanguinea*, Hort. (*S. sanguinea superba*, Hort., not *S. sanguinea*, Franch. *S. muscoides* var. *sanguinea superba*, Hort.). Habit neat and compact, growth rapid: fls. rich blood-red, well retained when old. Var. *Sternbergii*, Engl. (*S. Sternbergii*, Willd. *S. hibernica*, Haw., not Sternb. *S. hypnoides* var. *Sternbergii*, Hort.). Lvs. ciliate, somewhat pedate; the midlobe entire, the lateral 2-parted, or the midlobe and also the lateral 3-parted; the divisions rather obtuse. Germany, Ireland, Norway, and Greenland. Var. *villösa*, Engl., is a form which is villous and canescent and has white fls.

32. *caespitosa*, Linn., more commonly spelled *caespitosa* (*Muscaria caespitosa*, Haw.). Cespitose, 2-6 in. high, a robust grower with short, more or less densely foliose caudicles: sts. few, few-lvd., densely glandular above: lvs. of the caudicles deep green, smooth, nearly glabrous, either cuneate, attenuate to the petiole, the apex 3-toothed, or obovate-cuneate, attenuate to a petiole double the length of the blade, 3-parted (rarely 5), the lobes linear and obtuse; infl. terminal, 1-5-fld.; fl.-sts. stoutish: fls. white; sepals oblong-deltoid, obtuse; petals narrowly obovate or oblong-obovate, rounded at the apex. June-Aug. N. Eu., N. Asia, and N. Amer., Greenland, and Lab., the Rocky Mts. of N. U. S. and Canada to the Pacific coast, south there to Wash. and Ore. Gn. 76, p. 283.—Probably the true *S. caespitosa* is rare in cult. Var. *hirta*, Hort. (*S. hypnoides* var. *hirta*, Hort.). A distinct form with very hairy lvs. giving it quite a white, woolly appearance. Var. *incurvifolia*, Groves (*S. incurvifolia*, D. Don), has the cauline lvs. more numerous with incurved lobes. Mountains of Scotland, Wales, and Ireland.

Subsection EXARATÆ.

33. *exarata*, Vill. Fig. 3558. Cespitose, 3-6 in. high, with subligulate and also herbaceous caudicles which are rosulate at their tips: fl.-sts. erect, few-lvd., soft hirsute below, mixed with slender glandular hairs above: lvs. of the caudicles cuneate, sessile or petiolate, 3-lobed, the midlobe oblong-obtuse, the lateral either undivided or 2-parted, rather acute; lvs. of the young shoots 3-divided or lanceolate undivided; cauline lvs. 3-parted; bracts lanceolate; infl. paniculate, 4-10-fld.; the pedicels and calyx short-glandular: fls. usually white or yellowish white but sometimes rose or purple; calyx-lobes obtuse or subacute; petals obovate or obovate-oblong, 3-nerved, double the length of the calyx-lobes. June, July. Alpine regions of Eu., Pyrenees to Greece. G.M. 54:555.—A variable species not commonly cult.

34. *obscura*, Gren. & Godr. Cespitose, 3-8 in. high, with somewhat shrubby, elongated caudicles covered with old lvs.: fl.-sts. erect, slender, nearly naked, pilose: lvs., those of the shoots and the lower, pedate-divided, with lanceolate lobes, linear, long-petioled, broadened at base, lateral lobes bifid or 2-toothed, teeth lanceolate, the midlobe 3-parted; cauline lvs. 3-5-parted: infl. 5-15-fld., with pedicels shorter than

the fls.: fls. white; calyx-lobes linear, subacute; petals oblong, not at all clawed, double the length of the calyx-lobes. July, Aug. Pyrenees.—A rare, little-known species.

35. *mixta*, Lapeyr. The whole plant glandular-pilose, densely cespitose, 2-3 in. high, with subwoody columnar caudicles which are densely imbricate with persistent old lvs.: fl.-sts. erect: lvs. mostly light green, soft and more or less strongly nerved, those of the caudicles and shoots cuneate, borne on a large petiole which equals the blade in length, 3-lobed, the lobes horizontally spreading, obtuse or at other times the lobes 3-lobed, the lobules linear, obtuse; cauline lvs. obovate-cuneate, 3-lobed; bracts oblong, obtuse; infl. corymbose-paniculate: fls. milk-white, not uncommonly purple-nerved; calyx-lobes ovate, obtuse; petals round-ovate, 3 times as long as the calyx-lobes. June-Aug. Pyrenees.—Said to be an attractive little plant with a good habit, but the species proper appears not to have been cult. Var. *Irtiiana*, Engl. (*S. Irtiiana*, F. Schultz). About 2 in. high, differing from the type in the deep green, broadly

3558. A group of saxifragas in a rock-garden. Left, *S. Sibthorpii* (see supplementary list, page 3105); center, *S. altissima* (No. 72); right, *S. exarata* (No. 33).

obovate-cuneate lvs. which are 5-9-divided, the lobes being linear, short, and obtuse; in the few-fld., narrow panicle and also in having the white fls. veined with purple. May-July. Pyrenees.—The variety is more common in cult.

Subsection MOSCHATÆ.

36. *moschata*, Wulf. (*S. muscoides*, Hort., not All. *S. muscoides* var. *moschata*, Hort.). Cespitose, 1-5 in. high, the caudicles herbaceous or subligulate, foliose: lvs. smooth; nerves not prominent, glabrous or glandular-pilose; those of the caudicles linear, entire, obtuse or cuneate, 3-, rarely 5-parted, lobes linear, obtuse, horizontally spreading; cauline lvs. few, 3-lobed or entire; bracts linear, obtuse; infl. racemose or paniculate, 1-10-fld., borne on erect, few-lvd., subglabrous or glandular-pilose fl.-sts.: fls. commonly yellowish but not uncommonly rose or dark purple, seldom almost white; calyx-lobes ovate, obtuse; petals spreading, oblong, obtuse, 3-nerved, slightly exceeding the calyx-lobes: fr. ovate-globose. May, June. Cent. and S. Eu. Gn. 76, p. 283 (as *S. caespitosa*).—Linnæus included this under *S. caespitosa* and in consequence the two species have been commonly confused. There seems no doubt, however, that Linnæus intended his *caespitosa* to apply to the Lapland form. *S. moschata* is readily separated from the true *S. muscoides* by the lobed lvs.; those of the latter are unlobed and linear. A very variable species; some of the varieties in cult. are: Var. *Alliönii*, Engl. (*S. Alliönii*, Gaud., not Baumg. *S. muscoides* var.

Alliönni, Hort.). Laxly caespitose, robust, 3-6 in. high: lvs. long-petioled, 3-5-lobed at the apex; the lobes short and very obtuse: infl. many-fld., paniculate: fls. white; petals broader and obovate. Switzerland. Var. *atropurpurea*, Sternb. (*S. atropurpurea*, Sternb., *S. muscoides* var. *atropurpurea*, Ser. *S. muscoides* var. *purpurea*, Sternb.), has the petals dark purple and sometimes obovate-oblong. G.W. 5, p. 254. G.M. 58:1. Var. *compacta*, Correv. (*S. muscoides* var. *compacta*, Koch). Tufts small and very dense: lvs. densely imbricate: sts. usually 1-fld., often scarcely $\frac{1}{2}$ in. high. Var. *densa*, Hubb. (*S. muscoides* var. *densa*, Hort. *S. densa*, Hort., not Willd.), has the foliage so tightly packed as to give the effect of turf: fls. white. Var. *Fergusonii*, Hubb. (*S. Fergusonii*, Hort.). Free-flowering, so much so as nearly to hide the vivid green carpet of foliage: fls. bright crimson, in clusters on very short sts. "Guildford Seedling," also treated as a form of *S. muscoides* and *S. Rhei*, appears to be nothing more than a later-flowering form of var. *Fergusonii*. Gn.W. 23:427. Var. *pygmæa*, Engl. (*S. pygmæa*, Haw. *S. muscoides* var. *pygmæa*, Hort.). Densely caespitose: the lvs. rather thick, all entire, the apex rotund-obtuse or with three crenatures. Var. *Rhei*, Hort., also spelled *Rhai* and *Rhai* (*S. Rhei*, Schott. *S. caespitosa* var. *Rhei*, Hort. *S. muscoides* var. *Rhei*, Hort.). Forms mossy hillocks covered in April and May with masses of rather large rose-colored fls. Grows about 6 in. high. A form of this more commonly cult., is known as *S. Rhei superba* or *S. muscoides Rhei superba*, and has a more robust habit and larger deeper colored fls.

Section VII. BORAPHILA (SPATHULARIA, MICRANTHES).

- A. Petals lanceolate, clawed, usually somewhat unlike.
 - B. Infl. without bulblets: fls. numerous. 37. *leucanthemifolia*
 - BB. Infl. with bulblets: fl. solitary at the end of the main st. 38. *bryophora*
- AA. Petals obovate or obovate-rotundate, about alike.
 - B. Lvs. more or less spatulate, ovate, or obovate.
 - C. The lvs. thin and herbaceous.
 - D. Lf.-blades about as broad as long.
 - E. Infl. many-fld., corymbose-paniculate: sepals not reflexed. 39. *davurica*
 - EE. Infl. few-fld., loosely paniculate: sepals reflexed. 40. *lyallii*
 - DD. Lf.-blades elongated. 41. *micranthidifolia*
 - CC. The lvs. thick, leathery.
 - D. Blades of lvs. elongated or elongate-cuneate.
 - E. Margins of the oblanceolate or oblong-spatulate lvs. remotely short-dentate: petals oblong-linear or linear-lanceolate. 42. *pennsylvanica*
 - EE. Margins of the ovate-oblong lvs. entire or slightly sinuate-crenate: petals obovate. 43. *integrifolia*
 - DD. Blades of lvs. ovate or obovate.
 - E. Cymules compact or closely corymb-like at maturity: lvs. roundish ovate. 44. *nivalis*
 - EE. Cymules open and often raceme-like at maturity: lvs. ovate, obovate or spatulate. 45. *virginiensis*
- BB. Lvs. reniform or suborbicular.
 - C. Bulblets lacking in the axils of the basal lvs. 46. *punctata*
 - CC. Bulblets present in the axils of the basal lvs. 47. *Mertensiana*

37. *leucanthemifolia*, Michx. (*S. Michauxii*, Brit. *Spatularia petiolaris*, Small). Five to 15 or more in. high, caudices short: lvs. short-pilose on both sides, the basal fleshy, bright green, long-spatulate, cuneate-attenuate to the margined petiole, coarsely dentate, the teeth equal and acute; lower bracts linear-lanceolate,

narrowly dentate, upper ones nearly entire: infl. 1 or more scapes arising from the axils of the basal lvs. and branching paniculate from the middle, with the branches more or less diffuse; pedicels slender: fls. white, numerous and star-like; sepals lanceolate; petals unequal, the 3 larger ones with 2 light yellow spots at their cordate base, twice as long as the sepals: fr. ovate. June. Mountains of Va. to N. C. and Ga. L.B.C. 16:1568. B.M. 2959. B.B. 2:176; (ed. 2) 2:221 (as *Hydatia petiolaris*).

38. *bryophora*, Gray (*Spatularia bryophora*, Small). Two to 8 in. high, slender: lvs. 1 in. or less long, basal rather far apart, rosulate at the top of the slender caudices, oblong-elliptic to oblanceolate, obtuse, entire, ciliate: infl. solitary or tufted naked scapes, paniculately branched, the branches erect-spreading, 1-fld. at the end of the main st.; pedicels drooping: fls. white; sepals oblong to ovate; petals unequal, the 3 upper ovate with 2 spots at their cordate base, the 2 lower ovate, with abruptly narrowed base. Sierra Nevada Mts., Calif.—At one time offered by dealers in native plants.

39. *davurica*, Pall., also spelled *dahurica* (*Micranthes davurica*, Small). Three to 8 in. high: rhizome thick: lvs. basal, rather stiff, forming a rosette, sparsely covered with very short hairs, obovate-cuneate, rounded at the apex, deeply and evenly dentate, teeth ovate, acute, blades cuneate-attenuate at the base to the petiole which is membranaceous sheathing at its base; bracts oblong-lanceolate, the lowest of them oblong-cuneate: infl. erect naked scapes, which are solitary or several together, and are covered with very slender canescent, partly glandular hairs, many-fld. and corymbose-paniculate branched from the middle; pedicels filiform: fls. white, numerous; sepals yellow-green, ovate, rather acute, erect-spreading and not reflexed in age; petals obovate-oblong, scarcely twice as long as the sepals. E. Siberia and the islands of Bering Sea.—Much of the so-called American *S. davurica* and apparently more or less of the material cult. as *S. dahurica* is really *S. lyallii* from which it differs in having the peduncles hairy instead of glabrous and many- instead of few-fld., smaller fls. and other characters. Somewhat similar to *S. virginiensis*.

40. *lyallii*, Engl. (*S. dahurica*, Lyall. *Micranthes lyallii*, Small). Four to 15 in. high: rhizome slender: lvs. fresh green, obovate ("flabellate, varying to suborbicular or reniform-flabellate"), cuneate, attenuate to a basally dilated petiole, equally serrate-dentate above, glabrous, almost nerveless: infl. 6-10-fld. loosely paniculate scapes which are naked, slender, erect, almost glabrous, with very slender, erect-spreading later erect pedicels which are purple almost glabrous: fls. milk-white; calyx purple, the sepals ovate-triangular, reflexed; petals obovate-rotund, slightly clawed, 1-nerved. Rocky Mt. region, Brit. Col., Alaska, and Bering Sea region.—Has been confused with *S. davurica*, Pall., which see.

41. *micranthidifolia*, Steud. (*S. erösa*, Pursh. *Micranthes micranthidifolia*, Small). Up to 3 ft. high: lvs. all basal, oblong or oblanceolate, obtuse, attenuate to a flat petiole which is partly clasping at the base, erose-dentate, sparsely and also very shortly pilose, margin short-ciliate: infl. paniculate, loosely fld. and elongated, borne on a tall softly pilose scape; pedicels filiform, densely covered with slender glandular hairs, viscid: fls. numerous, white; sepals linear-lanceolate, obtuse, finally reflexed; petals oval, obtuse, with a yellow blotch below the middle, slightly longer than the sepals. June, July. Cold mountain brooks and wet rocks, Pa. to N. C. and Tenn. B.B. 2:174; (ed. 2) 2:219.—Occasionally cult.

42. *pennsylvanica*, Linn. (*Micranthes pennsylvanica*, Haw.). SWAMP SAXIFRAGE. Tall and stout, up to 3 ft or more high, viscid pubescent: rhizome thick: lvs. all

basal, sometimes almost 1 ft. long, oblanceolate or oblong-spatulate, attenuate to a short petiole which is half clasping at the base, obtuse, very shortly and also remotely dentate, margin short-ciliate: infl. 4-8-fld. cymes in a large panicle at first clustered, borne on a naked erect scape which is few-striate, shortly pilose, toward the top glandulose-pilose: fls. numerous, small, greenish; calyx-lobes deltoid, spreading, in fr. reflex; petals oblong-linear or linear-lanceolate, 1-nerved, a little longer and narrower than the calyx-lobes. June, July. Swamps and low meadows, Maine to Ont. and Minn., south to Va. and Mo. B.B. 2:173; (ed. 2) 2:219.—Recommended as a bog-plant.

43. *integrifolia*, Hook. (*Micranthes integrifolia*, Small). Whole plant glandular-pilose, viscid, very viscid above, 4-14 in. high: caudex short and somewhat woody, the st. always solitary: basal lvs. dark green, submembranaceous, ovate-oblong, very obtuse, entire or very slightly sinuate-crenate, base spatulate: infl. paniculate, more or less loosely so or spike-like, borne on an erect naked scape: fls. white, small; calyx rather glabrous, the lobes ovate, obtuse, spreading, at length reflex; petals obovate, slightly emarginate, 1-nerved, a little longer than the calyx-lobes. Calif. northward and in the Rocky Mts.—Occasionally offered by dealers in native plants.

44. *nivalis*, Linn. Two to 6 in. high: rhizome rather terete, short and simple but thick and hard, crowned with a tuft of lvs.: lvs. rather thick and leathery, roundish-ovate, generally abruptly narrowed to the petioles, obtuse, sharply crenate-serrate, upper surface dark green, under surface purple or red and often pubescent; bracts broad, purple or red: infl. composed of cymules aggregated into one or more terminal conspicuously bracted heads and borne on erect solitary or clustered purple or purple-tinged scapes which are glandular-viscid especially above: fls. white, very short-pedicelled or sessile; sepals ovate or deltoid-ovate, obtuse, ciliate; petals oblong to elliptic, mostly obtuse, narrowed into claw-like bases or scarcely so. June, July. Circumboreal, including N. Great Britain. B.B. 2:174; (ed. 2) 2:218 (as *Micranthes nivalis*).

45. *virginienensis*, Michx. (*Micranthes virginienensis*, Small). Low, viscid-pubescent plant, 3-12 in. high (occasionally taller): lvs. rosulate, thickish, ovate, obovate or spatulate, narrowed into a broad petiole, both surfaces glabrous or the upper short-pilose and the lower hirsute, crenate-toothed: infl. solitary, a small cyme, close at first, becoming loose and paniculate, which is borne on a hirsute and glandular-soft-pilose scape: fls. white, small, few or many; sepals ovate, mostly obtuse; petals obovate-oblong, double the length of the sepals: fr. ovate, the follicles united merely at base, purplish. April-June. Common on rocks and dry hillsides. New Bruns. to Minn., south to Ga., Mo., and Tenn. B.M. 1664. L.B.C. 17:1699. B.B. 2:174; (ed. 2) 2:218.—A very attractive spring-blooming plant for partially shaded spots in the wild-garden or rockery. Var. *fiore-pleno*, Hort., is a double-fld. form.

46. *punctata*, Linn. (*S. arguta*, Don. *S. æstivalis*, Fisch. & Mey. *Micranthes arguta*, Small. *M. æstivalis*, Small). Six to 18 in. high: rhizome rather stout and woody: lvs. forming a basal rosette, dark green, reniform to suborbicular, equally and strongly dentate or crenate, with long almost filiform, channeled petioles: infl. a terminal, many-fld., crowded or loose panicle which is borne on the solitary, erect or ascending naked scape: fls. white, not punctate; sepals ovate-oblong, rather acute and reflexed; petals obovate or oblong, twice as long as the sepals. Asia, W. N. Amer., and in the Rocky Mts.—A variable species, the American representatives of which have been separated as *S. arguta* and *S. æstivalis*, but the differences seem too slight to be considered specific.

47. *Mertensiana*, Bongard (*Heterisia Mertensiana*, Small). Perennial, 4-13 in. high, subpubescent: lvs. basal, in a rosette, subrotund, base cordate, incise-lobed, the lobes quadrate, 3-toothed with the teeth obtuse or acute; the petioles long, slender, pilose and at the base with a long membranaceous sheath: infl. a loosely diffuse panicle with erect-spreading glandular-pubescent branches borne on a slender erect almost naked green scape: fls. white with very long pedicels; sepals ovate, obtuse, reflexed; petals oblong, obtuse, double the length of the sepals. Alaska to Alberta, south to Mont. and Calif.—Very similar to *S. punctata* but readily distinguished by the incise-lobed lvs.

Section VIII. DIPTERA.

- A. Lvs. roundish, more or less deeply 7-lobed, serrate: stolons when present short.
 B. Longer petals entire. 48. *cortusifolia*
 BB. Longer petals strongly serrate. 49. *Fortunei*
 AA. Lvs. roundish or ovate, remotely dentate: stolons usually long and slender.
 B. Margins of lvs. doubly crenate-dentate; the petiole twice as long as the blade: plant usually tall. 50. *sarmentosa*
 BB. Margin of lvs. coarsely dentate or undulate dentate; the petiole as long as or slightly longer than the blade: plant low, not over 6 in. high. 51. *cuscutæ* [formis]

48. *cortusifolia*, Sieb. & Zucc., also spelled *cortusifolia*. From 6-12 in. high, not stoloniferous: lvs. basal, rather thick and fleshy, bright green, the lower part reddish, strigose-pilose, margin ciliate, roundish, 7-lobed, midlobes larger and simple or 3-lobed, acute-serrate, base cordate; petioles 3-4 times as long as the blade and broadened into a sheath ciliate with long rusty brown hairs: infl. laxly paniculate, terminal on an erect, striate, strigose-pilose scape; pedicels long, very slender, erect: fls. white; calyx-lobes lanceolate, acute; petals 3-nerved, unequal, 3 (generally) slightly longer than the calyx-lobes and obovate-lanceolate, the other 2 (sometimes 1-3) 8-10 times longer and quite entire, very long-attenuate to a claw. Oct. Japan. B.M. 6680. Var. *máddida*, Maxim. (*S. máddida*, Makino). Lvs. thin-membranaceous, deeply lobed, with the lobes 3-lobulate and incise-dentate. Oct. Japan. G.C. III. 46:370.

49. *Fórtunei*, Hook. (*Bergenia Fórtunei*, Stein). Perennial, scarcely (if at all) sarmentose, up to 2 ft.: lvs. dark green, one-colored, basal, thick, strigose-pilose, rounded-reniform, nerved, somewhat 7-lobed, the lobes rounded, strongly and acutely lacinate-serrate; petioles longer than the blade, thick, sheathing, with the sheaths ciliate-dentate: infl. loosely paniculate, borne on a stout, erect, strigose-pilose scape; the panicle-branches glandular, spreading, 4-7-fld.; pedicels nodding: fls. white; calyx-lobes ovate, rather obtuse, spreading; petals 1-nerved, unequal, 4 smaller, lanceolate, very entire or subentire, the fifth much longer, 3 or 4 times larger than the others, strongly serrate. June-Oct. Japan. B.M. 5377. G.L. 24:351. Gn. 74, p. 622; 78, p. 564. G.C. III. 45:20. G. 6:445. G.W. 14, p. 398. Gn.W. 24:759.—A very showy species which is not entirely hardy in England, requiring winter protection. Var. *tricolor*, Hort., is a form with the lvs. irregularly blotched with rose, white, and yellow. F.S. 21:2227, 2228.

50. *sarmentosa*, Linn. (*S. japonica*, Hort. *S. chinensis*, Lour.). STRAWBERRY GERANIUM. In England known as MOTHER OF THOUSANDS, a name also applied to *Linaria Cymbalaria*. OLD MAN'S BEARD. Fig. 3559. Perennial, 9-24 in. high, stoloniferous, the stolons long and filiform: caudex short: lvs. basal, rather thick, strigose-pilose, reniform-rotundate, rarely rounded-ovate, nerved, doubly crenate-dentate with broad acute teeth, upper surface green veined white, lower surface

reddish; petioles twice as long as the blade, semi-terete: infl. loosely paniculate, borne on an erect, strigose-pilose scape, the panicle-branches glandulose, spreading, 4-7-fld.: fls. white, numerous; calyx short-glandular, the lobes ovate, obtusish or acute, spreading; petals 1-nerved, clawed, unequal, the 3 smaller ovate, acute, of these the two outer have a yellow spot, the middle one 2 scarlet spots, the other two 3-4 times larger and lanceolate-elliptic. May-Aug. Japan, China. B.M. 92. G.C. III. 7:237 (showing irritability of plant to light). Gn. 30, p. 363; 32, p. 37. R.H. 1876, p. 427. G. 25:365. Gn. W. 25:781.—An old-time greenhouse plant, and also one of the commonest window-garden subjects. Of easiest cult. Not quite hardy in England but frequently used in sheltered rock crevices and slightly protected. Var. *tricolor*, Sieb. (*S. tricolor*, Hort. *S. tricolor superba*, Hort.), has lvs. handsomely marked with creamy white and red variegations. G.Z. 9:32. Less hardy than the type.

51. *cuscutæformis*, Lodd. Perennial, 3-6 in. high, stoloniferous, the stolons filiform, often branched and tangled in one another like the sts. of *cuscuta*: lvs. basal, rather thick, plano-convex, both surfaces strigose-pilose, green, white-veined, suborbicular or ovate, nerved, coarsely toothed or undulate-dentate, teeth broad-acuminate, becoming obtusish with age; petioles longer than or equaling the blade, rather terete and thick: infl. laxly secund-paniculate from below the middle of the slender, ascending, strigose-pilose scape; the panicle-branches glandulose, erect-spreading, slender, 2-3-fld.: fls. white; calyx very short-glandular, the lobes ovate, acutish, spreading; petals 1-nerved, very short-clawed, lanceolate-elliptic, 3 of them smaller and often pink toward their base and with a yellow spot, the other 2 slightly or twice longer. June, July. Japan. L.B.C. 2:186. B.M. 2631.—Not hardy in England unless very heavily protected.

Section IX. HIRCULUS.

- A. *Petals obovate*. 52. *diversifolia*
 AA. *Petals elongated, oblong or ovate-oblong*.
 B. *Infl. 3-12-fld., corymbose-panicled:*
the lower lvs. lanceolate. 53. *turfosa*
 BB. *Infl. 1-3- (rarely 5-) fld., racemose:*
the lower lvs. spatulate. 54. *Hirculus*

52. *diversifolia*, Wall. Eight to 18 in. high, forming tufts of basal lvs.: sts. hirsute below and glandular (becoming glabrous with age) above, erect and foliose: lvs. polymorphous, the lower petioled, ovate, obtuse or cordate-based, subacute, undulate, sparsely hirsute or glabrous; cauline mostly sessile, very entire, oblong-lanceolate, obtuse and glandular: infl. corymbose-racemose or paniculate, rarely few-fld.: fls. yellow, obscurely spotted, $\frac{1}{2}$ - $\frac{3}{4}$ in. across; sepals ovate, spreading, at length reflexed; petals obovate, short-clawed, 5-nerved with 4 glands at their base, exceeding the sepals. July-Sept. Himalayas and China. B.M. 6603.—Said to be the handsomest of the group and very showy when massed. Var. *foliata*, Hubb. (forma *foliata*, Engl. & Irmscher). Sts. erect, with 1 or more lvs., 3-20-fld.: lvs. cordate-ovate, glabrous or very shortly and densely glandular-pilose on the margin: fls.

golden yellow; sepals with the nerves mostly parallel. Aug., Sept. China.

53. *turfosa*, Engl. & Irmscher. Sts. erect, 7-14 in. high, rather densely foliose, reddish and glabrous below, pale and short-glandular-pilose above, stoloniferous at base, the stolons about 4 in. long and laxly foliate: basal and also the lower st.-lvs. lanceolate, obtuse, narrowed to a petiole as long as the blade, glabrous; middle and upper cauline lvs. sessile, oblong-lanceolate, coriaceous, glabrous; the uppermost narrower, their margin and often the upper surface densely glandular-pilose: infl. 3-12-fld., corymbose-panicled; pedicels bracteolate at base, densely short-glandular-pilose: fls. golden or orange-yellow; sepals oblong-ovate, glandulose, reflexed; petals oval or oblong-ovate, short-clawed, 3-nerved, lateral nerves often bifid. Sept., Oct. China.

54. *Hirculus*, Linn. (*Leptasea Hirculus*, Small). Perennial, 4-12 in. high: basal shoots or surculi short, prostrate, filiform, fuscous-villous and remotely foliose: sts. erect, leafy: lvs. lanceolate, flat, entire and obtuse; the lower and those of the surculi spatulate, attenuate to the ciliate petiole, the middle and upper lvs. sessile: infl. terminal, 1-3- and rarely 5-fld.; the peduncles erect, 1-fld., brown-villous and glutinose: fls. yellow, $\frac{1}{2}$ - $\frac{3}{4}$ in. across; sepals oblong, very obtuse, reddish ciliate; petals ob-

long or ovate-oblong, spotted with red at the base, 3 times longer than the sepals: fr. ovate. July-Sept. N. temperate, subarctic and alpine regions. B.B. 2:171; (ed. 2) 2:216.—An excellent plant for cold damp locations as it is a native bog-grower. Var. *grandiflora*, Hort., is freer flowering than

the type and has golden yellow fls. 1 in. across; more desirable than the type.

Section X. TRACHYPHYLLUM (LEPTASEA, CHONDROSEA).

- A. *Stolons or runners absent: the young shoots leafy and also floriferous*.
 B. *Sts. with a basal rosette of lvs., but few-lvd. above*. 55. *chrysantha*
 BB. *Sts. equally and loosely lvd.*
 C. *Axils of the cauline lvs. with buds*.
 D. *Peduncles glabrous: calyx-lobes ovate-triangular*. 56. *aspera*
 DD. *Peduncles glandular: calyx-lobes lanceolate*.
 E. *Lvs. linear-lanceolate, gray-green; margin ciliate or spinulose*. 57. *bronchialis*
 EE. *Lvs. lanceolate; under surface lineolate; margin strigose, with white hairs*. 58. *gemmipara*
 CC. *Axils of cauline lvs. without buds, the lowest, however, have more or less elongated leafy shoots*.
 D. *Petals oblong, 1-nerved: the cauline lvs. oblong*. 59. *aizoides*
 DD. *Petals obovate, 3-nerved: the cauline lvs. lanceolate*. 60. *cinerascens*
 AA. *Stolons or runners present: the young shoots sarmentose*.
 B. *Fls. long-pedicelled*. 61. *Brunoniana*
 BB. *Fls. almost sessile*. 62. *flagellaris*

55. *chrysantha*, Gray (*Leptasea chrysantha*, Small). Dwarf caespitose plant, 1-2 in. high, with creeping

3559. *Saxifraga sarmentosa* ($\times \frac{1}{2}$). No. 50.

shoots: lvs. mostly basal, in a rosette (a few cauline), imbricate, oblong-ovate, glabrous and fleshy: infl. 1-3-fld., terminal on filiform, glandular-pubescent peduncles: fls. large, yellow; calyx-lobes ovate or oblong-ovate, obtuse; petals oval to broadly obovate, much longer than the calyx-lobes. Mountains of Colo. and New Mex.—Has been offered by dealers in native plants.

56. *áspera*, DC. More or less caespitose, 4-6 in. high, with prostrate, mostly dark purple caudicles: fl.-sts. erect or ascending, remotely lvd.: lvs. pale green, shiny, lanceolate-linear, spiny-aristate and ciliate, those of the caudicles bearing buds in the axils: infl. 1-fld. or few-fld. panicles, on glabrous peduncles: fls. yellowish white; calyx sparsely glandular below, the lobes ovate-triangular mucronulate; petals oblong or obovate-oblong, 3-nerved, double the lengths of the calyx-lobes, oblique truncate. May, June. Mountains of Eu.—A rock-loving species suitable for rockeries and alpine gardens, best grown in a moist but well-drained spot. Little known in Amer. Var. *bryoides*, DC. (*S. bryoides*, Linn.). Lvs. of the caudicles very dense, slender ciliate, the apex incurved; the cauline lvs. subapproximate, erect, appressed to the sts. which are 2-3 in. high and 1-2-fld.

57. *bronchialis*, Linn. Dwarf, caespitose, 4-8 in. high: sts. ascending, densely foliose at the base; fl.-sts. few-lvd.: lvs. stiffish, almost leathery, gray-green, shiny, linear-lanceolate, margin ciliate or spinulose: infl. few or many-fld., paniculate, borne on erect-spreading glandulose pedicels: fls. yellowish white with orange-red dots; calyx-lobes oblong-lanceolate, rather obtuse, glabrous; petals oblong, 3-nerved, twice as long as the calyx-lobes. May. Asia and Alaska.—The material from the Cascade Mts. of Wash. to Alberta and southward along the Rocky Mts. to New Mex., which has passed as *S. bronchialis*, has been separated under the name of *S. austromontana*, Wiegand (*S. bronchialis*, Pursh, not Linn. *Leptásea austromontana*, Small). It differs from *S. bronchialis* in its more subulate, darker green lvs., more slender often purple sts., more slender pedicels, smaller white petals with purple dots above and not clawed at the base. *S. austromontana* is probably not in cult.

Var. *cherlerioides*, Engl. (*S. cherlerioides*, Don. *S. Stelleriana*, Merck., also spelled *Stellariana*. *Leptásea cherlerioides*, Small). Densely caespitose, with the caudicles very densely imbricate-leafy: lvs. short, flat above, convex below, somewhat spatulate, acute-mucronate: fl.-sts. shorter, 2-3 in. high, few-fld., glandulose or glabrous: fls. white; calyx-lobes rather obtuse. May. Asia and N. Amer., Unalaska, Bering Straits.

58. *gemmipara*, Franch. Sts. erect from a long rhizome, 4-5 in. high, branched, the branches rising from pockets, pilose below; the axils with buds: lvs. lanceolate, long-mucronate, entire, pale, shiny and lineolate on the under surface, both surfaces and the margin strigose with white hairs: infl. paniculate-corymbose, borne on a densely glandular fl.-st. which is naked above; pedicels bracteolate at their base: fls. yellow to white; sepals lanceolate, glabrous or glandulose, scarcely or not spreading; petals oblong, obtuse, abruptly attenuate to a long claw, twice as long as the sepals. July-Sept. China.

59. *aizoides*, Linn. (*Leptásea aizoides*, Haw.). Loosely caespitose, 2-6 in. high, with decumbent or ascending, foliose, glabrous or sparsely very short pilose caudicles which are branched from the base: lvs. green or reddish, the lower linear or linear-oblong, mucronate, flat below, above slightly convex, glabrous or more or less rigid-ciliate; the upper rather remote, smaller, oblong, rather obtuse, rarely ovate: infl. 1-fld., often many-fld., racemose, borne near the top of the st. on axillary peduncles: fls. yellow, more or less spotted with orange;

calyx-lobes oblong-triangular, obtuse, spreading; petals oblong, 1-nerved, $1\frac{1}{2}$ times as long as the calyx-lobes. June-Aug. Eu., Asia, arctic Amer., south to Gulf of St. Lawrence, mountains of N. Vt., W. N. Y., and the Lake Superior region. B.B. 2:171; (ed. 2) 2:217. (The Rocky Mt. form has been segregated as *S. Van-Bruntiae*, Small.)—Usually found in stony places where there is trickling water. Very easy to grow and may be divided almost any time. Var. *aurantiaca*, Hort., is a form with the fls. described as of "old-gold passing off to a kind of coppery red." Var. *atrorubens*, Engl. (*S. atrorubens*, Bert.). Lvs. stiffly spinulose-ciliate: fls. rich crimson (Engler says orange-red or cinnamon-colored). Cent. Eu.

60. *cinerascens*, Engl. & Irmscher. Densely caespitose, 2-4 in. high, the caudicles prostrate, rosulate-lvd.: lvs. of the caudicles rather stiff, linear-lanceolate, margin cartilaginous and lax-ciliate or ciliate-spinulose, apex tapering to a persistent awn, under surface shining, whitish; the cauline lvs. lanceolate, rather stiff, aristate, margin densely short, black glandular-pilose: infl. 1-3-fld., on fl.-sts. which are often reddish their whole length and black glandular-pilose as are the pedicels: fls. golden yellow; sepals ovate, subacute, not reflexed; petals obovate, narrowed to a stipitate base, 3-nerved, the lateral nerves bifid. Sept. China.—Rare.

61. *Brunoniàna*, Wall. Fig. 3560. Lax, caespitose, 2-8 in. high, very glabrous, stoloniferous; the stolons wiry, filiform and reddish: sts. erect, slender: lvs. stiffish, light green, becoming gray in age, linear-lanceolate, cartilaginous-mucronate, setose-ciliate; the lowest imbricate, erect and appressed; the upper few and smaller: infl. 1-4-fld. corymbs; the peduncles and pedicels glandulose, the latter 3 or 4 times longer than the fls.: fls. light yellow; calyx-lobes ovate, obtuse; petals oblong, obtuse, 3-nerved, 3-4 times longer than the calyx-lobes. July, Aug. Temperate Himalaya. B.M. 8189.—*Spatularia Brunoniana*, Small, is not this species but a variety of *S. leucanthemifolia*. *S. Brunoniana* spreads freely by means of its runners and likes a moist spot. Not commonly in cult. in Amer. Var. *grandiflora*, Hort., is offered in the trade. Var. *majuscula*, Engl. & Irmscher (*S. majuscula*, Hort.). Larger than the type: sts. 3-8 in. high: infl. composite, 3-9-fld.; the branches $1\frac{1}{4}$ -4 in. long. Sept., Oct. China.

3560. Saxifraga Brunoniana.

62. *flagellaris*, Willd. (*Leptásea flagellaris*, Small). Sts. simple, erect, 1-8 in. high, leafy, densely glandular-pilose: the plant stoloniferous, the stolons bearing a minute bud and roots at their apex: lvs. more or less minute, glandular-pilose, margin glandular-pilose or setose-ciliate; the basal and lower lvs. close together, obovate-oblong; the upper lanceolate: infl. corymbosely 1-10-fld.; the pedicels very short: fls. large, golden yellow; calyx divided beyond the middle or even to the base, the lobes oblong, obtuse, densely glandular-hirsute;

petals obovate-cuneate, the apex obtuse, 5-7-, rarely 9-nerved, 2 or 3 times longer than the calyx-lobes. May-July. Boreal and alpine Eu., Asia, and N. Amer., southward in the Rocky Mts. to Ariz. J.F. 3:237. Gn. W. 25:530.—It requires a moist boggy situation and is difficult to carry through the winter.

Section XI. ROBERTSONIA.

- A. *Lvs. of the rosette obovate or obovate-oblong, attenuate to a flat petiole.*
- B. *Blades of lvs. very glabrous: panicle-branches 1-3-fld. 63. cuneifolia*
- BB. *Blades of lvs. sparsely hirsute: panicle-branches 3-6-fld. 64. umbrosa*
- AA. *Lvs. of the rosette ovate or orbicular; the petiole round or roundish. 65. Geum*

63. *cuneifolia*, Linn., sometimes misspelled *cunifolia*. Laxly caespitose, 4-6 in. high, with slender subligulous caudices: sts. slender, erect, short-glandular and naked; lvs. very glabrous, rather thick, the upper surface dark green and shiny, the lower paler and dull or violet, obovate or subrotund, very obtuse, cuneately attenuate to a long flat ciliate petiole, margin slightly cartilaginously repand-crenate: infl. a loose panicle with 1-3-fld. branches: fls. white; calyx-lobes oblong-triangular, very obtuse; petals oblong, 3-nerved with a yellow spot at the base (occasionally also spotted with purplish red dots). June, July. Mountains of Eu.—There is a form of this species which is grown as *S. Bücklandii*, Hort., which only differs in having 2 or 3 yellow spots on each petal.

Var. *subintegra*, Ser. (*S. apennina*, Bert. *S. cuneifolia* var. *apennina*, Koch. *S. capillipes*, Reichb.). Caudices long, scantily lvd., forming a rosette at their tip: lvs. smaller, retuse, few-dentate, or entire, petiole equaling the blade: sts. few-fld., simple paniculate. Switzerland, Tyrol, Apennines, and Maritime Alps.

64. *umbrosa*, Linn. LONDON PRIDE. ST. PATRICK'S CABBAGE. Loosely caespitose, 6-12 in. high, with subligulous caudices: sts. erect, naked; lvs. forming a dense rosette 6-12 in. across, rather thick, leathery, gray-green, dull shiny, lower surface tinged reddish or violet, oblong or obovate-oblong, sparsely hirsute, very obtuse, attenuate to the ciliate (rarely glabrous) petiole, margin obtusely crenate: infl. laxly paniculate with 3-6-fld., shortly glandulose-hirsute branches: fls. white, varying pink; calyx-lobes oblong, rather obtuse; petals oblong-ovate, 3-nerved, with several red dots at their base and a yellow spot in the middle. June, July. Eu.—A very neat and attractive plant, frequent in European gardens, but rarely seen here. Var. *acanthifolia*, Hort., is offered in the trade. Var. *bellidifolia*, Hort., is offered in the trade. Var. *crassiphylla*, Hort., is offered in the trade. Var. *erösa*, Hort., is offered in the trade. Var. *fölis-variegätis*, Hort., a form with the lvs. variegated. Var. *gracilis*, Hort., is offered in the trade. Var. *marmorata*, Hort., is offered in the trade. Var. *primuloides*, Hort. (*S. primuloides*, Hort.), is described as follows: Will grow in sun, but prefers entire or partial shade. It forms masses of dark green rosettes of primula-like lvs., whence rise a host of slender sts. about 6 in. high, bearing little fls. of a kind of rose-pink (fls. also stated to be bright carmine-rose). Var. *rotundifolia*, Hort., is offered in the trade. Var. *serratifolia*, Don. (*S. serrata*, Sternb. *S. serratifolia*, Mackay), is a form with erect, oblong lvs. whose margins are acutely serrate. Ireland. There is a form of this variety known as *S. umbrosa serrata minor*. Var. *variegata*, Hort., is a form with the lvs. variegated with white.

65. *Geum*, Linn. (*Micranthes Geum*, Small). Six to 12 in. high, with subligulous caudices: sts. nearly naked, erect, glandular-hirsute; lvs. variable, reniform-cordate, margins cartilaginous, crenate, the crenations equal except toward the very top where they are shorter, both surfaces but especially the lower hirsute,

petioles 3-4 times longer than the blade and channeled above: infl. paniculate, the branches 3-6-fld., pedicels slender; fls. white; calyx-lobes oblong, obtuse; petals ovate-oblong, twice as long as the calyx-lobes, with a yellow spot at their base and occasionally with several smaller purple-red dots. May, June. Pyrenees, Ireland and said to occur in Newfoundland.—A species in common cult. abroad and very variable, by some considered as a variety of *S. umbrosa*. Var. *crenata*, Hort., (*S. umbrosa* var. *crenata*, Ser.). Lvs. crenate or crenate-dentate: fls. pink, unspotted. Pyrenees. Var. *crinitum*, Hort., is said to resemble a refined form of *S. umbrosa*. Var. *dentata*, Engl. (*S. dentata*, Link. *S. hirsuta*, Linn. *S. umbrosa* var. *hirsuta*, Hort. *S. umbrosa* var. *dentata*, Hort.). Lvs. rather glabrous or hirsute, orbicular, acute-serrate: fls. white with 1 yellow dot or even several purple dots on each petal (by some said to be unspotted).

Section XII. EUAIZOONIA (CHONDROSEA).

- A. *Fls. white (frequently dotted with red or purple).*
- B. *Margin of the lower lvs. reflexed and crenulate or almost entire.*
- C. *Upper surface of lower lvs. convex. 66. longifolia*
- CC. *Upper surface of lower lvs. sulcate or flat.*
- D. *Surface of lf. sulcate.*
- E. *Lower lvs. more or less spatulate or obovate.*
- F. *Apex of lvs. rather acute: calyx-tube glabrous. 67. lingulata*
- FF. *Apex of lvs. more or less obtuse: calyx-tube glandular.*
- G. *Lvs. obovate-ligulate. 68. catalaunica*
- GG. *Lvs. linear at base, spreading above into a spoon-shaped blade. 69. cochlearis*
- EE. *Lower lvs. linear: the plant 1-3-in. high. 70. crustata*
- DD. *Surface of lf. flat. 71. Hostii*
- BB. *Margin of the lower lvs. not reflexed, serrate.*
- C. *Fl.-sts. paniculate above.*
- D. *Cauline lvs. oblong, obtuse. 72. altissima*
- DD. *Cauline lvs. spatulate or oblanceolate, acute.*
- E. *Calyx-lobes ovate; petals obovate or elliptic.*
- F. *The lvs. spatulate. 73. Aizoon*
- FF. *The lvs. oblong or obovate. 75. cartilaginea*
- EE. *Calyx-lobes lanceolate-elliptic; petals oblong-elliptic. 74. Zelebori*
- CC. *Fl.-sts. paniculate, branching from the base. 76. Cotyledon*
- AA. *Fls. commonly not white.*
- B. *Petals pink or purple (sometimes white or white tinted pink). 75. cartilaginea*
- BB. *Petals yellow, red-orange or copper-colored. 77. mutata*

66. *longifolia*, Lapeyr. One to 2 ft. high: st. erect, densely glandular: lvs. basal, very numerous, forming a thick rosette which is frequently 6-7 in. diam., convex, linear-lanceolate, light or gray-green edged silvery, 6 in. long, base ciliate, margin erose-crenulate: infl. a full, pyramidal panicle, branched from the base, many-fld., everywhere glandulose-pilose: fls. white, sometimes dotted purple toward the center; calyx-lobes ovate or oblong, obtuse; petals obovate, 3-nerved, the midnerve usually bifid toward the apex. June, July. Pyrenees. B.M. 5889. G.C. III. 28:402; 39:149; 52:244, 245. Gn. 66, p. 105; 70, p. 124; 72, p. 142; 76, p. 103. G.W. 10, p. 91. G. 14:347.—This species will grow in any rock crevice and is very showy in lf. and in fl., but it has the unfortunate habit of dying when through flowering. Prop. by seed but care must be taken as it hybridizes very readily. Var. *hybrida*, Hort., is a form which is offered in the trade: grows 18 in. high: fls. white. Var. *magnifica*, Hort., is a form with large rosettes up to

12-14 in. diam. and very profusely fld. panicles which attain a length of 2 ft. and a diam. of 16 in. The fls. are white. G.C. III. 53:390 (as *S. longifolia*). Gn. 77, p. 298; 79, p. 30.

67. *lingulata*, Bell. Fig. 3561. One to 2 ft. high with ascending branched caudices which are covered with appressed vestiges of lvs. and form a cespitose clump: sts. erect or ascending, usually glabrous or sometimes sparsely glandular-pilose, leafy: basal lvs. numerous and rosulate, sulcate above, usually linear-spatulate and rather acute, somewhat ciliate, margin erose-crenulate and crustate with lime; cauline lvs. shorter, the margin cartilaginous and less crustate: infl. a thyrsoid panicle from the middle of the scape or above, the branches slender, corymbose-paniculate at their tip, 3-5-fld., very often secund: fls. small, white; calyx glabrous, the lobes ovate or oblong, very obtuse; petals obovate or obovate-oblong, attenuate toward the base, 3-nerved, 2 or 3 times longer than the calyx-lobes. June, July. S. Eu. B.M. 8434. Gn. 79, p. 188. G.C. III. 49:65, note.—A variable species requiring lime and good drainage. Var.

Alberti, Hort. (*S. Alberti*, Regel & Schmalh.), is probably a hybrid: it has much larger rosettes and the infl. is more spreading: fls. white, heavily spotted red. Turkestan. Var. *australis*, Engl. (*S. australis*, Moric.), usually has longer and broader spatulate lvs. which are nearly flat on the top. Italy and Sicily. Var. *Bellardii*, Hort., equals the type. G.C. III. 54:135. Var. *lantoscana*, Engl. (*S. lantoscana*, Boiss. & Reut.). Lvs. short, blunt, spatulate, more or less attenuate at the base but not so at the apex; margin narrowly crustate. Maritime Alps. G. C. II. 15:109. Gn. 64, p. 61; 73, p. 55. Minor forms of this variety are cult., as *S. lantoscana erecta*, having pure white fls., and *S. lantoscana superba*, having arching plumes

3561. *Saxifraga lingulata*.

of creamy white fls. larger than those of the variety proper.

68. *catalaunica*, Boiss. & Reut. Densely cespitose, 1-2 ft. high: lvs. of the rosette, which grows to be 3 in. diam., erect-spreading, obovate-ligulate, rather obtuse, margin subentire and white-crustate, glabrous, glaucous, subcanaliculate above; the cauline lvs. few, obovate-oblong: infl. a slender-branched cymose panicle borne on an erect few-lvd. fl.-st. with erect bracteolate slender glandular-viscid pedicels, which are longer than the fls.: fls. white; sepals oblong, obtuse, glabrous, longer than the glandular tube of the calyx; petals spatulate-oblong, 3 times as long as the sepals. May, June. Spain. Gn. W. 25:125.—By some considered only a variety of *S. lingulata*.

69. *cochleàris*, Reichb. (*S. lingulata* var. *cochleàris*, Engl.). Six to 9 in. high, densely cespitose, with short much-branched caudices covered below with withered lvs.: lvs. densely rosulate, spreading, $\frac{1}{2}$ -1 in. long, linear at their base, toward the top spreading into a rounded or spatulate blade, glaucous, coriaceous, margin cartilaginous and crustate with lime; the cauline lvs. small, linear, acute, red-brown: infl. paniculate, erect and open, either thyrsoid or subcorymbose, borne on

very slender bright red-brown fl.-sts.: fls. white, $\frac{1}{2}$ - $\frac{3}{4}$ in. diam.; calyx red-brown, the lobes small, ovate, obtuse; petals obovate, apex rounded. June, July. Maritime Alps. Eu. B.M. 6688. G.C. III. 44:245; 51:174. Gn. 74, p. 326. Var. *majior*, Hort., has much larger rosettes of lvs. and taller sprays of fls. It is suggested that it may be of hybrid origin. Var. *minor*, Hort. (*S. Probyni*, Correv.), has minute rosettes of silvery lvs. and much shorter sprays of fls. which are white.—Apparently some of the material grown as *S. valdensis* is referable to this.

70. *crustata*, Vest (*S. incrustata*, Vest). About 1-3 in. high with ascending branched caudices which are covered with appressed vestiges of lvs. and form cespitose clumps up to 4 or 5 in. diam.: sts. ascending, densely glandular-pilose: basal lvs. light gray-green, the lower third pink, sulcate, linear, obtuse, minutely crenulate with the crenatures very close together, crustate with lime, ciliate toward the base; cauline lvs. few, linear-lanceolate, serrate, glandular at base: infl. a scape, racemose from the middle or above, the branches 1-fld. or paniculate 3-6-fld.: fls. yellowish white sometimes purple-dotted toward the center; calyx sparse-glandulose at base, the lobes oblong-triangular with membranaceous margins; petals obovate, base scarcely attenuate, almost 3 times as long as the calyx-lobes. June. Tyrol.—Easy to grow and adapted to a shady location; scarcely known in Amer.

71. *Höstii*, Tausch (*S. elatior*, Mert. & Koch. *S. Aizoon* var. *Höstii*, Hort.). Cespitose, 6-18 in. high: sts. erect, rather stout and glandular-pilose: basal lvs. numerous, rosulate, rather erect, lingulate with an obtuse apex and ciliate base, margin crenulate, the crenatures truncate; cauline lvs. oblong, rather obtuse, crenate-serrate; bracts oblong-linear, glandular ciliate: infl. a scape, paniculate above the branches, elongated, naked and densely glandular-pilose; the pedicels densely short-glandular: fls. white, often with numerous purple dots toward the center; calyx-lobes ovate-triangular; petals oblong or obovate-oblong, double the length of the calyx-lobes. May-Aug. Mountains of Cent. Eu.—A strong grower and said to produce offsets very freely and in this way spread rapidly. Var. *rhætica*, Engl., also spelled *rhätica* (*S. rhætica*, Kerner). Basal lvs. linear-lingulate, apex rather acute: petals obovate-oblong, white with numerous purple dots above the middle. Mountains of Austria.

72. *altissima*, Kerner (*S. Höstii* var. *altissima*, Hort.). Fig. 3558. Cespitose, 1-2 ft. high: sts. erect, stout, glandular-hirsute: lvs. thick, the basal spreading, broad, tongue-shaped, rather acute, base ciliate, margin serrate, serratures acute and cartilaginous; cauline lvs. oblong, rather obtuse, serrate; bracts oblong-linear or linear, obtuse and glandular-pilose ciliate: infl. a scape racemosely paniculate above, the branches about 10-fld. and densely glandular-pilose; pedicels densely short-glandular: fls. white, their base greenish and purple-dotted toward the center; calyx-lobes ovate, obtuse, cartilaginous margined; petals elliptic, 3-nerved, twice as long as the calyx-lobes. Tyrol.—Very closely allied to *S. Höstii*, possibly not specifically distinct. Little known in Amer. outside fanciers' collections.

73. *Aizoon*, Jacq. (*Chondrosea Aizoon*, Haw.). Fig. 3562. Perennial, cespitose, 4-20 in. high: sts. erect, foliose: basal lvs. curved, thick, rather flat above, smooth, the base ciliate, margin serrate, many-pored, more or less crustate with lime, serratures cartilaginous at the apex and antorsely acuminate; cauline lvs. smaller, cuneate or spatulate, base glandular-ciliate: infl. a scape, corymbose-racemose, corymbose-paniculate or paniculate above, the branches 3-5-fld., more or less glandular-pilose, rarely glabrous: fls. cream-colored, commonly purplish red spotted in the center; calyx-lobes ovate; petals obovate or elliptical, 3-5-nerved

almost twice as long as the calyx-lobes: fr. globose. June, July. Alpine and boreal parts of Eu. and Asia, in N. Amer. from Greenland and Lab. to Sask., locally south to Nova Scotia, New Bruns., mountains of N. Vt., and Lake Superior. J.H. III. 69:135.—A very variable alpine plant, much tufted and forming small dense rosettes. *S. Pórtæ*, Stein, from Italy has white fls. and is apparently only a minor variation of *S. Aizoon*. Var. *ambigua*, Hort., is offered in the trade. Var. *atropurpurea*, Hort., is said to have slender branching sts. and rose-purple fls. Var. *balcàna*, Hort., also spelled *balkàna* (*S. balcàna*, Hort.), is a form with close rosettes of medium size and rather flat white fls. with larger red spots than usual (fls. reported as sometimes pale pink). Balkan Mts. Var. *baldensis*, Farrer, with ash-gray lvs., which are short, thick and markedly dentate; their apex rounded: the young shoots glossy, blood-crimson: fls. whitish. N. Italy. Var. *brevifolia*, Hort., with white fls. is offered in the trade. Var. *bulgàrica*, Hort., has rosy spotted fls. Var. *californica*, Hort. (*S. californica*, Hort.), with white fls. must not be confused with *S. californica*, Greene (*Micranthes californica*, Small), a species of Section Boraphila, closely related to *S. virginensis* which is probably not in cult. Var. *Churchillii*, Hort., with pointed gray lvs. in stiff rosettes. Var. *cultrata*, Hort., is offered in the trade. Var. *dùbia*, Hort., is offered. Var. *erecta*, Hort., is offered in the trade. Var. *flavescens*, Hort., is a free-growing decorative form with clear lemon-yellow fls. produced in good spikes. Not to be confused with *S. flavescens*, Hort. (*S. media* × *S. aretioides*), which is apparently scarce in cult. Var. *intacta*, Engl. (*S. intacta*, Willd.), has beautiful white, unspotted fls. *S. intacta* major is the cultural name of a larger form, about 6 in. high. *S. intacta* minor is the cultural name of a dwarf form. Var. *lagaveana*, Hort., also known as *La Graveana* and *La Ga Dauphane*, is a miniature plant with tiny silvery rosettes and ruddy sts. 6 in. high, bearing 4-6 fls. on each st.:

fls. creamy white, thick and wax-like; the buds globular and pink-tinted. Var. *lùtea*, Hort., has the lvs. longer, the rosettes more open, and the fls. deeper yellow than those of var. *flavescens*; fls. at first primrose-yellow changing to creamy yellow. Var. *Mályi*, Hort. (*S. Mályi*, Schott, not Hort.), is one of the tallest forms, with good-sized rosettes. Var. *màjor*, Koch (*S. Aizoon* forma *robusta*, Engl.), has oblong-linear lvs. which are not much broader at the apex. Var. *mínima*, Hort., is a diminutive plant that clings tightly to the rock faces and looks almost like a gray moss: fls. white. Var. *minor*, Koch, has oblong-obovate lvs. shorter than the type. Var. *notàta*, Hort. (*S. notàta*, Schott), has small silver-margined lvs. and white fls. Var. *paradoxà*, Hort., is a form with long bluish lvs., their margins with silvery serratures: fls. white. Engadine.

Gn. 74, p. 463. See *S. paradoxa* in suppl. list. Var. *pectinàta*, Hort. (*S. pectinàta*, Schott, Nym. & Kotschy), has narrow lvs. with blunt teeth and conspicuous silvery margins forming small rosettes: the fls. are small, of a nice white and spotted with red.

Var. *recta*, Ser., in part (*S. recta*, Lapeyr, in part. *S. Aizoon* forma *gracilis*, Engl. *S. carinthiaca*, Schott, Nym. & Kotschy), has lvs. which are spatulate-linear, slightly dilated toward the apex, narrowly and also deeply serrate: the sts. laxly paniculate from the middle and above; the branches 1-3-fld.; fls. white. Var. *rosea*, Hort., is similar to the type, but has bright pink fls. Var. *rosulàris*, Hort. (*S. rosulàris*, Schleich.), has finely incurved rosettes and large sprays of white fls. Var. *Stabiàna*, Hort. (*S. Stabiàna*, Ten.), has large rosettes and sprays of creamy white fls. Not very distinct from the type. Var. *Sturmiàna*, Hort. (*S. Sturmiàna*, Schott, Nym. & Kotschy), is a good-sized form with flattish rosettes, probably referable to the type-form.

74. *Zelébóri*, Schott. Sts. densely and longly glandular-pilose toward the base, decreasingly so toward the apex: lvs. of the glaucous rosette, which is 1½ in. diam., almost linear, acute, very minutely serrate, the serratures inverted-acute and contiguous (the lowest less so); cauline lvs. shorter, oblanceolate, acute, glabrous, above the middle sharply serrate (serratures rather remote), apex appressed serrate-crenate: fls. white, not dotted; calyx glabrous, the lobes lanceolate-elliptic, obtuse; petals oblong-elliptic, not clawed, obtuse, apex rounded. Serbia.—Plants under this name are offered in English trade-lists, but the species is not included in any of the recent treatments of Saxifraga. The above description is taken from Schott's original. Whether the plant offered is the same is undetermined. Probably a variation of *S. Aizoon*.

75. *cartilaginea*, Willd. (*S. Kolenatiàna*, Regel). Six to 9 in. high: st. sparingly glandulose, few-lvd.: lvs. rosulate, oblong or obovate-oblong, acute or acuminate; the margin cartilaginous toward the base, serrate, serratures antrorsely subacuminate, toward the apex subcrenate, crenatures truncate: infl. a scape, racemose or paniculate above, the branches 1-5-fld.: fls. white, rose, or purple; calyx-lobes ovate-triangular, rather acute; petals obovate, 2-3 times longer than the calyx-lobes. June-Aug. Caucasus region and Asia Minor.—*S. Kolenatiàna* has been kept distinct by some but seems to differ only in the slightly more acute serratures of the lvs. In gardens it is more common under this name. A somewhat larger form is known as *S. Kolenatiàna* major, Hort.

76. *Cotylèdon*, Linn. Tufted, 6-24 in. high: st. erect: lvs. thick and fleshy, basal lingulate or obovate-lingulate, short-apiculate, the base softly fimbriate, margin serrate, serratures cartilaginous, at their apex antrorsely acuminate; cauline lvs. lingulate-lanceolate, the lower part glandular-ciliate, the upper serrulate; bracts linear, acute and glandular: infl. a scape, paniculate from the base, the panicle composite, pyramidal, glandular-pilose all over, the branches paniculate from their middle, 5-15-fld.: fls. white, occasionally tinged rose; calyx-lobes longer than the glandulose tube, oblong-acute; petals obovate-cuneate, 3-5-nerved, midnerve mostly bifid, 2-3 times longer than the calyx-lobes. May-July. Mountains of Eu. G. 11:209; 34:781; 35:541. G.W. 12, p. 471.—Easy to prop. as it makes a large number of side shoots which root quickly when potted. Var. *icelàndica*, Maxwell (*S. icelàndica*, Hort.), is the largest form of the species and produces numerous offsets. The rosettes are very large and flat and the ligulate lvs. are usually bronzed and leathery. G. 35:707. Var. *pyramidalis*, Ser. (*S. pyramidalis*, Lapeyr, not Ten. *S. nepalensis*, Hort.), is a very robust form from 2-4 ft. high when in fl. The rosettes are large and glaucous and the fls. very numerous in a large pyramidal panicle, white, speckled with crimson. May, June. G.C. III. 53:389. G. 35:163. Gn. 61, p. 393; 74, p. 266; 78, p. 349. Var. *pyrenàica*, Hort., has more pointed lvs. and shorter plumes of white fls. Pyrenees.

77. *mutàta*, Linn. Six to 12 in. high: rhizome thick, horizontal or oblique: sts. ascending, foliose: basal lvs.

3562. Saxifraga Aizoon. (×½)

lingulate, rosulate; margin cartilaginous, densely fimbriate below, entire or obsoletely serrulate above with many little indistinct pits; cauline lvs. lingulate-spatulate, very obtuse: infl. racemously paniculate from the base or middle of the scape, this and the peduncles glandular-hirsute: fls. yellow, red-orange or copper-colored; calyx-lobes oblong-triangular, sparsely glandular-pilose or glabrous; petals linear-lanceolate, acute, 3-nerved, narrower than and twice the length of the calyx-lobes. July, Aug. Mountains of Cent. Eu. B.M. 351.—Suitable for rather heavy shade. The plant dies after flowering. Said to be biennial.

Section XIII. KABSCHIA.

- A. Caudicle lvs. broader or as broad above the middle as below it.
- B. Petals as long as or slightly longer than the calyx-lobes: fls. reddish or purplish. (The following four species are very closely related.)
- G. Infl. spreading, branched.
- D. Lower lvs. spatulate-lingulate, the tip somewhat recurved... 78. *media*
- DD. Lower lvs. spatulate-oblanco- late, the tip spreading..... 79. *Stribnyi*
- CC. Infl. spicate or nearly so.
- D. Rosette lvs. spatulate-lingulate, their apex rounded mucronate. 80. *Grisebachii*
- DD. Rosette lvs. linear-lanceolate, their apex acute or acutish... 81. *Friderici-Augusti*
- BB. Petals 2-4 times as long as the calyx-lobes.
- C. Fls. yellow.
- D. Infl. 1-3- (rarely cymosely 3-5) fld.: basal lvs. gray-green.... 82. *aretioides*
- DD. Infl. 4-6-fld., in a close head: basal lvs. green or somewhat glaucous..... 83. *Ferdinandi-Coburgi*
- CC. Fls. not yellow (sometimes cream-colored), usually white, sometimes rose.
- D. The petals obovate to cuneate: basal lvs. not recurved at tip.
- E. Lower lvs. deeply keeled, acute. 84. *scardica*
- EE. Lower lvs. flat or slightly keeled, blunt.
- F. Petals obovate, 3 times as long as the obtuse calyx-lobes.
- G. Lvs. spatulate, light gray-green..... 85. *Rocheliana*
- GG. Lvs. obovate-cuneate, shorter and broader than the preceding... 86. *marginata*
- FF. Petals elliptic-spatulate, twice as long as the acute calyx-lobes..... 87. *Boryi*
- DD. The petals rounded-obovate: basal lvs. more or less recurved.
- E. Recurved only at the tip of lf.
- F. Infl. 1-fld.: fls. pale or rosy lilac..... 88. *lilacina*
- FF. Infl. 2-4-fld.: fls. white... 89. *squarrosa*
- EE. Recurved from the base or middle of lf.
- F. Basal lvs. linear-oblong, rather acute..... 90. *caesia*
- FF. Basal lvs. spatulate-linear, obtuse..... 91. *valdensis*
- AA. Caudicle lvs. narrowed above the middle.
- B. Fls. white.
- C. Petals obovate, base strongly cuneate-attenuate.
- D. Cauline lvs. acute: infl. cymose-racemose, 1-3-fld..... 92. *tombeanensis*
- DD. Cauline lvs. long-mucronate: infl. corymbose-paniculate, 3-7-20-fld..... 93. *Vandellii*
- CC. Petals obovate-subround..... 94. *Burseriana*
- BB. Fls. yellow or yellowish green.
- C. Stamens as long as the petals.... 95. *sancta*
- sc. Stamens decidedly longer than the petals..... 96. *juniperifolia*

78. *mèdia*, Gouan (*S. calyciflora*, Lapeyr.). Cespitose, 2-3 in. high, with short densely foliose caudicles: sts. erect, leafy, densely glandular-pilose: basal lvs. imbricated, stiff, gray-green, reddish toward their base, the rosettes flattened-depressed, spatulate-lingulate, apex acute or obtuse, margin narrowly cartilaginous, ciliate below, 7-11 pits near the margin when old; cauline lvs. spatulate, cartilaginous, and densely glandular-hirsute on both surfaces except toward the tip which is mucronate and glabrous: infl. cymose-paniculate or racemose; peduncles and calyx purplish and densely glandular: fls. flesh-colored or purplish, at length dark blue; calyx-lobes ovate; petals erect, obovate, about 3-5-nerved, scarcely longer than the calyx-lobes. June, July. Pyrenees. Gn. 78, p. 108.

3563. *Saxifraga Grisebachii*.

79. *Stribnyi*, Velen., also spelled *Stribnyi*, *Stribnyi*, and *Stribnyi* (*S. porophylla* var. *Stribnyi*, Velen.). Cespitose, 4-5 in. high, with short, densely foliate caudicles: fl.-sts. erect, branched, sparsely leafy, spreading, glandular-pilose: lower lvs. rosulate, spreading, sessile, spatulate-oblanco- late, apex submucronate, fleshy, above intramarginally pitted, carinate below, margin narrowly cartilaginous toward the base, sparingly ciliate; cauline lvs. oblong-spatulate, subacute, green, sometimes reddish toward the apex, margin below glandular-ciliate, both surfaces sparsely glandular-pilose: infl. cymose, branches spreading or slightly recurved up to 1½ in. long; the pedicels up to ½ in. long, spreading, glandular-pilose: fls. nodding, carmine, ½ in. diam.; calyx campanulate, reddish purple and densely glandular-pilose outside, the lobes subequal, oblong-ovate, apex rounded, glandular-pilose outside; petals suberect, broad-spatulate, apex obtusely dentate, glabrous, about the same length as the calyx-lobes. Feb.-April. Bulgaria. B.M. 8496. G.C. III. 46:195. Gn. 73, p. 212. G.L. 24:366.—A hardy species with grayish foliage and open infl.

80. *Grisebachii*, Degen & Doerfl. (*S. mèdia* var. *montenegrina*, Hort.). Fig. 3563. Cespitose, 4-6 in. high, with short, densely foliose caudicles: fl.-sts. erect, leafy, densely spreading, glandular-pilose: lower lvs. imbricate, spreading, sessile, spatulate-lingulate, apex rounded-mucronate, above numerous intramarginal small pits, below carinate, margin cartilaginous, slightly ciliate toward the base; cauline lvs. spreading, oblong-spatulate, reddish, the tip contracted into a green mucron, both surfaces densely glandulose-pilose except the mucron: infl. racemose or subsapicate; pedicels much shorter than the bracts: fls. purple or crimson; calyx reddish purple, densely glandular-pilose, the lobes unequal, oblong-elliptic, apex rounded; petals erect, elliptic-lanceolate, ciliate below. March. Albania and Macedonia. B.M. 8308. G. 33:513. G.C. III. 33:123. G.M. 46:119. Gn. 63, p. 180; 72, p. 215; 77, p. 120; 79, p. 31. G.W. 12, p. 470. J.H. III. 46:207.—Hardy in England.

81. *Friderici-Augusti*, Bias., also spelled *Frederici-Augusti* and *Federici-Augusti* (*S. porophylla*, Boiss., not Bertol. *S. sempervivum*, Koch. *S. thessálica*, Schott.). Cespitose, 2–6 in. high with short densely foliate caudices: sts. erect, densely glandular: basal lvs. forming a flattened rosette, linear-lanceolate, acute or acutish, glabrous, flat, entire, often ciliate at the base, remotely pitted near the margin; cauline lvs. spatulate, glandular: infl. a spike-like raceme, dark purple; pedicels all about equal and shorter than the bracts: fls. violet-purple; calyx glandular, the lobes ovate, obtuse; petals cuneate-spatulate, scarcely longer than the calyx-lobes. April. Dalmatia, Serbia, Greece, and N. E. Asia Minor. G. 35:761.—This species has been treated as *S. media* var. *Friderici-Augusti*, Engl., but differs from that species in the narrower lvs. and more spicate raceme. It has also been referred to *S. porophylla*, Bertol., as a synonym: the latter is said to have lingulate basal lvs. with obtuse apex, and flesh-colored petals. The distinctions between *S. Friderici-Augusti* and *S. porophylla* seem to be very unsatisfactory. Much of the material cultivated as *S. Friderici-Augusti* is really *S. apiculata*.

82. *aretioides*, Lapeyr. Cespitose, about 2 in. high, with woody, densely imbricate-foliose caudices: sts. short and leafy, glandular-hirsute: lower lvs. sulcate, weakly keeled, leathery and stiff, both sides gray-green but violet at the base of the under surface, linear-lingulate, apex rather obtuse, margin narrowly cartilaginous, the lower portion ciliate and near the margin are 7–9 pits noticeable with age; cauline lvs. linear-spatulate, glandular-hirsute and cartilaginous except the apical portion: infl. terminal, 1–3-fld., rarely cymose, 3–5-fld.; the pedicels and calyx glandular: fls. golden yellow, calyx-lobes ovate and acutish; petals broad-obovate, 5–7-nerved, more than twice as long as the calyx-lobes. April–July. Mountains of Eu. B.M. 5849.—Should be planted on a shady ledge where it will obtain plenty of moisture. Little known in Amer. Var. *primulina*, Hort., grows about 1½ in. high; the peduncles are paler green than the type; the fls. are true primrose-yellow and the petals are usually well rounded and fairly well imbricated.

83. *Férdinandi-Cöburgi*, Kell. & Sünderm. Cespitose, about 2 in. high, with columnar foliose branched caudices: sts. with 9–12 lvs., glandular-hairy as is the calyx and tinted red-brown: lower lvs. somewhat glaucous, up to ½ in. long, little narrowed toward the top, margin fine-hairy below, apex thickened and incurved-pointed; cauline lvs. 9–12 in number: infl. close heads of 4–5 (5–6) large, rich yellow fls.: petals ⅝ in. long, ½ in. wide, strongly narrowed toward the base. March, April. Macedonia.

84. *scárdica*, Griseb. (*S. scarélica*, J. Wood). Cespitose, 3–4 in. high, with woody, very densely foliate caudices: sts. ascending and glandular-pilose: basal lvs. leathery, stiff, light gray-green, pale violet toward the base, oblong acute, spreading, upper surface concave, lower convex-carinate, lower margin indistinctly serrulate or ciliate, upper cartilaginous, entire, when old there are 9–15 pits near the margin; cauline lvs. few, lanceolate, acute, glandular-hirsute except the apical portion, cartilaginous and glandular-hirsute: infl. corymbose, 3–11-fld.: fls. white, ivory-white, or pale rose-red; calyx-lobes ovate, acutish; petals obovate-cuneate, 5-nerved, more than twice the length of the calyx-lobes. June, July. Orient. B.M. 8243. Gn. 65, p. 323; 69, p. 231. S. E. Eu.—Readily distinguished from *S. Rocheliana* by its keeled and more pointed lvs. The species itself is hard to grow and consequently is rare in cult. The plant grown as *S. scárdica vera* is the true *S. scárdica*, Griseb. G. 34:199. Var. *obtusa*, Sprague, differs from the type in having subacute to obtuse lower lvs. with fewer pits, fl.-sts. 1–3-fld. and green, and the calyx-lobes obtuse and less pubescent.

March. Macedonia. B.M. 8058 (as *S. scárdica*). G. 32:529.

85. *Rocheliána*, Sternb., also incorrectly spelled *Rochelliana*. Very densely cespitose-cushioned, forming mats 8–12 in. diam., 2–3 in. high, with more or less elongated, densely imbricated, foliose, often columnar caudices: lower lvs. stiff, shiny light gray-green above, violet below, densely aggregated, horizontally spreading, spatulate, obtuse, very smooth, flat above, rather convex below the base, ciliate, 7–9 pits near the margin noticeable when old; cauline lvs. few, obovate-spatulate, cartilaginous and glandular-pilose except the apical portion: infl. corymbose-paniculate, 3–9-fld., borne on an erect purple-red glandular-pilose fl.-st.; pedicels erect, these and calyx glandulose and pale green: fls. white; calyx-lobes ovate, obtuse, erect; petals obovate, clawed-attenuate, 7-nerved, thrice the length of the calyx-lobes. April–July. E. and S. E. Eu.—Flowers freely. Var. *coriophylla*, Engl. (*S. coriophylla*, Griseb., also spelled *coryophylla*). The lower lvs. smaller, less horizontally spreading, oblong, obtuse, fewer pitted: fls. ivory-white. Bosnia and N. Albania.

86. *marginata*, Sternb. Cespitose, about 3 in. high, with caudices which are subnaked below or short-columnar, woody and leafy: lower lvs. obovate-cuneate, obtuse, the base ciliate, the upper margin cartilaginous; cauline lvs. cartilaginous and glandular-pilose excepting the apical portion: infl. corymbose, 5–7-fld., borne on erect fl.-sts., these as well as the pedicels and calyx being black-glandular-pilose: fls. white; calyx-lobes ovate-oblong, obtuse; petals obovate, attenuate at base, 5–7-nerved, 3 times the length of the calyx-lobes. March–June. S. Italy. B.M. 6702. Gn. 77, p. 206; 79, p. 294. G.L. 18:117.—Suitable for sunny ledges and rocky crevices, but requires lime and good drainage. Some of the material cult. under this name may be *S. Boryi*.

87. *Böryi*, Boiss. & Heldr. (*S. marginata*, Bor. & Ch., not Sternb.). Cespitose-cushioned, about 1½ in. high, with densely imbricate-foliose caudices which are elongated and columnar: lower lvs. oblong-spatulate, obtuse, glabrous, erect-spreading, subcoriaceous, flat above and subcarinate below, margins ciliate at base or others entire, remotely pitted near the margin; cauline lvs. few, minute and glandulose: infl. corymbose, 3–5-fld., borne on erect glandular fl.-sts.: fls. white; calyx glandular, the lobes triangular-ovate, acute; petals elliptic-spatulate, twice the length of the calyx-lobes. April–July. S. E. Eu.—Thrives in a sunny location. Closely allied to *S. marginata* but differs in having smaller lvs., acute calyx-lobes and shorter and narrower petals.

88. *lilácina*, Duthie. Cespitose, ½–1 in. high, with numerous very densely foliose, columnar caudices: lvs. rosulate, oblong, obtuse, recurved and thickened toward the apex, sparsely ciliate at the base, margin cartilaginous and incurved, 3–5-pitted toward the apex; cauline lvs. 1–2, alternate, erect, linear-oblong or spatulate, obtuse, glandular, half-clasping at base: infl. 1-fld., borne on glandular-pubescent fl.-sts. which are lilac: fls. about ½ in. diam., pale or rosy lilac with a purple center; calyx ½ in. long, glandular-pubescent, the lobes ovate-oblong, obtuse; petals ½ in. long, obovate-rotund, cuneate at the base, the margins undulate. March, April. W. Himalayas. G.C. III. 35:290. Gn. 65, p. 250.—The plant is very dwarf, and is grayish green in color, though the lf.-tips are dark green.

89. *squarrosa*, Sieber. Very densely cespitose, about 3 in. high, with woody, subcylindrical caudices which are very densely imbricate-leafy: lvs. of the caudices dark green, imbricated, erect, becoming curved-spreading at the apex, linear-lanceolate, obtuse, submucronulate, very narrowly cartilaginous margined, at the base fimbriate, the back convex and obtusely carinate above, marked with 7 pits, crustate with lime when young;

cauline lvs. linear, slightly carinate, 3-5-pitted: infl. 2-6-fld., borne on very slender sts. which are glandular below and sparsely glandular or glabrous above: fls. white; calyx glabrous, the lobes ovate, obtuse, slightly cartilaginous at their tips; petals subrotund-obovate, 5-nerved, the nerves straight, twice as long as the calyx-lobes. May-Aug. Mountains of Eu. G.L. 28: 185.—A small species useful in alpine-gardens in a sunny spot. It likes to be firmly wedged between stones with sufficient earth for its root-development.

90. *cæsia*, Linn. (*S. recurvifolia*, Lapeyr.) Dwarf, cespitose, about 3 in. high, with curved, woody, imbricate-folios caudicles: lvs. of the caudicles densely congested, gray or light gray-green, arched-recurved from the base, linear-oblong, rather acute, near the margin 7-pitted, fimbriate from the base to the middle, convex and obtusely carinate dorsally, crustate with lime when young; cauline lvs. narrowly spatulate, slightly carinate, 3-5-pitted, glandular-ciliate at the base: infl. subcorymbose, 2-6-fld., borne on glabrous or sparsely glandular-pilose, green fl.-sts.: fls. snow- or cream-white; calyx-lobes ovate or obtuse, sparsely glandular, scarious at their apex, otherwise ciliate; petals obovate, 3-5-nerved, lateral nerves bowed or straight, almost 3 times as long as the calyx-lobes. June-Aug. Mountains of Eu. L.B.C. 5:421. Var. *major*, Don, has the sts. more robust, taller, and strongly villous: the rosettes of gray lvs. are rather larger than the type and the milk-white fls. are larger. May, June.

91. *valdënsis*, DC. Cespitose, 1-3 in. high, with short, woody, imbricate-folios caudicles: sts. erect, glandular: lower lvs. densely congested, gray-green, light violet on the under side, erect, recurved from the middle, spatulate-linear, obtuse, dorsally convex and obtusely carinate, 9-pitted near the margin, crustate with lime, fimbriate from the base to the middle; cauline lvs. spatulate, 3-5-pitted, glandular: infl. compactly corymbose, 6-10-fld., borne on dark purple fl.-sts.: fls. white; calyx-lobes ovate, very obtuse, glandular; petals obovate, 3-5-nerved, almost 3 times as long as the calyx-lobes. May-July. Mountains of Cent. Eu. —Resembles a minute *S. lingulata* var. *cochlearis*.

92. *tombeanënsis*, Boiss. (*S. diapensioides* var. *tombeanënsis*, Hort.). One to 2 in. high, with numerous very densely folios, columnar, erect, or ascending caudicles: lvs. of the caudicles imbricate, erect, incurved at their tip, ovate-lanceolate, subulate, 3-cornered, apex mucronulate, near the margin very slightly cartilaginous, very minutely serrulate, 5 minute pits are noticeable when old; cauline lvs. linear-lanceolate with the exception of the apical part, narrowly cartilaginous-marginate, acute, glandular-pilose: infl. cymose-racemose, 1-3-fld., borne on erect sts., these as well as the peduncles and calyx densely slender glandular-pilose: fls. white; calyx-lobes oblong-triangular; petals broadly obovate, strongly cuneate-attenuate toward the base, many-nerved, 3 or 4 times as long as the calyx-lobes. April. S. Tyrol and N. Italy.

93. *Vandellii*, Sternb. About 2 in. high, the caudicles very closely imbricate-folios and also strongly congested: lvs. of the caudicles leathery, very stiff, light green, erect, lanceolate, acute, stiffly mucronate, 3-cornered, 5-7-pitted (noticeable when old) near the cartilaginous margin, fimbriate at the base, when young crustate with lime; cauline lvs. linear-lanceolate, glandular-pilose except the long-mucronate apex: infl. corymbose-paniculate, 3-7-20-fld., borne at the top of erect fl.-sts.; peduncles and calyx covered with spreading, glandular hairs: fls. white with reddish veins; calyx-lobes ovate-lanceolate, acute; petals erect, obovate, strongly cuneate-attenuate toward the base, many-nerved, 3-4 times as long as the calyx-lobes. April-Aug. Tyrol. G.C. III. 44:71; 57:238. Gn.W. 25:458.—Best suited to rock-fissures as it has deep woody tap-roots; also requires lime.

94. *Burseriàna*, Linn. Cespitose, 2-4 in. high, with densely imbricate-folios caudicles: lvs. of the caudicles densely congested, stiff and prickly, fresh gray-green, when old light brown, 3-cornered, linear-subulate, acuminate, stiffly mucronate, 7-pitted (noticeable when old) near the cartilaginous margin, short-fimbriate at the base, crustate with lime when young; cauline lvs. smaller and appressed: infl. usually 1-fld. on glandular-pilose, remotely leafy fl.-sts., these and the calyx frequently dark purple: fls. white, the veins often colored, showy; calyx-lobes ovate, rather acute, tube glandular-hirsute; petals obovate-subrotund, base somewhat clawed, spreading. Jan. to May or June. Mountains of Cent. Eu. G. 1:793; 19:59. G.M. 54:103. Gn. 71, p. 187; 74, p. 55; 75, p. 165; 78, p. 116. G.L. 24:44; 25:392. G.C. III. 55:151. J.H. III. 69:137. G.W. 7, p. 433; 12, p. 470.—One of the earliest flowering and one of the most commonly cult. Very variable and the parent of many hybrids. Some of the varieties in cult. are: Var. *Böydii*, Hort., equals both *S. Böydii* and *S. Böydii* var. *alba*, Var. *crenata*, Hort., a form with crenate petals, close to var. *major*. G. 36:289. Var. *élegans*, Hort., equals *S. Irvingii*. Var. *glória*, Hort., is a large-fld. form with fl.-sts. $1\frac{1}{2}$ in. high: peduncles rich red: fls. pearly white, of a satiny texture, over 1 in. diam.; petals with crimped edges. G. 31:252; 35:177; 36:288. Gn. 78, p. 81. G.M. 50:213. Var. *grandiflora*, Hort., is practically identical with var. *gloria*. G.M. 57:185. Var. *macrantha*, Hort., has minute rosettes which are very dense and form a cushion-like mound: fl.-sts. reddish, 1 in. high: fls. white and saucer-like. April. Var. *magna*, Hort., is distinguished from var. *major* by having a very densely tufted habit: lvs. spiny, glaucous: peduncles 3 in. high and 1-fld., reddish: fls. white, more than 1 in. across, even larger than var. *gloria*. G.C. III. 47:164. Var. *magnifica*, Hort., grows about $1\frac{1}{2}$ -2 in. high with small dense rosettes of subulate gray lvs.: scape 1-fld.: fls. have huge, orbicular petals which are white and deeply crenate and the disk is of a paler yellow than that of var. *major*. April, May. Gn.W. 20:203; 26:251. Var. *major*, Hort., is less cushion-like in habit, has pronounced silvery rosettes twice as large as the type, reddish scarlet fl.-sts. 3 in. high, and fls. about 1 in. diam. with crimped white petals. Feb. Austrian Alps. G.C. II. 21:141. G. 31:253. Gn. 63, p. 75. Var. *minima*, Hort., is said to have diminutive white fls. Var. *minor*, Hort., is mentioned in connection with *S. Pauline* as one of the parents of that hybrid. Var. *rosea*, Hort., equals *S. Irvingii*. Var. *speciosa*, Hort., has bright red scapes bearing solitary fls. which are larger and later than the type; the petals are pure white, broad and almost round. Var. *tridentina*, Jenkins (var. *tridentata*, Hort.), is more tufted than var. *major*, the fl.-sts. more richly scarlet and the fls. less notched at the margins, the petals reflexed, white. Jan., Feb. Dolomites. G. 37:379.

95. *sáncta*, Griseb. Cespitose, about 2 in. high, the caudicles densely leafy: lvs. rigid, prickly, dark green, the lower imbricate, spreading, lanceolate, acuminate, stiffly mucronate, the entire margin ciliate-denticulate, carinate, 3-5 minute pits (noticeable when old) near the cartilaginous margin; cauline lvs. lanceolate, mucronate: infl. corymbose-paniculate from the middle or upper part of the glabrous sts.: fls. small, light or rich orange-yellow; calyx glabrous, lobes ovate, entire and obtuse; petals spatulate-oblong, 3-nerved, the lateral nerves bowed. June. Macedonia.—Fine for covering moist stony banks in the rock-garden. Var. *speciosa*, Hort., is offered in the trade as a form with fine yellow fls.

96. *juniperifolia*, Adams (*S. juniperina*, Bieb.). Cespitose, 1-2 in. high, the woody caudicles densely imbricate-folios: lvs. of the caudicles green, very stiff and prickly, erect, appressed, subulate, a little broader at the ciliate base, stiffly mucronate, toward the middle

and apex entire, almost 3-cornered, with 5-7 minute pits noticeable when old near the cartilaginous margin; cauline lvs. light green, long-ciliate at the base: infl. racemose or spicate-capitate, few-fld., borne on leafy, short, crisply villous fl.-sts.: fls. small, yellow; calyx light green, tube villous, lobes ovate, acute, mucronate, pectinately ciliate; petals oblong-spatulate, 3-nerved, slightly longer than the calyx-lobes. May-July. Caucasus.—Little known outside of botanic-garden collections.

Section XIV. PORPHYRION (ANTIPHYLLA).

- A. Lvs. oblong-obovate, their apex flat or recurved.
 B. Infl. 1-fld.: petals obovate-oblong, 5-nerved.....97. *oppositifolia*
 BB. Infl. 2-9-fld.: petals lanceolate, 3-nerved.....98. *biflora*
 AA. Lvs. oblong-lanceolate, recurved from their middle.....99. *retusa*

97. *oppositifolia*, Linn. (*Antiphylla oppositifolia*, Small). Caudicles procumbent and much branched, 6-8 in. long, the branches densely cespitose, the flowering ones erect, about 6 in. high at most, glabrous and 1-fld.: lvs. opposite, stiff, dark green, gray-tipped, the lower and those of the sterile branches imbricate in 4 rows, the upper rather remote, oblong or obovate, apex spreading-recurved, obtuse, thickened, 1-3-pitted, 3-cornered-carinate below: fls. showy, violet or lilac, sometimes rose-purple, terminal; calyx-lobes ovate, obtuse; petals obovate-oblong, 5-nerved, 3 times as long as the calyx-lobes. March-June, rarely Aug. Rocks, alpine and boreal parts of Eu., Asia, and N. Amer., south to Gulf of St. Lawrence, mountains of N. Vt., Mont., and Idaho. L.B.C. 9:869. G.C. III. 49:117. Gn. 71, p. 179; 76, p. 603; 78, p. 57.—An excellent little rock-plant, making a sedum-like mat, the foliage of a purplish cast. Many variations in cult. Var. *alba*, Hort., has a compact habit, very dark green lvs., and starry white fls. Var. *coccinea*, Hort., has fls. of a richer shade of purple than the type. Var. *grandiflora*, Hort., is a form with elongated branches larger, obovate-rotund petals which are attenuate only at the clawed base and 7-9-nerved: the fls. are large and rosy purple. Pyrenees. Var. *latina*, Farrer (*S. latina*, Hayek), is a form with very small compact foliage and good-sized, soft rosy purple fls. whose petals are obovate, rather acute, and 5-nerved. Italy. Var. *majior*, Hort., has creeping, rooting sts., tiny rosettes of deep green lvs., and many fls. of a rich crimson-red. This is considered by some to be identical with var. *pyrenaica* or very nearly so. Var. *pyrenaica*, Hort., is a robust very free-growing form, with large crimson fls. A form of this variety with very large rosy lilac fls. and a rather erect habit, said to come from the mountains of Wales, is cult. under the name of *S. pyrenaica superba*. G.C. II. 21:419. Var. *Rudolphiæna*, Kittel (*S. Rudolphiæna*, Hornsh.), a form with short branches, forming small, very dense tufts: upper lvs. and calyx-lobes glandular-ciliate: sts. short and more or less erect: fls. terminal and erect; petals obovate, 3-5-nerved. Austrian Alps. Var. *speciosa*, Farrer, has a stouter and bolder habit and foliage than other forms of the species and has very large pale rose fls. showing very little tendency toward the magenta. Var. *splendens*, Hort. (*S. spuria* var. *splendens*, Hort.), is a form with large fls. of a very bright purplish crimson or intense rose-purple, which are produced very freely in March. Wales.—This will grow well on a north exposure. It is also grown under the name of var. *pyrenaica splendens*.

98. *biflora*, All. (*S. rosea*, Lapeyr). Caudicles prostrate, branched, the branches ascending, pilose above, about 2 in. high: lvs. opposite, rather remote, thick, fleshy, green or purple, lower obovate-rotund, upper obovate-spatulate, apex rather obtuse, rarely acute,

1-pitted, sparsely pilose and also ciliate, dorsally subcarinate: infl. corymbosely paniculate, 2-9-fld.: fls. frequently in pairs, dark violet, deep purplish crimson or blackish blue; calyx broad-ovate, glandular-hirsute, lobes ovate obtuse, ciliate; petals lanceolate, 3-nerved, one-half longer than the calyx-lobes and narrower than them. April-July. Mountains of Eu.—Found wild in rocky debris watered by the melting snows. Seldom seen in cult.

99. *retusa*, Gouan. Caudicles prostrate, much branched, the branches densely cespitose, only about 1-2 in. high; fls.-sts. erect, 1-4-fld., glandular-hirsute above: lvs. rather stiff, green with a grayish cast, the lower and those of the sterile branches imbricate in 4 rows, spreading or recurved from their middle, oblong-lanceolate, apex flat-triangular and 3-5-pitted, 3-cornered-carinate; upper lvs. obovate ciliate at the obtuse, thickened, retuse apex, base hirsute: fls. large, rich ruby- to purple-red; calyx hirsute, the lobes oblong, obtuse; petals lanceolate, twice as long as the calyx-lobes. May-July. High Alps of S. Eu. Gt. 32:1110.—May be grown on a shady ledge in rich, but stony, well-drained soil. Not common in cult.

Section XV. PELTIPHYLLUM.

- A. Lobes of lvs. double dentate: fls. pinkish or white; petals ovate or elliptical, obtuse.....100. *peltata*
 AA. Lobes of lvs. coarsely mucronate-serrate: fls. greenish; petals spatulate, bidentate.....101. *tellimoides*

100. *peltata*, Torr. (*Peltiphyllum peltatum*, Engl.). UMBRELLA PLANT. Perennial, 1-3 ft. high, rhizome horizontal, fleshy, 2-3 in. thick: lvs. tufted, basal, long-petioled, the petioles often 1-3 ft. long and rough-glandular, blades large, peltate, almost centrally so, often 1 ft. across, orbicular, many-lobed, rather sharply and unequally toothed: infl. corymbose, borne on simple erect scapes which are longer haired than the petioles and appear before the lvs.: fls. numerous, pinkish or white, $\frac{1}{2}$ in. diam.; sepals ovate to oval, obtuse, glandular-ciliate; petals ovate to elliptical, obtuse. April. Margins of streams, Calif. and Ore. B.M. 6074. F.S. 23:2441. G.C. III. 27:139. Gn. 26, p. 545; 55, p. 6. Gng. 7:307. C.L.A. 17:412.—One of the largest of all saxifrages. Hardy in Mass., with slight protection, and a most desirable plant when bold effects are desired. Var. *gigantæa*, Hort., is offered in the trade.

101. *tellimoides*, Maxim. Up to 3 ft. or more high: st. robust, erect, leafy: lvs. radical, long-petioled, the petiole provided with short adnate stipules at its base, blade suborbiculate peltate, 5 in. or more across, 7-9-lobed, the lobes ovate and mucronate-acute, unequally and coarsely mucronate-serrate: infl. cymose, many-fld.: fls. short-pedicelled, greenish; calyx-lobes triangular-ovate; petals spatulate, bidentate at their apex, twice or more longer than the calyx-lobes. Japan. R.H. 1908, p. 251.—Hardy in England and resembles *S. peltata*.

Section XVI. HYBRIDS.

A. BETWEEN SPECIES OF SECTION I.

102. *cordifolia* × *purpurascens*, Hort. The following named forms are some of the results of reciprocal crosses of these 2 species. They are all robust, although varying much in stature and in color of fl. *Athlete*, Hort. (*Megasea Athlete*, Hort.), said to be a fine variety. *Brilliant*, Hort. (*S. cordifolia* var. *Brilliant*, Hort. *Megasea Brilliant*, Hort.). Lvs. large, richly tinted in autumn and winter: fls. purple; calyx and pedicels crimson. *compacta*, Hort. (*Megasea compacta*, Hort.). Fls. bright rose. *corrugata*, Hort. (*S. cordifolia* var. *corrugata*, Hort. *Megasea corrugata*, Hort.). Dwarf habit: lvs. large and rough: fls. pink. *Cræsus*, Hort. (*Megasea Cræsus*, Hort.). Very pretty with red fls.

Delia, Hort. (*Megásea Delia*, Hort.). Fls. crimson-purple. **Distinction**, Hort. (*Megásea Distinction*, Hort.). Dwarf crowded habit, with enormous head of pale pink or rosy purple fls. **Magnet**, Hort. (*Megásea Magnet*, Hort.). Fls. rose. **Progress**, Hort. (*Megásea Progress*, Hort.). A free-growing plant, with tall scapes of rosy purple, bell-shaped fls. which are $1\frac{1}{4}$ in. across. **Puck**, Hort. (*Megásea Puck*, Hort.). Large fls. **spléndens**, Hort. (*S. cordifolia* var. *spléndens*, Hort. *S. cordifolia* var. *híbrida spléndens*, Hort. *Megásea spléndens*, Hort. *M. híbrida spléndens*, Hort.). Fls. bright or rosy crimson.

AA. BETWEEN SPECIES OF SECTION II.

103. **Vetteriána**, Beauverd (*S. hederácea* $\times$ *S. Huetiána*). Lvs. intermediate between the two parents: fls. sulfur-yellow or whitish, the size of those of *S. Huetiána* and twice as large as those of *S. hederácea*; the petals more elongated than those of the last-mentioned species. June. Switzerland.—A spontaneous hybrid which appeared in the alpine garden of the Hortus Boissierianus.

AAA. BETWEEN SPECIES OF SECTIONS XI AND XII.

104. **Ándrewsii**, Harv. (*S. Gèum* $\times$ *S. Aizoon*. *S. Guthriána*, Hort., also spelled *Guthriána* and *Guthriána*. *S. acanthifolia*, Hort. *S. umbrósa* var. *acanthifolia*, Hort.). About 6 in. high: lvs. rather thick, in loose rosettes similar to *S. Aizoon*, but much longer and more or less lingulate: fls. white, thickly dotted with red for two-thirds the length of the petals. June. A spontaneous hybrid probably of garden origin. Gn.W. 25:598.—*S. Guthriána* is credited to the Pyrenees.

105. **Éngleri**, Huter (*S. Aizoon* $\times$ *S. cuneifolia*). Lvs. elongate, obovate-oval, the narrowed lower portion ciliate, margin indistinctly crenate and obscurely pitted: fl.-sts. about 4 in. high, glandular-hairy: infl. laxly 2-3-fld.: fls. very small. A garden hybrid.—Quite probably all of the material grown as *S. Éngleri* is not the same as another form, "with beautiful, long, silvered lvs. in handsome rosettes bearing upward of 20 handsome plumes of white fls. to a height, some of them, of more than 1 ft.," which is mentioned in English journals.

AAAA. BETWEEN SPECIES OF SECTION XII.

106. **Dr. Ramsey**, Hort. (*S. longifolia* $\times$ *S. cochleáris*). Resembles the latter parent more, but both the spoon-shaped lvs., which take on a brilliant red tint in the fall, and the infl. of white fls. are larger than in *S. cochleáris*. The fls. are sprinkled with pink dots. A garden hybrid.

107. **spléndens**, Hort. (*S. longifolia* $\times$ *S. Cotylèdon*). A showy plant about $1\frac{1}{2}$ ft. high, with silvery rosettes more like the former parent and the looser infl. of the latter: fls. white. A garden hybrid.

108. **Burnátii**, Sünderm. (*S. cochleáris* $\times$ *S. Aizoon*). Rather intermediate in character, but more nearly approaching the former parent in its lf.-rosettes and the infl. of large white fls. A natural hybrid found in the Maritime Alps.

109. **Gránfieldii**, Hort. Said to have been raised from *S. Aizoon* var. *rosularis*, by some said to be more probably raised from *S. Aizoon* var. *lutea*. The lvs. are ligulate, about 1 in. long and $\frac{1}{4}$ in. broad, encrusted and form a basal rosette: fls. pure white, unspotted and borne on stalks 15 in. high in spreading sprays. A garden hybrid of English origin. G. 36:673.

110. **Gaudínii**, Bruegg. (*S. Aizoon* $\times$ *S. Cotylèdon*). Also spelled *Gaudiniana*. Rosettes small and silver-gray: the fls. white. Supposed to be a spontaneous hybrid. Eu.

111. **Macnabiána**, Hort. (*S. Cotylèdon* $\times$ *S. Hòstii*. *S. Hòstii* var. *Macnabiána*, Hort.). The rosettes of

lvs. are intermediate in character, but the lvs. are much smaller than in *S. Cotylèdon* and the plant is seldom more than 1 ft. high, more or less branched above: fls. numerous, white, heavily speckled with pink to purple dots, the spots large. May, June. A garden hybrid. Gn.W. 20:868. J.H. III. 57:61.

AAAAA. BETWEEN SPECIES OF SECTION XIII.

112. **ambigua**, DC. (*S. média* $\times$ *S. aretioides*). About $2\frac{1}{2}$ in. high with reddish or purplish glandular fl.-sts.: lvs. linear, nearly obtuse and a little reflexed: fls. purple, red or coppery, with the petals a little longer than the calyx-lobes. Pyrenees. G.C. III. 54:183.—One of three native hybrids resulting from this cross. *S. ambigua* comes nearest to *S. média*, with red sepals and petals; *S. luteo-purpurea*, Lapeyr., is intermediate between the parents and has red sepals and yellow petals; while *S. Lapeyroussii*, Don, resembles *S. aretioides* more closely; its sepals are green and its petals yellow.

113. **aurantiaca**, Hort. (*S. média* $\times$ *S. aretioides*). More nearly resembling *S. aretioides* but the rosettes are larger: fls. yellow. Very similar to *S. luteo-purpurea*, Lapeyr.

114. **intermédia**, Hort. (*S. Grisebáchii* $\times$ *S. Stribnyii*. *S. Grisebáchii* var. *intermédia*, Hort.). Very similar in all respects to the former, but with a racemose infl. instead of a spicate one, the pedicels longer than those of *S. Grisebáchii*: fls. red. Probably a natural hybrid. G.C. III. 46:195.

115. **Bertolónii**, Sünderm. (*S. Friderici-Augusti* $\times$ *S. porophylla*). Nearer the former parent in habit, about 3 in. high, the rosettes of lvs. $1\frac{1}{2}$ in. diam.; lvs. long, narrow, and pointed, with the chalk-pits very evident: infl. a nodding raceme borne on a red st. with red leafy bracts which are tipped with green: fls. red, on short pedicels. A garden hybrid.—Does well in a crevice or on a ledge, but requires lime.

116. **Kéllereri**, Sünderm. (*S. Friderici-Augusti* $\times$ probably a form of *S. Burseriána*). Inclined in habit to the former, with well-developed rosettes which are nearly 2 in. diam., but the lvs. are longer and narrower and are acutely pointed and pitted with white dots: fl.-sts. 5 in. high, glandular-hairy and terminated by a cluster of erect pink-tinted fls.; the shade deeper toward the base, fls. cylindrical in form with the petals never reflexed. Feb., March. A garden hybrid.

117. **Eudoxiána**, Kellerer (*S. Ferdinándi-Còburgi* $\times$ *S. sancta*). An intermediate in character, but vigorous like *S. sancta*. The lvs. have the silvery appearance of the former parent and the length and pointedness of the latter: sts. tinged red and bearing a head of 2-3 deep orange-yellow fls. which are rather small. A garden hybrid raised at Sofia, Bulgaria.

118. **apiculàta**, Engl. (*S. Rocheliána* $\times$ *S. sancta*. *S. Friderici-Augusti*, Hort., not Bias. *S. luteo-purpurea*, Hort., not Lapeyr). Cespitose, forming a large dark green mat, with subligneous, very densely lvd. caudicles fl.-sts. 2-3 $\frac{1}{2}$ in. high, glandular-pilose: basal lvs. linear-oblong, acutely cuspidate, slightly carinate, thick, with pitted margins; cauline lvs. subspatulate: infl. 5-9-fld., the branches 1-2-fld.: fls. yellow; calyx with the tube turbinate and densely glandular-pilose; lobes ovate-oblong, apiculate and glandulose-ciliate; petals obovate, spreading, a little longer than the calyx-lobes. Dec.-March. Said to be from the Pyrenees. B.M. 8048. G.C. III. 15:557; 39:250. G.M. 49:208. Gn. 69, p. 210; 76, p. 147. Gn.W. 20:67. G.W. 11, p. 4. J.H. III. 44:186. Var. *álba*, Hort. Habit free, the fl.-sts. 3 in. high, the fls. pure white or pale cream-colored and borne profusely. G. 34:233. Gn. 73, p. 201. Var. *Mályi*, Hort. (*S. Mályi*, Hort., not Schott, also spelled *Mayli* and *Molyi*. *S. luteo-purpurea* var. *Mályi*, Hort.), has deeper-colored fls. which are better shaped and

later opening than the type. Var. *pállida*, Hort., a form said to have pale yellow fls., is offered in the trade.

119. *púngens*, Sünderm. (*S. Rocheliana* × *S. juniperifolia*). In general appearance it is similar to the latter parent, with rather smaller rosettes of dark green, sharp-pointed lvs., but with the more compact habit of *S. Rocheliana*. Its fl.-sts. are about 1–2 in. high, glandular-hairy and tinged red-brown, bearing several deep golden yellow fls. which are larger and paler than those of *S. juniperifolia*. A garden hybrid.

120. *Bòrisii*, Kellerer (*S. marginata* × *S. Ferdinándi-Còburgi*). It more closely resembles the latter parent. About 2–3 in. high with large rosettes of silvery lvs.; bracteate, glandular sts. each bearing 4 or 5 large yellow fls. which are paler than *S. Ferdinándi-Còburgi*. A garden hybrid raised in Sofia, Bulgaria.—*S. Kyrillii* is another product of the same cross.

121. *Kyrillii*, Kellerer (*S. marginata* × *S. Ferdinándi-Còburgi*). Another product of the same cross as *S. Borisii* but more closely resembling the former parent. The lvs. show the chalk-pits more distinctly; the green, glandular sts. are about 3 in. high and bear pale yellow fls. which are lighter and usually larger than those of *S. marginata*. March. A garden hybrid, raised at Sofia, Bulgaria.

122. *Súndermannii*, Hort. (*S. marginata* × *S. Burseriana*). A smaller plant than *S. Obristii* (a result of the reciprocal cross) and resembling the latter parent more closely. About 2–3 in. high, habit tufted and free-growing, the rosettes larger than in *S. Obristii*, $\frac{5}{8}$ in. diam.: lvs. $\frac{1}{4}$ in. long, broadest at the base and tapering to a point as in *S. Burseriana*, upper surface channeled or concave and covered with a chalky deposit on the margins and apex: infl. 1- or 2-fl., borne on green fl.-sts. which are obtuse, bracted, and covered with glandular white hairs: fls. white, $\frac{3}{4}$ in. across; sepals obtuse, tinged red-brown and glandular; petals with crisped margins as in some forms of *S. Burseriana* and double the length of the sepals. A garden hybrid. G.C. III. 49:228.—Very free-flowering.

123. *Pétraschii*, Sünderm. (*S. tombeanensis* × *S. Rocheliana*). Of neat habit and very free-flowering. The plant has compact cushions of glaucous lvs. in rosettes: sts. about 2 in. high, glandular and red-tinged, bearing heads of 3–5 large white fls. which are 1 in. across. March, April. A garden hybrid. G.C. III. 49:172. G. 33:231. Gn. 75, p. 190. G.M. 54:201.—Does best on a soil which has been liberally mixed with pieces of sandstone.

124. *kestoniensis*, Hort. Supposed to be a seedling of *S. Burseriana*, though by some said to resemble *S. scardica* var. *obtus*a more closely. It has very white fls. which come very early and are starry. The fl.-sts. are bright red and about 3 in. high. Jan.–March. A garden hybrid.

125. *Bòydii*, Dewar (*S. Burseriana* × *S. aretioides*. *S. Burseriana* var. *Bòydii*, Hort.). Plant tufted, gray and very slow-growing, fairly intermediate: lvs. more nearly resembling *S. Burseriana*, but instead of tapering to an acute point they are linear with an abrupt point: infl. 1–3, rarely 4–5-fl.: fls. almost as large as those of *S. Burseriana*, but yellow as in *S. aretioides*. March. A garden hybrid. G.C. III. 39:250. G. 32:333. G.M. 53:317.

Var. *álba*, Hort. (*S. Burseriana* var. *Bòydii*, Hort.). A plant which very little resembles *S. Boydii* and by some is thought to be a hybrid (*S. Rocheliana* var. *coriophylla* × *S. Burseriana*). Lvs. subulate, arranged in small rosettes which form dense cushions: fls. white, borne on scapes about 2 in. high, bearing a cyme of 3–4 fls. Gn. 71, p. 178; 72, p. 177. It resembles *S. Burseriana* in many respects but differs in having larger lvs. and more fls. to a scape. Var. *késtoni*, Hort., is offered in the trade,—possibly the same as *S. kestoniensis*.

126. *Faldonside*, Boyd (*S. Burseriana* × *S. aretioides*). Lvs. silvery: st. suffused with pink: fls. lemon-yellow, borne in 2's or 3's, $\frac{3}{4}$ in. diam., of beautiful form with full overlapping petals which are crimped at the edges; the small orange-colored glandular disk in the center of the fl. adds to its attractiveness. Feb., March. A garden hybrid.—Free-flowering. The same cross as *S. Boydii* but freer growing and with larger fls. of a better form.

127. *Salomònnii*, Sünderm. (*S. Burseriana* × *S. Rocheliana*. *S. salmònica*, Hort.). The habit is more that of the former but the infl. and stronger growth that of the latter parent: rosettes usually $\frac{1}{2}$ in. diam.; lvs. awl-shaped, 3-cornered with cartilaginous margins and decidedly glaucous: fl.-sts. $1\frac{1}{2}$ –2 in. high, tinged red, pubescent and covered with lvs.; fl.-buds suffused with pink, but fls. white, more the substance of *S. Rocheliana* and borne 3 or 4 to a st., about $\frac{3}{4}$ in. across. Feb., March. A garden hybrid. Gn.W. 22:291.

128. *Obristii*, Sünderm. (*S. Burseriana* × *S. marginata*). A robust plant, about 3–4 in. high, with rosettes about $\frac{3}{4}$ in. diam.: sts. glandular and tinged red-brown: lvs. strap-shaped, acute, with 4 or 5 chalk-pits on their margins: fls. 2–4 to a st., large, almost 1 in. across, ivory-white; petals broad, rounded and overlapped as in *S. marginata*. March. A garden hybrid. G.C. III. 49:229.—It is very like an enlarged *S. Burseriana* in general appearance though the foliage is intermediate and the fls. resemble *S. marginata*. Another distinct form resulting from this cross is *S. Sundermannii*.

129. *Elizabethæ*, Sünderm. (*S. Burseriana* × *S. sáncta*. *S. Cherrytrees*, Hort.). Very free-growing, forming cushion-like tufts: lvs. deep green, in small rosettes which are closely packed together: fl.-sts. 2 in. high, tinged red, glandular; the bracts tipped with green: fls. yellow (variously stated as sulfur, primrose, and canary), quite large and in heads of 3–5. March, April. A garden hybrid. G.L. 18:116; 25:153.

130. *Írvingii*, Hort. (*S. Burseriana* var. *macránt*ha × *S. Friderici-Augústi*. *S. Burseriana* var. *élegans*, Hort. *S. Burseriana* var. *rósea*, Hort.). This partakes more of the character of the former, with similar tufts of foliage and single fls. The latter parent shows in the color of the fls. which are blush-pink, deeper at the center. The fl.-sts. are only 1 in. or so high and the plant is very free-blooming. March. A spontaneous hybrid at Kew. G.C. III. 57:158. G. 37:187. Gn. 76, p. 193; 79, p. 152. G.M. 58:149.—*S. kewensis* is another product of the same cross but more allied to *S. Friderici-Augusti*.

131. *kewensis*, Hort. (*S. Burseriana* var. *macránt*ha × *S. Friderici-Augústi*). About 2–3 in. high with the lvs. of the latter parent but the cushioned habit of the former: sts. pale glandular-hairy; bracts red tipped with green: fls. intermediate in shape; sepals deep red and glandular, while the petals are rose, much deeper colored toward their base. March. A garden hybrid. G.C. III. 51:247.

132. *bursiculàta*, Jenkins (*S. Burseriana* var. *màjor* × *S. apiculàta*). Plant about 3 in. high, with silver-gray rosettes: lvs. acutely pointed, glaucous and similar to the former parent, while the horizontal spread of the rosettes and their size show the influence of *S. apiculata*: fl.-sts. 3–4-fl.: fls. large and white. March. A garden hybrid. G.C. III. 49:158. G. 33:183. Gn. 75, p. 155. G.M. 54:188. J.H. III. 62:357.

133. *Paulinæ*, Sünderm. (*S. Burseriana* var. *mìnor* × *S. Ferdinándi-Còburgi*). Habit compact, nearer like that of the latter parent, about 2 in. high, with larger rosettes of glaucous foliage: sts. tinged with red and fls. pale yellow, about $\frac{3}{4}$ in. diam. March. A garden hybrid.—Somewhat resembles *S. Elizabethæ*, but the foliage is more glaucous and the rosettes are smaller. Var. *compàcta*, Hort., is said to have compact cushions

of dark green foliage and stout sprays of clear yellow fls. resembling *S. Boydii*.

134. *Haagei*, Sünderm. (*S. sancta* × *S. Ferdinandi-Cöburgi*). This more nearly resembles the latter parent. Its habit is very compact, its foliage is similar and glaucous: fl.-sts. 2-3 in. high, bracted, tinged red-brown and glandular-hairy: fls. golden yellow, 4-5 to a st., clustered in heads. March, April. A garden hybrid. Gn. 78, p. 170.

135. *Godseffiana*, Hort., also known as *S. Godseffi* and *S. L. S. Godseff* (*S. sancta* × *S. Elizabethæ*). Habit of growth intermediate, foliage spiny and in close tufts: fl.-sts. 3-4 in. high, reddish and having reddish green-tipped lvs.: fls. an improvement on *S. Elizabethæ*, being deeper yellow and having better form. A garden hybrid.

S. atrovirens, Hort., is offered in the trade as a form growing 6 in. high, with white fls. Probably belongs in Section Dactyloides.—*S. Bäckeri*, Hort., is one of the smaller mossy saxifrages with vivid green foliage, a plant of compact habit with rich carmine or rose fls. Probably belongs in Section Dactyloides.—*S. Böykei*, Hort., is offered in the trade.—*S. capillaris*, Hort., is offered in the trade as a white-fl. species.—*S. carnifolia*, Hort., is offered in the trade and said to have white fls.—*S. caryophylla*, Hort., is offered in the trade as one of the easiest to grow, fls. white. Perhaps a misspelling of *coriophylla*, which is a variety of *S. Rocheliana*.—*S. circutata*, Hort., is said to have silvery braided foliage and pretty little panicles of white fls. borne on sts. 4 in. high. It belongs to Section Euaizonia.—*S. cristata hybrida*, Hort., is offered in the trade as a form growing 6 in. high, with white fls. Probably a form of *S. Aizoon* near var. *paradoxa*.—*S. elatior*, Mert. & Koch= *S. Hostii*.—*S. elatior*, of German authors= *S. altissima*.—*S. elatior*, Wimm.= *S. Aizoon* var. *major*.—*S. Ganolini*, Hort., is offered in the trade as growing 6 in. high with white fls.—*S. Håwörthii*, Hort., forms cushions of rather pale green, about 6 in. high, the growth being packed and somewhat rounded at the top: fls. pure white and numerous. Probably belongs in Section Dactyloides.—*S. Héctori*, Hort., is offered in the trade.—*S. hybrida*, Hort., not others= *S. decipiens*.—*S. hybrida*, Haw.= *S. hypnoides*.—*S. incurvifolia*, Hort., not Don, is listed as belonging to the encrusted section and as having white fls.—*S. incurvifolia*, Don, is a variety of *S. cespitosa*.—*S. lævis*, Hort. (?) of Bieb. and of Oettingen. The plant in cult. under this name belongs to Section Trachyphyllum and has a spreading habit like *S. aizoides* with loose rosettes of narrow elliptic-oval lvs.: fl.-sts. about 2 in. high, tinged crimson below and bearing each 4-6, not large, rich yellow fls. Caucasus. Requires a moist situation.—*S. lævis*, Bieb., also from Caucasus, is placed in Section Kabchia by Engler, but by several other authors is said to be close to *S. Aizoon* or *S. aizoides* and may be the same as the plant in cult.; if not the one now grown as *S. lævis* must receive a new name.—*S. lævis*, Oettingen, seems to be the same as that of Bieb. as far as the description is concerned; the plants have not been seen.—*S. lævis*, Hort., is offered in the trade as a very compact form, 6 in. high, with white fls. Probably belongs in Section Dactyloides.—*S. Lindesiana*, Hort., also spelled *Lindisiana*, is offered in the trade as a mossy species with white fls. Perhaps belongs in Section Dactyloides.—*S. lingueformis*, Hort., is offered in the trade.—*S. palmata*, Hort., is uncertain and seems to be sometimes *S. decipiens*, sometime *S. geranioides*. Var. *foliis variegatis* is a variety of one of these species with variegated foliage.—*S. paradoxa*, Hort., is described in a trade-list as a beautiful member of the Aizoon group with long and "braided" foliage. Presumably a natural hybrid between *S. crustata* and *S. Hostii*. Considered by some as a variety of *S. Aizoon*, which see.—*S. paradoxa*, Kit.= *S. moschata* var. *pygmaea*.—*S. pectinata*, Pursh= *Luetkea pectinata*, Kuntze.—*S. pedatifida*, Hort., is offered in the trade as a white-fl. species.—*S. Pseudo-Fosteri*, Hort., is offered in the trade as a hybrid of the encrusted section. Var. *sancta*, Hort., is offered in the trade as an early yellow-fl. form.—*S. pyrolifolia*, Don= *Leptarrhena pyrolifolia*, R. Br.—*S. Ringiana*, Hort., is offered in the trade as a dwarf plant of spreading habit, growing 4 in. high and having white fls. Probably belongs in Section Dactyloides.—*S. rupëstris*, Lapeyre.= *S. ascendens*.—*S. rupëstris*, Salisb.= *S. hypnoides*. Which of these the material offered in the trade as a very compact plant growing 6 in. high, with white fls. cannot be determined with certainty, though probably the second as it is said to belong to the mossy section.—*S. Schroederi*, Hort., is offered in the trade as allied to *S. ceratophylla* which is a variety of *S. trifurcata*, a species of Section Dactyloides.—*S. sexmifida*, Hort., is offered in the trade.—*S. Stibthorpii*, Boiss. Fig. 35. Of the Cymbalaria group: perennial, cespitose, with reniform, long-stalked obtuse-lobed lvs. and small yellowish fls.: petals ovate-elliptic. A good rock-plant, but seems not to be in the trade.—*S. Stansfieldi*, Wm. Robinson, is said to have a close-growing habit, dark green foliage and white fls. borne on sts. 4 in. high. Perhaps it belongs in Section Dactyloides.—*S. stellata*, Hort., not Pav., is offered in the trade as a white-fl. mossy plant, 1 ft. high. This is unquestionably not the stellata of Pavon which is the Peruvian representative of *S. cespitosa* and grows scarcely 1 in. high.—*S. stenoglossa*, Tausch. Lvs. of the rosette rather erect, cuneate or cuneate-linear, acute, serratures narrow, the lower ones spreading, the uppermost contiguous, with the terminal tooth slightly protruding. A plant is offered under this name, but whether the same as the indeterminate Tausch species it is impossible to say. The above given description is a translation of the original of Tausch.—*S. Tantiana*, Hort., is offered in the trade.—*S. triophylla*, Hort., is offered in the trade as a white-fl. species. Var.

persifolia, Hort., is also offered.—*S. tenuifolia*, Hort., is offered in the trade as growing 6 in. high, with white fls. Probably belongs in Section Dactyloides.—*S. Van Houtei*, Hort., is offered in the trade. It belongs to Section Bergenia and has light pink fls.—*S. venetica*, Hort., is offered in the trade as a species with minute tufts and primrose-yellow fls. belonging in the encrusted section.—*S. Webbiana*, Hort., is offered in the trade. Possibly belongs in Section Dactyloides.

F. TRACY HUBBARD.

SCABIOSA (Latin, *itch*, referring to medicinal use). *Dipsacaceæ*. SCABIOUS. MOURNING BRIDE. Annual or perennial herbs, their base more or less woody, comprising some of the showy and commonly cultivated garden flowers.

Leaves entire, dentate-lobate or dissected: heads terminal, depressed subglobose or ovoid-conical, pedunculate or rarely sessile in a dichotomous infl.; bracts of the involucre 1-2-rowed, herbaceous: fls. blue, rose, yellowish, or white; calyx bristly; corolla-limb 4-5-cleft, subequal or frequently oblique or 2-lipped; stamens 4, very rarely 2: achene adnate to the involucre at the base or up to the middle.—About 70 species, Eu., Asia, and Afr., rare in the tropics.

In any moderately good garden soil a succession of flowers is produced from June until frost. The flowers are very serviceable for cutting purposes. Propagated by seed or division. Many of the perennial species act like biennials in cultivation, and often flower the first year from seed. *S. atropurpurea* is a common garden annual, of easy cultivation from seed.

KEY TO THE SPECIES.

- A. Radical lvs. dentate or lobed.
 - B. Fls. yellow (horticultural variations of Nos. 5 and 7 are yellowish).... 9. *ochroleuca*
- BB. Fls. dark purple, rose, crimson, blue, or white (forms of Nos. 5 and 7 are yellowish).
 - C. Calyx-limb sessile or nearly so.
 - D. Surfaces of lf. pilose-pubescent with appressed white hairs... 5. *ucranica*
 - DD. Surfaces of lf. pubescent, but not with appressed white hairs... 10. *Columbaria*
- CC. Calyx-limb pedicellate.
 - D. Plant 6-18 in. high..... 3. *stellata*
 - DD. Plant 2 ft. high..... 7. *atropurpurea*
- AA. Radical lvs. entire.
 - B. Plants annual.
 - C. Lvs. oblong-spatulate..... 6. *Reuteriana*
 - CC. Lvs. ovate-oblong..... 4. *brachiata*
 - BB. Plants perennial.
 - C. Prevailing shape of blade linear, but occasionally broader..... 2. *graminifolia*
 - CC. Prevailing shape of blade lanceolate, but occasionally narrower.. 1. *caucasica*

1. *caucasica*, Bieb. A hardy perennial 18 in. high: lvs. glaucous or whitish, the lower lanceolate-linear, acute, the upper cut and divided; heads flattish: fls. light blue. June-Oct. Caucasus Mts. Gn. 35, p. 121. G. 4:423; 25:443. Gn. W. 23:481; 26:171. Var. *alba*, Hort., has white fls. G. 29:71. G. M. 38:839. There is also a form of this, var. *alba perfecta*, Hort., which is offered in the trade—possibly the same as var. *perfecta*. Var. *magnifica*, Hort., is a large-fl. form with deep lavender-blue fls. Gn. 77, p. 445; 78:58. G. M. 56:674. Var. *pallida*, Hort., has silver-gray foliage. Var. *perfecta*, Hort., has large fringed fls. G. W. 3, p. 587..

2. *graminifolia*, Linn. A perennial herb, somewhat woody at the base, about 1 ft. high: lvs. linear, silvery: fls. pale blue. June-Oct. Eu. B. R. 835. G. 36:443

3. *stellata*, Linn. An annual plant, hairy, simple or somewhat branched, 6–18 in. high: lvs. cut or somewhat lyrate, the terminal lobe large, obovate, dentate, the upper ones often pinnately parted: fls. blue, in long-peduncled heads; corolla 5-cleft, the lobes radiate. June and later. S. Eu.

4. *brachiata*, Sibth. & Smith. An annual species about 1 ft. high: lower lvs. ovate-oblong, the upper pinnately cut, lyrate; the lower lobes decurrent, the terminal large, obovate, oblong: fls. light blue. June and later. Eu., Asia.—Recent authors have kept this distinct as the type of the genus *Callistema* where it becomes *C. brachiatum*, Boiss.

5. *ucránica*, Linn. (*S. Wulfenii*, Roem. & Schult.). Biennial or perennial: sts. erect, branched: lvs. pilose-pubescent with appressed white hairs; the lower pinnately parted, segms. oblong or oblong-linear, entire or dentate; the upper often undivided: calyx-limb short-stipitate; corolla white or yellowish white, rarely rose or blue, lobes nearly entire or crenate: fruiting head spherical. Eu., Asia Minor, and Persia.

6. *Reuteriana*, Boiss. Annual: st. erect, branched: lower lvs. oblong-spatulate, entire; the other lvs. lyrate, lateral segms. on each side 1–2, short, lanceolate, terminal segm. much larger: involucre setose at base: calyx-limb short-stipitate; corolla pale violet, lobes denticulate: fruiting head ovate. Asia Minor.

7. *atropurpurea*, Linn. (*S. major*, Hort. *S. maritima*, Linn. *S. calyptocarpa*, St. Amans). SWEET SCABIOUS. Fig. 3564. An annual branching plant about 2 ft. high: radical lvs. lanceolate-ovate, lyrate, coarsely dentate; st. lvs. pinnately parted, the lobes oblong, dentate or cut: fls. dark purple, rose, or white, in long-peduncled

also known horticulturally as *grandiflora minor*, is a smaller-growing group of plants, very much branched, of which the following forms are named in the trade: *minor aurea flore-pleno*, also known as *S. minor aurea flore-pleno*, which has light yellow double fls.; *nana foliis-aureis* with yellow foliage, and *nana plena*. Var. *pumila*, Hort., also known horticulturally as *grandiflora pumila*, is a dwarf group occurring in various colors; there is also a double form horticulturally known as *pumila flore-pleno*. This is the group listed in the trade as Tom Thumb.—The forms of *S. atropurpurea* are among the most popular of flower-garden annuals. Seeds sown in the open ground in spring should give bloom in early summer and continue till frost. The composite-like heads are produced on long sts., good for cutting.

8. *japonica*, Miq. Perennial, tufted, about 2 ft. high, dichotomously branched: lvs. pinnatisect, lobes narrow: fl.-heads terminal or axillary, very long-peduncled, violet-blue, about 2 in. across, involucre bracts in 2 rows, very unequal, shorter than the fls. Sept. to frost. Japan.—Closely allied to *S. atropurpurea*.

9. *ochroleuca*, Linn. (*S. Columbària* var. *ochroleuca*, Hort. *S. alata*, Hort.). A hardy perennial herb about 18 in. high: st. branching and somewhat hairy: lvs. whitish-pubescent, the radical crenate or lyrate pinnatifid, tapering to a petiole, pubescent on both sides, those of the st. 1–2-pinnately divided or cleft into oblong or linear lobes: peduncles long, slender: lvs. of the involucre shorter than the fls. June to autumn. Eu. and Asia. Var. *Webbiana*, Hort. (*S. Webbiana*, D. Don). Height 6–10 in.: lower lvs. canescent-villous, the upper glabrous. Resembles the type but is smaller in all its parts. B.R. 717.

10. *Columbària*, Linn. A hardy perennial quite variable in character, 2 ft. high: st. branching, glabrous or nearly so: radical lvs. ovate-obtuse, crenate, membranous, pubescent on both sides; st. lvs. glabrous, pinnately parted, the segms. linear, entire or slightly incised: fls. blue, in ovate-globular heads on long pubescent peduncles. June–Sept. Eu., Asia, Afr. Var. *alba*, Hort., is a white-fl. form.

S. alpina, Linn.—*Cephalaria alpina*, Schrad.—*S. elata*, Hornem.—*Cephalaria tatarica*, Schrad.—*S. lutea*, Hort., is a perennial growing 5–7 ft. high: fls. yellow, not known botanically. G. 25:442. Var. *gigantea*, Hort., is also offered in the trade.—*S. tatarica*, Linn.—*Cephalaria tatarica*, Schrad. R.B. 33:353.

F. TRACY HUBBARD.†

SCABIOUS. For common scabious, see *Scabiosa*. For Shepherd's or Sheep scabious, see *Jasione perennis*.

3564. *Scabiosa atropurpurea*.—The mourning bride or pin-cushion flower. (×½)

heads, becoming ovate or oblong in fr. July–Oct. S. Eu. Gn. 21, p. 118. B.M. 247. F.S. 12:1203.—Very variable and in common cult. *S. varia*, Hort., not Gilib., is probably a name applied to mixed varieties of *S. atropurpurea*. Var. *candidissima*, Hort., is a white-fl. form; also occurs double under the horticultural names of *candidissima flore-pleno* and *candidissima plena*. Var. *coccinea*, Hort., is a scarlet-fl. form. Var. *compacta*, Hort., only a compact form, probably referable to var. *grandiflora*. Var. *flore-pleno*, Hort., see var. *grandiflora*. Var. *grandiflora*, Hort. (*S. grandiflora*, Hort. *S. atropurpurea* var. *maxima*, Hort. *S. atropurpurea* var. *flore-pleno*, Hort.), is really a large-fl. strain occurring in several variant forms based on habit, fl.-color, and the like. One form is known horticulturally as *grandiflora compacta*, also occurring double, and a second as *maxima plena*. By some authorities this variety includes all the others; it is the common garden strain. Var. *major*, Hort., also known horticulturally as *grandiflora major*, is a tall-growing form of which the following variations are named in the trade: *major aurantiaca*, *major sulphurica*, and *major compacta atropurpurea*. Var. *maxima*, Hort., see var. *grandiflora*. Var. *minor*, Hort., see var. *nana*. Var. *nana*, Hort. (*S. atropurpurea* var. *minor*, Hort. *S. minor*, Hort.),

SCÆVOLA (Latin, a diminutive of *scæva*, the left-handed, probably alluding to the form of the corolla). Goodeniaceæ. Herbs, subshrubs, or shrubs suitable for greenhouse culture: lvs. alternate: fls. solitary between 2 bracteoles, sessile or pedunculate, axillary or the peduncles dichotomously branched with a fl. in each fork; calyx-tube adnate, limb usually very short; corolla oblique, the tube slit open to the base, lobes nearly equal; ovary wholly inferior or rarely the summit free, 2-celled with 1 erect ovule in each cell, or 1-celled with 1 or 2 erect ovules: fr. indehiscent, more or less succulent.—About 83 species, mostly Australian, but also the Pacific islands, Asia, and one each in Afr. and the W. Indies. A few of the species which have been cult. are: *S. attenuata*, R. Br., with broadly lanceolate lvs. and blue fls. in terminal leafy spikes. Austral. B.M. 4196. *S. cuneiformis*, Labill., with obovate lower and oblong-cuneate upper lvs. and blue fls. in a long interrupted spike. Austral. *S. suaveolens*, R. Br., a prostrate, or decumbent hardy perennial or subshrub with petiolate lvs. obovate to oblong-spatulate, and blue fls. in interrupted terminal hirsute spikes. Aug. Austral. For a recent treatment of this genus, see Krause in Engler's *Pflanzenreich*, hft. 54 (IV. 277 and 277a), 1912.

SCÁNDIX (Greek, *to sting*, in reference to the roughness of the fr.). *Umbelliferae*. Glabrous or pubescent annual herbs, one of them grown for foliage and bloom: lvs. pinnately decomposed, the segms. small and narrow: umbels composite, few-rayed, or now and then simple (1-rayed); involucre none or 1-bracted; fls. white, polygamous; calyx-teeth minute or wanting;

3565. *Scandix pecten-veneris*. ($\times \frac{1}{2}$)

petals often unequal, oblong, cuneate or obovate: fr. oblong-linear, laterally compressed, long-beaked, primary ridges prominent, broad obtuse or filiform.—About 12 species natives of temperate or subtropical regions of the northern hemisphere.

Pecten-Veneris, Linn. Fig. 3565. A hardy garden annual 6–12 in. high, with finely cut lvs. and small white fls. in simple umbels. Eu.—Little grown.

S. cerefolium, Linn. See Chervil.

SCAPHOSÈPALUM (Greek, *boat* and *sepal*, alluding to the form of the lower sepal). *Orchidaceae*. A genus separated from *Masdevallia* on the character of the lateral sepals, which are united into a boat-shaped organ. In habit the plants resemble *masdevallias*, except that the parts of the rhizome are longer, thus making the tufts less compact, and the racemes assume climbing habits, becoming very long and bearing fls. for months in succession. The dorsal sepal is free or nearly so; labellum and sepal small.—The genus contains about 10 or more species.

Grow in a coolhouse well protected from the sun. Keep the summer temperature as low as possible. Give plenty of water when growing. When at rest, water sparingly but do not allow the plants to become entirely dry. Use as small a pan as possible. The culture is like that for *masdevallia*. (Wm. Mathews.)

gibberdsum, Rolfe (*Masdevallia gibberdosa*, Reichb. f.). Lvs. 3–5 in. long, oblong-obovate or lanceolate, obtuse: peduncle 6–10 in. long, warty, bearing a loose raceme of 4–8 fls.: dorsal sepal boat-shaped, with a long tail, dull red, with strong, greenish ribs; lateral sepals partly connate in a concave lamina, then spreading horizontally, yellow, spotted with red and ending in yellowish tails. Colombia. B.M. 6990.

punctatum, Rolfe (*Masdevallia punctata*, Rolfe). Densely tufted: lvs. elliptic-lanceolate, subacute, 3–5

in. long: peduncles pendulous: fls. small, dull yellowish, thickly speckled with crimson; dorsal sepal broadly ovate, concave, strongly 5-ribbed, ending in a stiff incurved tail; lateral sepals spreading horizontally, falcately incurved, with a filiform process near the tip. Colombia. B.M. 7165.

HEINRICH HASSELBRING.

SCAPHYGLÓTTIS (Greek, *boat* and *tongue*, referring to the hollowed labellum). *Orchidaceae*. Branched epiphytic orchids grown in the warmhouse: new branches borne annually at the apex of the old branch, solitary or paired, sheathed at the base, 2-lvd. at apex, finally fleshy thickened, forming pseudobulbs which are linear or narrowly fusiform: lvs. narrow, sometimes linear, coriaceous: fls. in pairs or few in fascicles between the lvs. at the base of the innovation, small; sepals erect and rather spreading, lateral broader than the dorsal; petals similar to the sepals; labellum articulate or continuous with the foot of the column, not divided or obscurely lobed; column rather long, 2-auricled at the apex; pollinia 4.—About 15 species, Mex. to Brazil.

alba, Rolfe. Sts. fascicled, narrowly spindle-shaped, $1\frac{3}{4}$ –2 in. long, 2-lvd.: lvs. linear, $1\frac{3}{4}$ –2½ in. long, minutely bilobed at apex: fls. small, white, in fascicles of 3 or 4; sepals oblong, rather connivent; petals somewhat narrower; lip cuneate-oblong, nearly entire. Hab. (?)

S. Cogniauxiana, Wildem. A small species with narrow lvs. 2–4 in. long: fls. greenish yellow; sepals acute, petals subacute. Brazil.—*S. stellata*, Lodd., differs from *S. violacea* in having larger fls., with more spreading segms. and lateral lobes of the lip as large as the middle one. Guiana.—*S. violacea*, Lindl. Sts. terete, striated, articulated: lvs. 2–3 in. long, linear or linear-lanceolate: fls. violet, minute; lateral sepals twice as broad as the dorsal; lip white, fleshy, channeled. Guiana. B.M. 4071. B.R. 1901.

F. TRACY HUBBARD.

SCHÆNÓSTOMA: *Chænostoma*.

SCHAUËRIA (after J. C. Schauer, professor at Greifswald, 1813–1848). *Acanthaceae*. Erect half-shrubby herbs, of greenhouse cult., with entire lvs.: fls. yellow or red, in a terminal thyrses or spike; calyx 5-parted, segms. linear or setaceous; corolla-tube long, gradually broadened upward; limb 2-lipped, the upper lip interior narrow, entire or emarginate, erect, lower lip cut into 3 subequal, recurved segms.; stamens 2 each, with 2 parallel anthers, about as long as the upper lip; aborted stamens wanting; style filiform; ovary seated on a disk, 2-loculed, with 2 seeds in each locule.—About 8 species from Brazil. Closely related to *Jacobinia*, from which it differs by the equal parallel anther-cells. It is distinguished from *Anisacanthus* by its setaceous calyxlobes, and from *Fittonia* by its habit.

flavicomma, N. E. Br. (*Justicia flavicomma*, Lindl. *Justicia flava*, Hort., not Kurz.). Fig. 3566. Half-shrubby plant, with erect, branched sts. up to 4 ft. high: lvs. opposite, petiolate, ovate to ovate-lanceolate, shining green, undulate: fls. light yellow, $1\frac{1}{2}$ in. long, borne in erect, feathery panicles; calyx-

3566. *Schaueria flavicomma*, often known to the trade under the name of *Justicia flava*. ($\times \frac{1}{2}$)

lobes long, subulate, glandular-hairy, persistent after the corolla has fallen. Autumn. Brazil. B.M. 2816 (as *Justicia calycotricha*). B.R. 1027. L.B.C. 20:1921 (as *Justicia callitricha*). J.H. III. 61:277.—This plant has been confused with *S. calycotricha*, Nees, and has long been cult. under that name. *S. calycotricha*, Nees, has a smooth calyx and broader ovate lvs. which are very obtuse or subcordate at the base.

HEINRICH HASSELBRING.

SCHEELEA (after Scheele, distinguished German chemist). *Palmaceæ*. Pinnate palms from Trop. S. Amer. They are spineless, tall or dwarf; lf.-segms. arranged in regular series or grouped, linear, in young plants unequally and obtusely 2-cut at the apex; fls. yellowish, dioecious or monœcious, the males very numerous in the upper part of the branches, the females few or solitary in the lower part and sometimes peduncled; petals of the males long-club-shaped or cylindrical; stamens 6, shorter than the petals; fr. 1-3-seeded.—About 10 species. Almost unknown in Amer. Cult. in hot moist house. Prop. by rarely obtainable imported seeds. Considered by some the same as *Cocos butyracea*. The following species has never been described as a Scheelea and it is only by inference on Karsten's part that it can be placed there. *S. butyracea*, Karst. This species was once cult. in S. Calif. Franceschi remarks that it comes from Venezuela and is a magnificent palm with the habit of attalea. H. A. Siebrecht states that it is rare in cult. and that it is more interesting than beautiful. On account of its large st.-base or crown, it requires so large a pot or tub for the size of the plant that it does not make a very ornamental subject.

N. TAYLOR.†

SCHEERIA (Frederick Scheer presented the original species to the Royal Botanic Gardens at Kew, he having received material in 1850, through J. Potts, from Chihuahua, Mex.). *Gesneriaceæ*. A name proposed for 4 Mexican and Trop. American herbs which are now referred to *Achimenes* (which see). From *Achimenes*, Seeman, its founder, distinguished it "by its truly infundibuliform, not bilobed, stigma." In habit, the genus suggests *Achimenes hirsuta*, *A. pedunculata*, and *A. multiflora*. In the American trade one species is offered, *S. mexicana*, Seem. (*S. cærulescens*, Hort.). St. erect, hairy; lvs. ovate, hairy, dentate, stout-stalked, opposite; fls. solitary in the axils, stalked, the corolla 2-2½ in. long, the tube inclined or drooping and curved, the wide-spreading 5-lobed limb blue-purple. Lvs. with a metallic luster. B.M. 4743. H.F. II. 3:160 (as *Shuria mexicana*). Gt. 2:354. This will be found under its accepted name *Achimenes Scheerii*, Hemsl., in the supplementary list, Vol. I, p. 208.

L. H. B.

SCHEFFLERA (named after G. C. Scheffler). Including *Heptapleurum*, *Paratropia*, and *Sciadophyllum*. *Araliaceæ*. Glabrous or pubescent trees or shrubs or sometimes climbing by means of switch-like branches, grown in the greenhouse or hardy in the far South.

Leaves various, mostly digitately compound, rarely simple and then usually mixed with compound lvs., very seldom double digitately compound; fls. in umbels, heads, or racemes, these mostly arranged racemously, seldom in whorls; calyx-limb weakly developed, obscurely and shortly toothed or almost lacking; petals 5 or more (—15), mostly 5-6; stamens as many as the petals; fr. globose to ovate or elongated, sulcate or angled.—About 150 species in the tropical regions of the world. *Paratropia Stelzneriana*, Barb.-Rodr., belongs to this genus. See under *Paratropia*.

odorata, Merr. & Rolfe (*Polyscias odorata*, Blanco). A glabrous vine 6-18 ft. high;

petioles longer than the lfts.; lfts. 5 or 6, smooth and shining, coriaceous, elliptic to broadly ovate, obtuse or very shortly acuminate; panicles lax, terminal; fls. greenish, 6-merous; fr. globose, fleshy. March, April Philippines.—Occasionally cult.

S. acuminata, Harms (*Actinophyllum acuminatum*, Pav. *Sciadophyllum acuminatum*, Poir.), has climbing sts. 10 ft. high, 7-11 oblong, obliquely acuminate, coriaceous lfts. and yellow fls. in small heads. May. Peru.—*S. conica*, Harms (*Actinophyllum conicum*, Pav. *Sciadophyllum conicum*, Poir.), has shrubby sts. 10 ft. high, 7-13 oblong, abruptly acuminate, coriaceous lfts., and small heads of whitish red fls. May. Peru.—*S. polybotrya*, Viguier (*Paratropia polybotrya*, Miq. *Heptapleurum polybotryum*, Seem.), is a sparingly branched shrub, 5-7 oblong-ovate to obovate-oblong, caudate-acuminate lfts. and long racemes of small green fls. Winter. Java. B.M. 6238.—*S. Sciadophyllum*, Harms (*Aralia Sciadophyllum*, Sw. *Sciadophyllum Brownii*, Spreng.), has tree-like sts. 10-15 ft. high, 7-11 nearly umbellate oblong-lanceolate, glabrous unequal lfts. and white fls. in heads which are in long compound racemes. Peru.—*S. venulosa*, Harms (*Paratropia venulosa*, Wight & Arn. *Heptapleurum venulosum*, Seem.), is a small glabrous tree or climbing shrub with glabrous entire acuminate lfts. and small compound panicles of greenish fls. India. Var. *erythrostachya*, Hort., differs in having very large lvs., with broad lfts. and very tiny deep red fls., borne in a branched terminal panicle. Trop. Asia. B.M. 7402.—*S. vitiensis*, Seem. (*Aralia vitiensis*, Gray. *Agalma vitiensis*, Seem.), has digitate lvs., obovate-oblong, obtuse entire lfts., with horizontally spreading veins and 3-7 fls. in an umbel. Fiji Isl.

F. TRACY HUBBARD.

SCHIMA (said to be an Arabian name). *Ternstroemiaceæ*. Evergreen trees or shrubs, suitable for the warm-house; peduncles 1-flid., solitary in the axils or above crowded in a short raceme; fls. showy; sepals 5, slightly unequal; petals 5, much larger, connate at base, strongly imbricate, the outermost concave or somewhat hooded; stamens numerous; ovary 5- (rarely 4-6) celled; caps. ligneous, commonly depressed-globose.—About 9 species, Trop. Asia. Here belongs a neat little tea-like shrub about 2 ft. high, known to the trade as *Gordonia javanica*. *Schima* and *Gordonia* are closely related genera, distinguished by Bentham and Hooker as follows: *Schima* has inferior radicles, sepals scarcely unequal, ovules few in each locule and laterally affixed; *Gordonia* has superior radicles, sepals markedly unequal, ovules numerous in each locule and pendulous.

NORONHÆ, Reinw. (*Gordonia javanica*, Rollison). Tender evergreen shrub, 2 ft. high or perhaps more, branched, glabrous; lvs. alternate, elliptic-lanceolate, coriaceous, entire; fls. solitary in the axils, white, 1½ in. across, shorter than the lvs.; petals obovate. Java. B.M. 4539. J.F. 1:46.—A good pot-plant for the warm-house. Readily increased by cuttings.

F. TRACY HUBBARD.†

SCHINUS (Greek name for the mastic-tree, *Pistacia Lentiscus*; applied to this genus on account of the resinous mastic-like juice of some species). *Anacardiaceæ*. Resinous dioecious trees, one much planted in California.

3567. *Schinus Molle*, the California pepper-tree.

Leaves alternate, pinnate; lfts. sessile, axillary: panicles terminal, bracteate: fls. small, whitish, with short, 5-lobed calyx, 5 imbricated petals, broad annular disk, and 10 stamens: fr. a globose drupe.—About 17 species, all S. American except one in the Hawaiian Isls., one in Jamaica, and one in St. Helena. Only two are cult.; they are semi-tropical and grown in the warm-house at the E. and in N. Eu., in the open at the S. and in Calif., as far north as the San Francisco Bay region. *Molle*, the old generic name, is from Mulli, the Peruvian name of *S. Molle*, and not, as sometimes supposed, Latin *molle*, soft, which would not be applicable in this case.

Schinus Molle is everywhere present in southern California, where it attains a height of 50 feet and sows itself. It was a great thing for this region in years past before the water systems had reached their present efficiency. Now the pepper-tree is under a ban, and justly so. Next to oleander the pepper-tree is most subject to black scale. Hence the pepper-trees, being large and numerous, have been indirectly a serious menace to the orchards of citrous fruits. Thousands of old trees, 2 to 3 feet in diameter, have been cut because of their proximity to orange orchards. Los Angeles boasts some magnificent avenues of them. *S. terebinthifolius* is but little known in this region, the tallest tree being only 15 feet as yet, but it is likely to be extensively planted in the near future. (Ernest Branton.)

Mölle, Linn. PERUVIAN MASTIC-TREE. CALIFORNIAN PEPPER-TREE. Figs. 3567, 3568. Evergreen tree, 20 ft. and more, with rounded outline and graceful, pendulous branchlets when not trimmed: lvs. 9 in. or more long, glabrous, of many alternate, linear-lanceolate lfts. $1\frac{1}{2}$ –2 in. long: fls. in conical panicles, yellowish white: ripe frs. the size of peppercorns (whence the popular, but misleading, Californian name), of a beautiful rose-color. Peru. G.F. 8:505. R.H. 1889, p. 225. G.C. III. 17:588, 589. Gn. 25, p. 418. B.M. 3339.—In S. and Cent. Calif. more extensively cult. than any other ornamental tree except, perhaps, the blue gum (*Eucalyptus globulus*), and thriving best in the warm interior valleys, though hardy on the coast at San Francisco. Valued as a lawn and avenue tree; often planted as a street tree, for which, however, it is unsuited, being too spreading and branching too low. *Molle* was a generic name used by Tournefort, and placed in apposition with *Schinus* by Linnæus (explained above).

terebinthifolius, Raddi, with racemose fls., lvs. composed of 7 broader, somewhat serrated lfts. and scarlet berries, is sparingly met with in cult. in S. Calif., and proves hardy in San Francisco. Brazil.

dependens, Ort. (*Duvauia dependens*, DC.), is a shrub or small tree, with more or less drooping branches: lvs. $\frac{1}{8}$ –1 in. long, oblong or obovate: fls. yellow, 1 line long, produced in great numbers in racemes about as long as the lvs.: berries black. W. S. Amer. B.M. 7406. B.R. 1568 (*Duvauia ovata*); 1573 (*D. dependens*); 29:59 (*D. longifolia*).—The berries are said to be used medicinally in Argentina. The genus *Duvana* was distinguished from *Schinus* chiefly by its simple foliage, but it is now considered a subgenus of *Schinus*.

JOS. BUETT DAVY.

SCHISMATOGLÓTTIS (Greek, *falling tongue*, referring to the fact that the limb of the spathe soon falls off). *Araceæ*. Herbs, with stoloniferous rhizomes and the caudex above ground, grown in the warmhouse and also adapted to culture in the dwelling where a day temperature of 70° can be maintained throughout the winter.

Leaves oblong or ovate-cordate, rarely hastate or lanceolate, frequently marbled, maculate, or striped; petiole sheathing at base or nearly to the middle: peduncles solitary or fascicled: spathe cylindrical; spadix sessile, included in the spathe, upper portion male which is cylindrical or clavate, lower portion female, shorter or narrower, cylindrical or conical,

sometimes the two are interrupted by an aborted male area: fls. monœcious, male perianth none; stamens 2–3, distinct; female perianth none, staminoids if present few, ovary oblong.—About 75 species, mostly natives of the Malay Archipelago. Monographed by Engler in Engler's *Pflanzenreich*, hft. 55 (IV. 23Da), 1912.—Among the

3568. Foliage and fruit of *Schinus Molle*. ($\times \frac{1}{2}$)

finest variegated foliage plants of the arum family and hardly if at all inferior in beauty and ease of cult. to the popular *dieffenbachias*, which they closely resemble. For cult. see *Philodendron*, to which the genus is somewhat closely allied.

A. Petiole shortly and broadly sheathed only at base.

tecturata, Engler (*Colobogynium tecturatum*, Schott. *S. variegata*, Hook.). Lvs. oblong-lanceolate, obtuse or rounded at the base, long-cuspidate at apex, dark green above, marked whitish along the midrib; petiole 3–4 in. long or less than half the length of the blade. Borneo.—This species has been confused in the trade with *S. neoguineensis*.

AA. Petiole long-sheathed below.

B. Blade oblong-lanceolate; caudicle erect.

concinna, Schott (*S. Lavallei*, Lind.). Lvs. lanceolate or lanceolate-oblong, rounded or narrowed at the base but not cordate, blotched with silvery white, some of the blotches much larger than others; petiole 6–8 in. long; blade $5-7 \times 1\frac{1}{8}-2\frac{1}{4}$ in.; sheath reddish. Malaya. I.H. 28:418. Var. *immaculata*, N. E. Br. (*S. Lavallei* var. *Lansbergiana*, Lind.), differs in having purple sheaths and lf.-stalks, and foliage green above, dark wine-purple below. Var. *purpurea*, N. E. Br., is a Sumatran form with foliage blotched gray above and dark wine-purple beneath.

BB. Blade ovate, about $1\frac{1}{2}$ times longer than broad; base emarginate or subcordate.

c. The petiole longer than blade.

d. Upper surface of blade ashy-blotched.

púlchra, N. E. Br. (*S. decora*, Bull.). Lvs. ovate obliquely cordate, irregularly blotched with silvery

white, the total mass of green being less than the variegation; petiole 3-4½ in. long; blade 4-5 x 1¼-2½ in. Borneo. I.H. 31:520. G.C. II. 24:361.—*S. decora* var. *Wittmaniana* was offered in 1893 by John Saul, Washington, D. C.

DD. *Upper surface of blade ashy-striped.*

longispátha, Bull. Lvs. ovate, base slightly cordate, apex acuminate, upper surface broadly ashy-white-striped in the middle, otherwise green; petiole 1½ times as long as the blade. Borneo. I.H. 29:466.

CC. *The petiole about equaling the blade and verrucose.*

asperata, Engler. Caudex short: lvs. ovate or obovate, base cordate or only emarginate, apex acuminate, upper surface green with minute white dots, lower pale black-dotted; petiole about as long as blade. Borneo. Var. *álbo-maculata*, Engler (*S. crispata*, Hook.), has the upper surface of the lvs. silvery with the exception of the midnerve, the lateral nerves, and the margins, which are green. Borneo. B.M. 6576.

BBB. *Blade ovate-oblong or its outline more or less triangular and cordate or rarely cordate-ovate, sometimes varying in the same specimen.*

C. *Adult st.-blades oblong-ovate, base distinctly cordate; blade ashy-maculate.*

neoguineensis, N. E. Br. (*S. novoguineensis*, Engler. *S. variegata*, Hort., not Hook.). Lvs. ovate-cordate, bright green, irregularly blotched with pale yellowish green, the total mass of green being greater than the variegation; petiole 9-12 in. long; blade 8-9 x 5-5¼ in. New Guinea. I.H. 27:380 (as *Colocasia neoguineensis*, the variegation being a bright creamy white).

CC. *Adult st.-blades t'rin, broadly ovate-cordate, white or palely ashy-maculate.*

pícta, Schott. Lvs. ovate-cordate, the basal lobes short, but the sinus deep, dark green above, marked with lacerated glaucous spots at the middle, on each side of the midrib, and between the nerves; petiole 8-16 in. long; blade 6-7 in. long. Java.

BBBB. *Blade broadly ovate-cordate, slightly longer than broad, posterior lobes semi-ovate.*

latifolia, Miq. (*S. rupéstris*, Zoll. & Mor.). Caudex thick, above ground: lvs. ovate, acute, deeply cordate, 6-18 x 6-12 in., upper surface dull green, lower paler, posterior lobes semi-ovate, sinus acute; petiole usually longer than the blade. Java, Celebes, and the Philippines.

S. oblongifolia var. *Curtisii*, Hort., is offered in the trade but is apparently not known botanically.—*S. Roebelinii*, Pitcher & Manda, 1895, p. 138. "Lvs. beautifully marked with silvery white in a broad feathery variegation. Only the center and edge of the lvs. are plain light green. The plant is compact, free-growing, with thick lvs. as enduring as those of a rubber tree. A fine house plant." This plant is imperfectly known. It is figured in Pitcher & Manda's catalogue for 1895: 141 as *S. Roebelinii*, and the same is used in A.G. 19:589 (1898) as *S. picta* and in V. 23:71 (1899) as *S. crispata*. The plant so pictured is distinct from any species described above. There is more white than green in the lf., only the edges and midrib portion being green. Some growers think it to be a sport of *S. asperata* var. *álbo-maculata*.—*S. Seemianii*, Hort. Bull., was advertised by the U. S. Nursery Co. 1895, but seems unknown to botanists.—*S. siamensis*, Hort. Bull., imperfectly known to botany. Possibly a species of *Aglaonema*.

F. TRACY HUBBARD.†

SCHÍSMUS (Greek, *schisma*, a cleft, referring to the 2-lobed lemma). *Gramíneæ*. Low annuals with short dense panicles of pale shining spikelets. Species 4, Medit. region and Afr. *S. calycinus*, Coss., has recently been intro., but is of no horticultural importance.

A. S. HITCHCOCK.

SCHIZÆA (Greek, to split). *Schizæacææ*. A group of small ferns with twisted grass-like lvs. and sedge-like sporophylls formed of a cluster of closely compacted pinnae, each with 2 rows of sporangia, which in common with the family are pear-shaped, with an apical ring, opening by a vertical fissure.

pusilla, Pursh. Our only native species, growing in sand at the edges of bogs, mainly in N. J. Lvs. 1 in. long, grass-like, twisted sporophylls 2-3 in. long, with the apex expanded and consisting of 6-8 closely compacted divisions. Known locally as curly-grass. The prothallus resembles the protonema of a moss, being filamentous rather than thallose as in ordinary ferns.

L. M. UNDERWOOD.

SCHIZÁNDRA (Greek, *schizein*, to cleave, and *aner*, *andros*, man, stamen, referring to the cleft or separate anther-cells). Including *Sphæróstema* and *Maximowiczia*. *Magnoliacææ*. Ornamental vines grown chiefly for their handsome bright green foliage and the scarlet or orange-red berry-like fruits.

Deciduous twining shrubs: lvs. alternate, long-petioled, entire or denticulate, exstipulate: fls. slender-stalked, in few-fl. axillary clusters, diœcious or monœcious; sepals and petals 9-12, not differing; stamens 5-15, more or less connate: carpels numerous, imbricated in the fl., developing into berries disposed on the elongated filiform receptacle, forming a drooping raceme.—Ten or 12 species in E. Asia from N. China and Japan to the Malay Archipelago and one species in N. Amer. The frs. of the Asiatic species are eaten in their native countries.

These are handsome vines mostly twining to the height of 10 to 20 feet, with bright green medium-sized, generally ovate or elliptic, slender-stalked leaves and with axillary long-stalked usually cup-shaped white or red flowers followed by showy scarlet or red, rarely black, berry-like fruits forming drooping racemes. *S. chinensis* is hardy North, while the other Chinese species are somewhat tenderer; the native *S. coccinea* can be grown only South. They may be used for covering rocks, trees, shrubs, or fences, and seem to thrive best in partly shaded and somewhat moist places in a porous, sandy loam. To enjoy the very showy fruit which ripens at the end of August or in September, both sexes must be planted together, as most species are diœcious. Propagation is by seeds, by greenwood cuttings under glass, root-cuttings or layers, and also by suckers.

coccinea, Michx. High-climbing shrub: lvs. slender-petioled, ovate or oval, acuminate, entire or obscurely denticulate, glabrous, 2-3½ in. long: fls. monœcious, crimson-purplish, ½-½ in. across; stamens 5, connate into a 5-lobed disk with the anther-cells widely separated: berries scarlet, forming a loose raceme 2-3 in. long. June. S. C. to E. Texas. B.M. 1413.

chinensis, Baill. (*Maximowiczia sinensis*, Rupr.). Climbing to 25 ft.: lvs. broadly oval or ovate, acute or acuminate, remotely denticulate, dark green and shining above, glabrous except at the veins beneath, 2-4 in. long; petiole ½-1½ in. long: fls. diœcious, pinkish white, ½ in. across, fragrant; stamens 5, divided at the apex: berries scarlet, forming a rather dense raceme 1-4 in. long. May, June. Japan, N. China, Amurland. Gt. 12:382. F.S. 15:1594. Gn. 6, p. 583. M.D.G. 1899:568. G.C. III. 50:2. Var. *rùbra*, Hort., is probably *S. rubriflora* (see below).

S. glaucescens, Diels. Similar to *S. chinensis*: lvs. oval to elliptic, denticulate, glaucescent beneath: fls. orange-red: fr. scarlet. Cent. China.—*S. grandiflora*, Hook. f. & Thoms. Lvs. elliptic, denticulate: fls. earmine or pink, 1 in. across: fr. red. Himalayas, W. China.—*S. Henryi*, Clarke. Branches winged: lvs. broadly ovate to elliptic-ovate, glaucescent beneath: fls. creamy yellow, on pedicels 2-3 in. long. Cent. China. G.C. III. 38:162.—*S. nigra*, Maxim. Similar to *S. chinensis*: lvs. smaller, quite glabrous: fls. white: fr. bluish black. Japan. Seems more tender than *S. chinensis*.—*S. propinqua*, Hook. f. & Thoms. (*Sphæróstema propinquum*, Blume). Lvs. ovate to ovate-lanceolate, about 4 in. long on ½ in.-long petioles: fls. pale yellowish: fr. scarlet, forming racemes to 6 in. long. Himalayas. B.M. 4614. For cult. in subtropical regions or in the warm greenhouse. Var. *sinensis*, Oliver. Lvs. oblong to lanceolate, remotely dentate. Cent. and W. China.—*S. pubescens*, Hemsl. & Wilson. Lvs. broadly elliptic to ovate, remotely denticulate, pubescent beneath, 3-4 in. long: fr. red and orange in racemes about 4 in. long. Cent. China.—*S. rubriflora*, Rehd. & Wilson. Lvs. obovate to oblong-obovate, denticulate: fls. dark red, about 1 in. across: fr. crimson, in long racemes. W. China.—*S. sphenan-*

thëra Rehd. & Wilson. Similar to *S. chinensis*: lvs. obovate or elliptic, glabrous: fls. orange-red, $\frac{3}{4}$ in. across; stamens many: fr. scarlet. Cent. and W. China. Var. *lanceifolia*, Rehd. & Wilson. Lvs. lanceolate, minutely denticulate: fls. smaller. W. China.

ALFRED REHDER.

SCHIZÁNTHUS (Greek, *split* and *flower*; from the incised corolla). *Solanaceæ*. BUTTERFLY FLOWER. Erect half-hardy annual herbs, more or less glandular-viscid, grown outdoors and also in the greenhouse for bloom. They can be trained into immense pot subjects.

Leaves frequently pinnatisect, the segms. incised or dentate: cymes terminal and open: fls. incised, showy and variously colored; calyx deeply 5-cleft, almost 5-parted, the lobes linear; corolla-tube short or elongated, cylindrical, the limb spreading, oblique, somewhat 2-lipped, lacinate; perfect stamens 2, exserted; disk inconspicuous; ovary oblong, 2-celled: caps. membranaceous-chartaceous; seeds numerous.—About 7 species, all from Chile. These choice plants are of easy cult. in any good garden soil. They are also useful as pot-plants for spring flowering, the seed being sown in early fall and the plants kept in a light house and given plenty of root-room as they need it. There is a strain offered in trade under the name of *S. hybridus*, Hort., which is not readily placed botanically. It does not appear to be specific in rank and apparently consists of a series of large-fl. garden hybrids. It is offered in several variations.

A. Corolla-tube as long as the calyx; stamens short-exserted.

B. Middle segm. of the anterior lip of the corolla notched at summit.

retusus, Hook. St. 2 ft. high: lvs. pinnatisect, with the segms. entire, dentate, or pinnatifid: fls. in the type deep rose, with the large middle segm. of the upper lip orange except at the tip; the lateral segms. of the posterior lip falcate, acute, linear, longer than the middle segm. B.M. 3045. B.R. 1544. G. 5:361; 23:35. G.M. 51:416. H.F. 1:136. Var. *álbo-maculatus*, Hort., is a form with white-spotted fls. Var. *álbus*, Hort., has the fls. white with the middle segm. of the upper lip suffused with yellow. Gn. W. 17:458. Var. *lilacinus*, Hort., has lilac fls. Var. *nānus*, Hort., a dwarf form, is offered in the trade. Var. *trimaculatus*, Hort. (*S. trimaculatus*, Hort.), has the fls. purple-crimson with 3 distinct golden yellow spots bordered with bright purple. R.B. 32, p. 61.

BB. Middle segm. of the anterior lip not notched at apex.

Grahamii, Gill. Lvs. 1-2-pinnatisect; segms. entire or dentately pinnatifid: fls. typically lilac or rose, with the middle half of the middle segm. of the anterior lip yellow or orange; the lateral segms. of the posterior lip falcate, linear, acute, shorter than the middle segm. B.M. 3044. R.H. 1843:529. H.F. 1:136. Var. *álbus*, Hort., has white fls. Var. *carmineus*, Hort., has carmine fls. Var. *carneus*, Hort., is offered in the trade and has flesh-colored fls. Var. *lilacinus*, Hort., has lilac fls. Var. *niveus*, Hort., has pure white fls. Var. *rōseus*, Hort., has rose-colored fls.

AA. Corolla-tube shorter than the calyx; stamens long-exserted (not noticeably so in *S. wisetonensis*).

wisetonensis, Hort. (*S. pinnatus* × *S. Grahamii*). Apparently intermediate between the two parents, the fl. resembling that of the latter parent in outline, the corolla-tube seemingly shorter than the calyx, the stamens usually rather short-exserted, the fls. vary in color from white through bluish and pink to carmine-brown, the midlobe of upper lip often suffused with yellow. A hybrid of garden origin now very generally cult. G. 25:161; 28:225; 33:351. G.M. 43:332; 53:164. Gn.M. 13:76. Gt. 53, p. 326; 54:1544. G.W. 6, pp. 38, 39. J.H. III. 64:321. R.B. 27:169. C.L.A. 19:166. F.E. 23:646. Var. *compacta*, Hort., is only a more compact form than the type.

pinnatus, Ruiz & Pav. (*S. pōrrigens*, Graham. *S. Priestii*, Paxt.). Fig. 3569. The most variable of the species, with many horticultural forms distinguished by height of st. and color-markings of the fls. Typically 2 ft. high: lvs. 1-2-pinnatisect; the segms. entire, dentate or incisely pinnatifid: fls. varying in depth of color, the lower lip usually violet or lilac; the upper paler, its middle section with a yellow blotch at its base and spotted with purple or violet. B.M. 2404; 2521. B.R.

725; 1562 (as var. *humilis*). Gng. 12:613. G.W. 3, p. 497.—The plant known horticulturally and in trade-lists as *S. grandiflorus*, Hort., and variations, undoubtedly belongs here.

Var. *álbus*, Hort.

(*S. grandiflorus álbus*, Hort.), has fls. slightly larger than the type, white or yellowish. Var. *candidissimus*, Hort., has pure white fls. Var. *compactus*, Hort., is a compact form similar to var. *nānus*, and offered in several forms in the trade. Var. *lilacinus*, Hort., has lilac fls. Var. *nānus*, Hort., is dwarfier than the type, offered in several colors in the trade. Var. *niveus*, Hort., has pure white fls. Var. *oculatus*, Hort. (*S. grandiflorus oculatus*, Hort.), has a purplish black blotch surrounded with yellow at the base of the middle segm. of the upper lip or with the typical yellow portion dotted with small

3569. *Schizanthus pinnatus*. (X $\frac{1}{2}$)

dark purple spots. B.H. 1862:451. H.F. II. 2:264. Var. *papilionaceus*, Hort., has a central coloring somewhat as var. *oculatus*, with the general color of the fl. marbled in various shades. Var. *rōseus*, Hort., has rose-colored fls. Var. *tigridioides*, Hort., is also cult.

F. TRACY HUBBARD.†

SCHIZOCÁPSA (Greek, *cut* and *capsule* or *fruit*). *Taccææ*. Perennial herbs: root tuberous: lvs. radical, entire, nerved: scape undivided, the fls. umbellate, pedicelled; perigonium-tube connate with the ovary, the limb superior, 6-parted, unequal, finally deciduous; stamens 6; ovary 1-celled with 3 parietal placentæ: caps. 1-celled, dehiscent along the angles into 3 valves which are soon recurved. One species, China, *S. plantaginea*, Hance. Plant entirely glabrous: lvs. rather broad, lanceolate, entire, acute, 8-9 in. long, gradually narrowed to a short basally sheathing petiole: infl. umbellate, 15-20-fl.: fls. angled-pedicelled, yellowish green: caps. trigonous, vertically convex-complanate. China. G.W. 4, p. 169.

SCHIZOCÉNTRON (Greek for *split* and *thorn*). *Melastomææ*. A monotypic genus, the species being *S. elegans*, Meissn. (*Heëria elegans*, Schlecht. *Heëria procumbens*, Naudin. *Heterocentron elegans*, O. Kuntze). A low creeping vine-like plant forming a dense carpet, rooting at the joints: branches terete or near so, reddish, somewhat appressed-pubescent: lvs. ovate, distinctly petioled, obtuse: fls. solitary and terminal on slender peduncles, less than 1 in. long; corolla a deep

purple, nearly 1 in. broad: fr. very hairy, producing seed freely by which the plant is readily prop. (or by cutting). Vera Cruz, Mex. G.C. III. 42:293. Gt. 62, p. 275. This species, although first described in 1839, has not been in cult. until since its rediscovery in 1901 at Jalapa by J. N. Rose. It is a very dainty plant, well worthy of ornamental cult. It is grown to some extent in Mexican gardens at an elevation of about 3,000 ft., where it does unusually well, growing apparently as well in shade as in the bright sunlight. The plant has been grown for a number of years in the N. Y. Botanical Garden, and when in full flower makes a most striking display. It forms a dense mat and is well suited for close carpet-bedding.

J. N. ROSE.

SCHIZOCODON (Greek *cut* and *bell*, referring to the fringed corolla). *Drapensiaceæ*. Glabrous herbs, with the caudex perennial and scale-bearing between lvs., suitable for outdoor planting: lvs. all radical, long-petioled, ovate-rotund, base cordate, crenulate-undulate, leathery and persistent: fls. few at the top of the scape, racemose, subsecund, nodding, 1-2-bracted; calyx 5-parted, the segms. linear-oblong, striate-nerved; corolla

3570. *Schizocodon soldanelloides*. (×½)

funnel-form, 5-lobed, the lobes truncate, fimbriate, and imbricate; stamens 5; ovary ovoid-globose, 3-celled: caps. globose, 3-angled.—Perhaps 4 species, Japan. *S. soldanelloides* is a pretty alpine plant or boreal with rosy fls. fringed like the well-known soldanellas of the Alps. It may be readily distinguished from *Soldanella* (which is a member of the primrose family) by the lvs. being toothed, and the stamens 4 instead of 5. The name "fringed soldanella" has been proposed for *schizocodon*, but all soldanellas are fringed. "Fringed galax" would be better, as galax is the nearest relative, *schizocodon* being, in fact, the Japanese representative of the American galax. The lvs. of *schizocodon* are sometimes more or less bronzy, like those of galax, but their form is not so pleasing. The plant is only a few inches high, and the fls. are borne to the number of 4-6 on a scape. The scapes are numerous and the fls. about 1 in. across. Since 1892 this plant has excited an amount of interest comparable to that caused by the intro. of *shortia*, in 1889.

soldanelloides, Sieb. & Zucc. FRINGED GALAX. Fig. 3570. Hardy, tufted, alpine plant a few inches high: lvs. leathery, evergreen, long-stalked, the blade roundish, wedge-shaped or subcordate at the base, coarsely toothed, the teeth apiculate: fls. nodding; sepals 5, oblong, obtuse; corolla deep rose in center passing into

blush or white at the edges; staminodes linear. Japan. B.M. 7316. Gn. 44:418. G.C. III. 13:415; 51:348. G.M. 36:206. J.H. III. 34:323; 44:347. V. 20:119.—This is probably the only species in the genus, as *S. uniflorus* is *Shortia* and *S. ilicifolius* is thought to be a variety of *S. soldanelloides*, with more variable lvs. and fls. ranging from red to white. Offered by many European dealers, and by one or two Americans; little known here.

F. TRACY HUBBARD.†

SCHIZOLÒBIUM (Greek, *to cleave* and *pod*, alluding to the manner of dehiscence). *Leguminosæ*. Tall trees adapted to the warmhouse and planted outdoors in the extreme South: lvs. large, bipinnate; lfts. numerous, small: fls. in axillary racemes or in panicles at the ends of the branches; calyx-tube disk-bearing, oblique, turbinate, the segms. slightly unequal, reflexed; petals 5, clawed, ovate or rotundate, slightly unequal; stamens 10, free; ovary scarcely stipitate; legume compressed, obovate, 2-valved, 1-seeded.—One, possibly 2, species. Brazil and Panama.

excelsum, Vog. A tree reaching a height of 120 ft. in its native habitat: lvs. fern-like, with 18 pairs of lfts. which are about 2 in. long and 20-jugate, oblong, very short-petiolulate, white beneath and golden pilose on the midnerve: fls. yellow, in large panicles. Brazil. R.H. 1874, p. 113.—Intro. into S. Fla. and S. Calif.

F. TRACY HUBBARD.

SCHIZONÔTUS: *Holodiscus*.

SCHIZOPÉTALON (Greek, *cut* and *petals*, alluding to the cut petals). *Cruciferae*. Half-hardy erect annual herbs used in border planting: lvs. alternate, sinuate, dentate or pinnatifid: fls. purple or white, in terminal, leafy-bracted racemes; sepals erect; petals clawed, pinnate-lobed, involute: silique narrowly linear, knotty; seeds many.—About 10 species, S. Amer. *S. Walkeri*, Sims. St. weak, assurgent: lower lvs. 4-5 in. long, sinuate-pinnatifid, elongate-oblong in outline, long-attenuate at base, scabrous on both surfaces, distant: peduncles solitary, axillary, but collected at the top into a raceme: fls. white; calyx cylindrical; petals spreading, ovate, incise-pinnatifid. Chile. B.M. 2379. G. 24:240.

SCHIZOPHRÁGMA (Greek, *schizein*, to cleave, and *phragma*, wall; the inner layer of the wall of the valves is cleft into fascicled fibers). *Saxifragaceæ*. Ornamental vines grown for their handsome bright green foliage and their showy clusters of white flowers.

Shrubs climbing by aerial rootlets: lvs. opposite, long-petioled, dentate or entire: fls. in loose cymes; sepals and petals 4-5; stamens 10; style 1; ovary 4-5-loculed; marginal sterile fls. consist only of 1 large white sepal, terminating the branchlets of the infl.: fr. a small, 10-ribbed caps.—One species in Japan and another in China, allied to *Hydrangea* and *Decumaria*.

These are handsome woody vines with rather large bright green foliage and loose terminal cymes of small white flowers with large and showy sterile ones at the margin. They are well adapted for covering walls and trunks of trees and cling firmly by means of aerial rootlets. The Japanese species is hardy as far north as New York City, while the Chinese one is tenderer. They thrive best in rich, moderately moist soil and partial shade, but also do well in full sun if the soil is not too dry. Propagation is by seeds or greenwood cuttings under glass; also by layers.

hydrangeoides, Sieb. & Zucc. Climbing to 30 ft. and more: lvs. on reddish petioles 2-3 in. long, orbicular or broadly ovate, shortly acuminate, rounded or cordate at the base, remotely and coarsely dentate, bright green above, pale beneath, almost glabrous, 2-4 in. long: cymes peduncled, 8 in. broad; marginal fls. pedicelled, consisting of an oval to broadly ovate white

sepal about $1\frac{1}{2}$ in. long. July. Japan. S.Z. 1:26, 100. Gn. 15, p. 301; 34, p. 281. R.H. 1881, p. 313, fig. 72. B.M. 8520.—The species is often confounded with *Hydrangea petiolaris*, which is easily distinguished by its marginal fls. having 4 sepals. Like *Hydrangea petiolaris*, young plants produce small lvs. and make little growth if unsupported and allowed to trail on the ground. It has been once intro. under the name *Cornidia integerrima*, which is a Chilean plant with entire evergreen lvs.

integrifolium, Oliver (*S. hydrangeoides* var. *integrifolium*, Franch.). Climbing to about 12 ft.: lvs. ovate or broadly ovate, acuminate, truncate or subcordate at the base, entire or sparingly denticulate, usually pubescent on the veins beneath, of thickish texture, 4–6 in. long; cymes to 10 in. broad; the sepals of the sterile fls. ovate to ovate-oblong, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long. July. W. China. H.I. 20:1934. J.H.S. 28, p. 62. Var. *mölle*, Rehd. Petioles and lvs. beneath densely soft-pubescent; sterile sepals 2–3 in. long. W. China. Var. *denticulatum*, Rehd. Lvs. thinner, broadly ovate to oblong-ovate, minutely or sinuately denticulate, pubescent on the veins beneath; sterile sepals usually ovate-oblong, broadly cuneate at the base, $1\frac{1}{2}$ – $2\frac{1}{4}$ in. long. Cent. China.—This species is showier than the preceding on account of the larger sterile sepals, but is less hardy.

ALFRED REHDER.

SCHIZOSTYLIS (Greek, *to cut*, and *style*, alluding to the filiform segments of the style). *Iridaceæ*. Greenhouse or half-hardy plants: sts. fasciated on the rhizome, bulbous or slightly bulbous-thickened at the base; lvs. linear or narrow-ensiform: spathes remote along the simple peduncle, somewhat distichous, greenish, lanceolate, complicate: fl. sessile in the spathe; bracts narrower than the spathe, green or somewhat scarious, 2-keeled; perianth showy, red, the tube slender, the lobes equal, oblong or ovate; ovary 3-celled: caps. obovoid or oblong, the top truncate, 3-grooved, membranaceous.—Two species, S. Afr.

coccinea, Backh. & Harv. CRIMSON FLAG. A winter-blooming tender plant: st. 1–2 ft. high, bearing 2–3 lvs.: basal lvs. 2–3, about $1\frac{1}{2}$ ft. long; fls. bright red, about 2 in. across. B.M. 5422. F.S. 16:1637. G.L. 24:208. J.H. III. 48:539.—The following cultural notes are taken from Garden and Forest 9:16: "The species blooms from Oct. to late Dec. and is useful for cut-flowers at this season. It is perfectly hardy in England but of little use here except for indoor use. The roots should be planted out in rich soil in spring about 8 in. apart, and encouraged to make a strong growth. In the fall the plants may be lifted, potted and placed in a cool greenhouse, where they will flower. After flowering they may be stored in a frame until spring, when the fleshy roots will need to be separated (leaving 3–5 buds to each root), and planted out as before."

F. TRACY HUBBARD.†

SCHLEICHÈRA (named for J. C. Schleicher, a Swiss botanist). *Sapindaceæ*. Tree of some economic value and hardy in the far south of the U. S.: lvs. alternate, not stipulate, pinnate; lfts. opposite (or alternate), entire, repand-wavy or slightly serrate; infl. simple elongated panicles or racemes: fls. small, fasciated, regular, polygamously dioecious; calyx 4–6-lobed, small, cup-shaped; petals lacking; disk complete, glabrous, wavy; stamens 5–8; ovary 3–4-celled: fr. dry-crustaceous-coriaceous. One species, Asia. *S. trifuga*, Willd. A large tree: lvs. paripinnate, 8–16 in. long; lfts. 4–8, opposite, $1-10 \times \frac{3}{8}-4\frac{1}{4}$ in., elliptic or elliptic-oblong, obtuse or short-acuminate, entire, sessile or subsessile: racemes axillary: fls. yellowish or green: fr. $\frac{3}{4}$ –1 in. long, ellipsoidal, glabrous, apiculate, smooth or spiny. Himalaya region, south through India, Ceylon, Burma, to Java and Timor. Intro. into Calif.—The timber is good, the bark is astringent and when mixed

with oil is used by the natives to cure the itch, the oil of the seed is of economic use, and the subacid pulpy aril is edible.

F. TRACY HUBBARD.

SCHLÏMMIA (named in honor of M. Schlimm). *Orchidaceæ*. Epiphytic herbs, with oblong somewhat spindle-shaped 1-lvd. pseudobulbs, suitable for the warmhouse with cattleyas and the like: lvs. leathery, contracted to the petiole: scapes erect or recurved from between the pseudobulbs, simple, few-sheathed: fls. rather large, fleshy, ivory-white, few in a lax raceme, short-pedicelled; sepals, the dorsal free, narrow, concave-keeled, the lateral very broad, connate with the foot of the column, forming a helmet-like sac; petals narrower than the dorsal sepal, spreading at their tip; labellum variously lobed, the apex reclining on the foot of the column; pollinia 2.—Three species from the Colombian Andes. *S. jasminodora*, Planch. & Lind. Pseudobulbs long and slender: lvs. oval, long-petioled: scape about 1 ft. high bearing 3 second fls.; fls. white and very fragrant; dorsal sepal linear erect; petals reflexed; labellum fleshy, shorter than the column. Colombia. *S. trifida*, Reichb. f. Pseudobulbs elongate-ovate, clustered: lvs. oblong, acute: scape lateral, drooping, deep purple, bearing a 1-sided raceme of about 4 fls.: fls. fragrant; dorsal sepal turned downward, lateral waxy white with a few purple spots inside; petals linear, acute, bent outward; labellum trifid at the apex, white, marked with rich orange. Colombia. G.C. II. 7:141.

F. TRACY HUBBARD.

SCHLUMBERGÈRA (named for Friedrich Schlumberger). *Cactaceæ*. Similar to *Zygocactus* in habit, but with regular fls. and angled fr. Schumann referred some of the species to *Phyllocactus* (*Epiphyllum*), but such a reference can hardly be entertained. The genus seems to be confined to Brazil, but little is known about it in a wild condition. Its treatment should be the same as *zygocactus* (the old *Epiphyllum*). Two well-known species are in cult.

Russelliàna, Brit. & Rose (*Epiphyllum Russelliànum*, Hook.). Sts. more upright, with pendent branches: joints $\frac{3}{4}$ – $1\frac{1}{2}$ in. long by $\frac{3}{8}$ – $\frac{3}{4}$ in. broad, oblong or elliptical to obovate, light green; margins crenate, with 2–4 areoles on either side, bearing a few very short dark gray bristles: fls. from the end of the youngest joints, red, $1\frac{3}{4}$ – $2\frac{1}{4}$ in. long; fr. red, 4-angled or narrow-winged. Brazil. B.M. 3717.

Gärtneri, Brit. & Rose (*Epiphyllum Gärtneri*, Schum. *E. Russelliànum* var. *Gärtneri*, Reg.). **EASTER CACTUS**. Sts. of more upright habit, with drooping branches: joints long-oblong or elliptical to obovate, $\frac{5}{8}$ – $2\frac{1}{4}$ in. long by $\frac{1}{2}$ –1 in. broad, dark green, margins crenate, with about 5 areoles on either side, bearing 6–12 rather stiff, long, yellow or brown bristles, which are especially conspicuous on the truncated apex, where they form a considerable beard: fls. from the apex of the youngest joints, $2\frac{1}{2}$ –3 in. long, scarlet-red: fr. red. Brazil. B.M. 7201.

J. N. ROSE.

SCHËNIA (named in honor of Dr. Schœn). *Compositæ*. An annual, adapted to the greenhouse in the N. and outdoors in the S.: lvs. alternate or the lower ones opposite, entire: fl.-heads in a loose corymb: involucre turbinate or campanulate; outer bracts scarious, imbricate, inner row petal-like; receptacle without scales; florets all tubular, 5-toothed; those of the circumference fertile, the disk-florets sterile.—One species, Austral. *S. Cassiniàna*, Steetz. An erect corymbosely branched annual, 1–2 ft. high: lvs. lanceolate or linear, or the lower oblong-spatulate: fl.-heads in a loose terminal corymb: outer bracts of involucre brown, the radiating laminae of the inner white or pink, oblong: achenes in a single row at the circumference. Austral. J.H. III. 47:7.

SCHOMBOLÆLIA (compounded from *Schomburgkia* and *Lælia*). *Orchidaceæ*. A generic name to designate the hybrids between *Schomburgkia* and *Lælia*. *S. tibicincta* = *S. tibicinis* × *L. tenebrosa*.

SCHOMBOLÆLIOCATTLEYA (compounded from the names *Schomburgkia* and *Læliocattleya*). *Orchidaceæ*. A name to comprise the hybrids between *Schomburgkia* and *Læliocattleya*. *S. schænbrunnensis* = *S. rosea* × *Lc. Lucia*.

SCHOMBURGKIA (named for Dr. Schomburgk, naturalist and geographer, who explored British Guiana). *Orchidaceæ*. Orchids with the habit of cattleyas or lælias, except that they are less compact.

Pseudobulbs long, fusiform, bearing several brown scales and 2-3 leathery lvs. at the summit: fl.-sts. from the top of the pseudobulbs, sometimes very long, bearing a terminal raceme or panicle of showy fls.: fls. like those of *Lælia* except that the sepals and petals are narrow and undulate and the labellum does not completely envelop the column; labellum always evidently 3-lobed.—About 15 species, in Trop. Amer.

3571. *Schomburgkia tibicinis*. ($\times \frac{1}{4}$)

Give schomburgkias plenty of heat and a light place near the glass, which should be slightly shaded during the hot summer months. Provide freely of water in the growing season. Rest them in a temperature of 55°. *S. tibicinis* and *S. Lyonsii* are to be classed amongst the showy easily grown orchids resembling lælias. (Wm. Mathews.)

tibicinis, Batem. (*Epidendrum tibicinis*, Batem.). Fig. 3571. Pseudobulbs 1-1½ ft. long, tapering upward: lvs. 2-3, oblong, leathery: raceme 4-8 ft. high, bearing numerous fls. each 3½ in. across; sepals and petals oblong, undulate, crisp; lateral lobes of the labellum large, cucullate, middle lobe small, emarginate; fls. deep pink, speckled with white on the outside, rich chocolate-red within; labellum white within, deep rose-color at the sides, with a short chocolate-red middle lobe. Summer. Honduras, Cuba. G.C. III. 4:212; 3:651. Var. *grandiflora*, Lindl. Fls. larger and paler, with more yellow in the lip. B.R. 31:30. B.M. 4476.

F.S. 1:54.—*S. tibicinis* requires less compost than the other species.

Lyonsii, Lindl. Pseudobulbs about 1 ft. high, with 2-3 linear-oblong lvs. at the top: racemes erect, 9 in. long, bearing 12-25 fls., each subtended by a reflexed bract about 3 in. long; fls. 2 in. across; sepals and petals ovate to ovate-lanceolate, undulate, white with several rows of purple spots; labellum larger, recurved, acute, white, with a yellowish brown crisp margin; anther 2-horned. Aug. Jamaica. B.M. 5172. F.S. 20:2130. G.C. III. 26:203.

rosea, Lind. Related to *S. undulata*. Bracts, peduncles and labellum light rose: sepals and petals oblong, undulate, narrower than the labellum; labellum with rotund lateral lobes and a smaller subrotund middle lobe, margin crisp. Colombia.

crispa, Lindl. Pseudobulbs numerous, long: lvs. oblong-lanceolate: fls. yellowish brown; sepals and petals oblong, undulate; labellum ovate-oblong, obscurely 3-lobed. Guiana. B.R. 30:23. B.M. 3729 (as *S. marginata* var.).

undulata, Lindl. Fls. in a dense raceme; sepals and petals linear, undulate, crisp, longer than the labellum, rich brownish purple; labellum cucullate, middle lobe oval, acute or obtuse, violet-purple. Jan. Colombia. B.R. 31:53.

S. Lueddemannii, Prill. Fls. brown, with the lip and column purple, and the crest and anther yellow; sepals and petals linear-oblong, obtuse, manifestly undulate, 1½-1¾ in. long; lip 3-lobed, ½ in. long, the middle lobe ovate-orbicular, apiculate, about ¼ in. long, the edges incurved near apex. Venezuela. B.M. 8427.—*S. Sanderiana*, Rolfe. Fls. rose-carmine; sepals lanceolate-oblong, 1½ in. long; petals oblanceolate-oblong; lip obscurely 3-lobed, 1½ in. long, the front lobe broadly rounded obtuse, crisped-undulate. Origin unknown. J.H. III. 51:383.—*S. Thomsoniana*, Reichb. f. Sepals and petals linear-oblong, 1½ in. long, cream-white passing to yellow at apex, the sepals undulate, the petals crisped; lip 3-lobed, the middle lobe oblong, emarginate, much crisped, deep purple, with a yellow disk. Cayman Isls. B.M. 7815.—*S. Wallisii*, Reichb. f. Resembling *S. Lueddemannii*. Lip with broad obtuse side lobes, and very acute front lobe, all brown at apex.

GEORGE V. NASH.†

SCHOMBURGKIOCATTLEYA (compounded from *Schomburgkia* and *Cattleya*). *Orchidaceæ*. A genus established to contain the hybrids between *Schomburgkia* and *Cattleya*. *S. spiralis* = *S. tibicinis* × *C. Mossiae*.

SCHOTIA (named for Richard Schot, companion of Jacquin during his travels in America, 1754-1759). *Leguminosæ*. Small trees or unarmed shrubs, suitable for greenhouse-growing.

Leaves odd-pinnate; lfts. leathery, or small; stipules short: fls. red, showy, clustered in short panicles; bracts and bracteoles ovate or oblong, caducous; calyx-tube disk-bearing, turbinate, short or the base long-attenuate, segms. 4, strongly imbricated; petals 5, slightly unequal, subsessile, imbricated, either ovate or oblong or minute scale-like; stamens 10, free, or shortly connate at the base; ovary stipitate: legume oblong or broad-linear.—About 6 species, Subtrop. and S. Afr.

A. Fls. on rather long pedicels.

B. Petals longer than the calyx.

speciosa, Jacq. A tree or shrub, about 10 ft. high: lvs. variable in form, which fact has led to much separation of this species into varieties and species; lfts. 8-32, linear, oblong, or obovate: fls. crimson, in terminal panicles. S. Afr. B.M. 1153 (as *S. tamarindifolia*).—Intro. in S. Calif.

BB. Petals shorter than the calyx.

brachypetala, Sond. A large shrub or small tree: lfts. 8-10, larger than in *S. speciosa*, ovate-oblong or obovate: panicles many-fl., axillary and terminal; calyx-tube conical, crimson; petals very small, linear, hidden by the calyx. S. Afr.—Cult. in S. Fla. and S. Calif.

AA. *Fls. nearly sessile.*

latifolia, Jacq. Becoming a tree 20–30 ft. high: lfts. 4–8, ovate-oblong or obovate, usually $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long, $\frac{1}{2}$ –1 in. wide: fls. rosy or flesh-colored, in much-branched panicles; petals longer than the calyx. S. Afr.—Advertised in S. Calif. F. W. BARCLAY.

F. TRACY HUBBARD.†

SCHRÁNKIA (named after F. B. Schrank, a Bavarian botanist); also spelled *Schranckia*. *Leguminosæ*. Perennial herbs or subshrubs, often prostrate, armed with recurved prickles. The species in common cult. is

3572. *Schubertia grandiflora*.
($\times \frac{1}{6}$)

an outdoor plant. Lvs. bipinnate, often sensitive, petiole without glands, frequently bristly between the pinnæ; the lfts. small; stipules bristle-like: fls. in globose heads or cylindrical spikes, peduncles solitary or fasciated at the axils, rose or purplish, 5–4-merous, sessile, perfect or polygamous; calyx very minute; petals connate to the middle in a funnelform corolla; stamens numerous, free; ovary subsessile: legume linear, acute or acuminate, both sides aculeate.—About 10 species, all American; one has also been discovered in Trop. Afr. These plants are also known as *Morongia*, the following species, in that case, taking the name *M. uncinata*, Brit.

uncinata, Willd. SENSITIVE BRIER. A hardy herbaceous perennial, branched and decumbent, 2–4 ft. long, well armed with short prickles: lvs. very sensitive, with about 6 pinnæ; pinnæ with 16–30 lfts.: fls. pink, in globular heads nearly 1 in. through. May–July. Va. to Ill. and south. B.B. 2:256.

F. TRACY HUBBARD.†

SCHREBÈRA (perhaps after J. C. D. Schreber, 1739–1810, physician and naturalist). *Oleaceæ*. Trees with unequally pinnate lvs. and fls. in very much-branched cymes: calyx tubular-bell-shaped, irregularly 4–7-lobed; corolla salver-shaped; tube cylindrical; lobes 4–7, spreading; stamens 2, near the top of the corolla-tube; ovary 2-celled.—About 15 species, Afr. and India. *Nathusia*, with 4 species at the date of Engler & Prantl, *Die Pflanzenfamilien*, IV. 2 (1895), is a synonym of this genus.

swietenoides, Roxbg. (*Nathusia swietenoides*, Kuntze). A tree, about 40 ft. high, nearly glabrous: lfts. 5–7, ovate, acute, 4×2 in.: fls. white, with brown marks, about $\frac{1}{2}$ in. across, in many-fld. cymes. Cult. in S. Fla.

SCHUBÉRTIA (named after Gotthilf Heinrich von Schubert). *Asclepiadaceæ*. Twining shrubs, occasionally grown in the warmhouse: lvs. large: fls. large, white, borne in loose umbels; sepals ovate, generally acute, alternating with single glands; corolla funnelform or salver-shaped, with a broad tube; crown upright, included: follicles thick and hairy.—About 6 species from S. Amer. **S. grandiflora**, Mart. & Zucc. Fig. 3572. Branches twisting, straw-colored, covered with long rigid red-brown hairs: lvs. cordate, obovate, acute, both surfaces densely brown-pubescent: umbels few-fld.; pedicels long-hairy: fls. white; sepals oval-acute; corolla large, tube gourd-shaped, glabrous inside, the lobes oval-elongate, obtuse, erect, sparsely pale yellow pilose Brazil. G. 36:503; 37:351. Gt. 50:1492. G.F. 3:369 (adapted in Fig. 3572). Gn. 32:84. **S. graveolens**, Lindl. (*Araujia graveolens*, Mast.), is a Brazilian climber, likely to be found in collections of greenhouse plants, smaller-fld. than the above. See p. 2610, under *Physianthus*. There may be confusion in the use of the names *S. graveolens*, *S. grandiflora*, and *Physianthus auricomus*.

SCIADÓCALYX: *Isoloma*. The following species was not treated under *Isoloma*, see Vol. III, p. 1705. **Isoloma Warszewiczii**, Hort. (*Sciadocalyx Warszewiczii*, Regel. *Kohleria Warszewiczii*, Hanst.). Perennial herb, 3–4 ft. high, with catkin-like stolons: st., petioles, lvs., and calyx villous-hirsute: lvs. opposite, long-petioled, oval or cordate, crenate: fls. in axillary umbels of 3–6 fls., bright yellow or yellowish green, red- or brown-dotted; calyx adnate to ovary, 5-lobed, lobes almost horizontally spreading; corolla almost oblique at base, tube slightly inflected, limb 5-lobed, lobes rounded; ovary hirsute, surrounded by a glandular, 5-lobed ring. Colombia. B.M. 4843. Gt. 2:256.

SCIADOPHYLLUM (*shade leaf*, because of the umbrageous foliage). *Araliaceæ*. As understood by Benthams & Hooker in *Genera Plantarum*, it is a genus of the American tropics, at that time with about 22 known species, differing from *Schefflera*, among other things, in the calyprate or coherent rather than free petals and sometimes 4-merous fls. Harms, in Engler & Prantl's *Pflanzenfamilien*, refers it to *Schefflera*, and under this name (p. 3108) are here described any species probably now in the trade.

SCIADÓPITYS (Greek, *skias*, *skiados*, umbrella, and *pitys*, spruce, alluding to the position of the leaves). *Pinaceæ*. **UMBRELLA PINE**. Ornamental tree grown for its handsome foliage and regular pyramidal habit.

Evergreen resinous tree: lvs. of two kinds; small and scale-like lvs. scattered on the shoot, but crowded at its end and bearing in their axils a whorl of 20–30 long linear flat lvs. furrowed on each side, more deeply beneath; these lvs. really consist each of 2 connate lvs. borne on undeveloped spurs like those of *Pinus*; they have been sometimes called cladodes, but are not true cladodes: fls. monœcious; the staminate oval, consisting of spirally disposed 2-celled anthers and appearing in dense clusters at the ends of the shoots; the pistillate are solitary at the ends of the shoots and consist of numerous spirally arranged scales subtended by a small bract and bearing 7–9 ovules: cone oblong-ovate, woody, the bracts connate, with the broadly orbicular thick scales spreading at the margin; seeds oval, compressed, with narrow wing, emarginate at the apex.—One species in Japan, with very strong and straight-grained, nearly white wood.

The umbrella pine is a very handsome tree of narrow

3573. Whorls of foliage of *Sciadopitys verticillata*.
($\times \frac{1}{6}$)

pyramidal habit, with linear, rather large, needle-like dark green and lustrous leaves in whorls and oval cones 3 to 4 inches long. It is hardy as far north as Portland, Maine, and is of rather slow growth. It thrives well in a moderately and constantly moist, loamy, and also in clayey soil; in dry soil or in soil which periodically becomes dry, it grows poorly. Propagation is by seeds and layers, and sparingly by cuttings of half-ripened wood in summer; but seedlings are to be preferred, as they grow more symmetrically and more vigorously.

verticillata, Sieb. & Zucc. **UMBRELLA PINE**. Figs. 3573, 3574. Tree, attaining 100 ft., with ascending branches forming a narrow pyramidal compact head, in old age loose and with pendulous branches: scale-like lvs. dark brown, $\frac{1}{6}$ in. long; needles 15–35 in each whorl, linear, stiff, obtuse, and emarginate, deeply furrowed on both sides, dark green and glossy above, with a white line beneath, 3–6 in. long; cone 3–5 in. long, ovate-oblong; seed $\frac{1}{2}$ in. long; cotyledons 2. Japan. B.M. 8050. S.Z. 2:101, 102. F.S. 14:1485, 1486. Gt. 32, p. 149; 37, p. 437. Mn. 4, p. 154. Gng. 1:25. Gn. 28, pp. 204, 205; 38, p. 499; 71, p. 176; 76, p. 144. G.M. 45:97; 47:272. Gn.W. 11:297. F.E. 21:172, pl. 115. M.D.G.

1906:557. R.H. 1884, pp. 16, 17.—There is a dwarf variety and a form with variegated foliage, both intro. from Japan.

ALFRED REHDER.

SCILLA (the old Greek name used by Hippocrates: *I injure*, according to Miller, alluding to the poisonous bulbs). *Liliaceæ*.

SQUILL. WILD HYACINTH. BLUEBELL. Perennial bulbous plants remarkable for easy culture, quick growth and beautiful blue, rose, or white flowers, blooming early in the spring (some in autumn), and therefore desirable plants for the wild-garden, rock-garden, or border; they are very useful in

distinct from the base or very nearly so. Great Britain possesses 3 species of Scilla, *S. verna*, *S. autumnalis*, and *S. nonscripta*, while Germany has, in addition to *S. autumnalis*, 3 others, viz., *S. amœna*, *S. bifolia*, and *S. italica*. For *S. Fraseri*, see *Camassia*.

Among the early flowers there is none more valuable than the scillas. They vary considerably in form of flower and foliage, and although typically they have blue or blue-purple flowers, most, if not all, of the species in cultivation have white and red-purple forms. *S. sibirica* and *S. bifolia* are the earliest to flower, and of these forms the Asia Minor or Taurian kinds are in advance. The form of *S. sibirica* known as *multiflora* is nearly past before the usual type begins to expand. There is also sometimes cultivated in the garden a pleasing white scilla, with hyacinth-like flowers, known to the trade as *S. amœna*. But these white forms are mostly oddities; the effective ones are the blue-flowering kinds. Occasional hybrids between scillas and chionodoxas are met with (see page 749). *Chionoscilla Alleni* is the accepted name for a natural hybrid between *Chionodoxa Luciliae* and *Scilla bifolia*, first obtained by Mr. Allen, of England, in 1891.

None of the hardy squills requires special culture, and if planted where they can remain undisturbed for a series of years, they seldom disappoint one if the soil is occasionally enriched by top-dressings of manure. The writer has grown them distributed in the grass of the lawn for a number of years with considerable success. The bulbs should be planted as early as possible in autumn. The varieties may be increased by offsets taken after the foliage has matured. For the cool greenhouse or conservatory, many of the scillas are ideal subjects. For this culture, five or six bulbs may be put in a 5-inch pot and the vessel afterward transferred to a coldframe and covered until growth commences. Up to this period very little water will be required, but as the flower-cluster appears the quantity should be increased and the pots transferred to the greenhouse, giving them a position near the glass. The foliage matured, the bulbs may be shaken out of the soil and stored. More attention should be paid to the propagation of the scillas by commercial dealers, for these bulbs should become one of the features of the wild-garden in early spring.

The *Urginea Scilla*, sometimes called *Scilla maritima*, needs to be mentioned in this connection on account of its yielding a medicine for many centuries held in esteem. Almost everyone is familiar with sirup of squills, and has obtained relief from its use in severe colds. The scales of the bulb contain mucilage, sinistrin, sugar, and crystals of calcium oxalate (stated by botanists to ward off snails); the active principles are scillipicrin, scillitoxin, and scillin (the latter producing numbness, vomiting, and the like). Scilla bulbs or roots should never be used unless under proper direction, as in their fresh state they are extremely acrid, and might prove dangerous.

The trade names are considerably confused. Many of the so-called horticultural species and races may be united as mere varieties of species that have been defined botanically. The following names are thought to include all those in the American trade, but other species are known to fanciers.

INDEX.

3574. Umbrella pine.—*Sciadopitys verticillata*.

pots for midwinter flowers, for window-boxes and for room-decoration; some are stove plants; some of the South African forms have handsome spotted foliage.

Bulb tunicated, large or small: lvs. radical, 1 to several in number, linear, loriform, lanceolate, oblong or nearly ovate, in *Scilla autumnalis* appearing after the fls.: scape 1 to several, simple, leafless: fls. in racemes, which are several- to many-fld., open, compact or spicate; bracts small, sometimes minute, hyaline: pedicels short or long, sometimes filiform: fls. small or middle-sized (1 in. across), segms. of perianth distinct, perianth blue, porcelain-blue, rose-colored or whitish, open-rotate, cylindric-campanulate, or open-campanulate, segms. persistent for some time; stamens 6, affixed at base or below the middle of the segms.; anthers ovate or oblong, dehiscing longitudinally, introrse; ovary sessile, stigma small, capitate; ovules 2 in each locule, rarely 8–10, ascending: caps. globose; seeds 1–2 in each cell, rarely more; testa black, appressed; embryo small in albumen. —About 80 species, widely distributed in Eu., Asia, and Afr. in temperate districts. The genus is distinguished from *Ornithogalum* chiefly by the color of the fls. and deciduous perianth, from *Hyacinthus* by the segms.

KEY TO THE SPECIES.

- A. Shape of fls. campanulate: color blue, blue-lilac, rose-purple, white.
- B. Pedicels short: bracts linear, in pairs: raceme many-fl'd.: fls. broadly campanulate, produced from April to June..... 1. *nonscripta*
- BB. Pedicels short: bracts in pairs, scarious-hyaline..... 2. *puschkinioides*
- BBB. Pedicels long (1 1/2 in.): raceme equilateral, compact: fls. cylindric-campanulate, produced in May... 3. *hispanica*
- AA. Shape of fls. saucer-shaped to open-rotate.
- B. Color of fls. rose, size small.
- C. Size of fls. small, color rose-purple: raceme dense, 30-60-fl'd.: lvs. linear, fleshy..... 4. *numidica*
- CC. Size of fls. very small (1/8 in. long): raceme dense: scape slender: bracts whitish, minute..... 5. *chinensis*
- CCC. Size of fls. larger (1/2 in. diam.): pedicels long, ascending or spreading: raceme open. July to Sept..... 6. *autumnalis*
- BB. Color of fls. blue or lilac-blue: size larger (3/4-1 in.).
- C. Raceme very dense (100-150-fl'd.), at first conic, then long, compact and broad: scape robust. May. 7. *peruviana*
- CC. Raceme several- to many-fl'd., open: fls. mostly distant.
- D. Lvs. single: raceme about 5-fl'd.: plant small. May..... 8. *monophyllos*
- DD. Lvs. in pairs, cucullate: raceme 3-8-fl'd., ebracteate: perianth blue, reddish, or whitish. March..... 9. *bifolia*
- DDD. Lvs. more than 2.
- E. Foliage very broad-lanceolate: bulb large: raceme many-fl'd. (50-100). April..... 10. *natalensis*
- EE. Foliage large, broad (1/2-1 1/2 in.): margin ciliate-denticulate: racemes many-fl'd., open. Aug..... 11. *hyacinthoides*
- EEE. Foliage lanceolate, sometimes narrowly so.
- F. Number of fls. 1-3..... 12. *sibirica*
- FF. Number of fls. 4-8. March..... 13. *amœna*
- FFF. Number of fls. 6-30: raceme at first conic, then open..... 14. *italica*
- FFFF. Number of fls. 20-60: scapes 1-3: bracts minute, linear, white..... 15. *japonica*
- EEEE. Foliage linear, thick, channeled: raceme 6-10-fl'd.: fls. fragrant. April to May..... 16. *verna*

1. *nonscripta*, Hoff. & Link. (*S. rotans*, Smith. *S. festalis*, Salisb. *S. cœrnea*, Salisb. *Hyacinthus nonscriptus*, Linn.). COMMON BLUE SQUILL. HAREBELL. Lvs. 10-18 in. long, 1/2 in. broad, subacute, concave: scape solitary, tall, stout: raceme 6-15-fl'd.: bracts in pairs: fls. blue, purple, white, or pink, drooping. April-June. W. Eu., Great Britain. B.M. 1461. Among the garden forms are *alba*, white; *carulea*, blue; *lilacina*, lilac-blue; *rosea*, rose- or pink-colored; *cœrnea*, nodding.—This is one of the most beautiful of squills, fragrant, thriving best in somewhat shady and sheltered places. Originally placed in the genus *Hyacinthus*, on account of the general form of the perianth, it was removed to *Scilla* as having the segms. distinct or nearly so, and is now often considered as forming a distinct genus (*Agraphis*, Link; *Endymion*, Dumort.), either alone or with other species which connect it with the other scillas.

2. *puschkinioides*, Regel. Bulb ovate, tunicate: lvs. radical, 2-4, glabrous, broadly linear, obtuse, 2 1/2-3 in. long: scape low, glabrous: pedicels erect, strict, short, base bibracteate; bracteoles scarious, hyaline: perianth campanulate, pale blue, middle nerve deeper blue; base of filaments united; anthers linear-oblong; style filiform. Turkestan.

3. *hispanica*, Mill. (*S. campanulata*, Ait. *S. pátula*, DC.). SPANISH JACINTH. BELL-FLOWERED SQUILL. Lvs. 5 or 6, glabrous, ascending, lanceolate, 1/2-1 in. broad, subobtus, convex at back: scape long: raceme equilateral, compact: fls. cylindric-campanulate; perianth usually blue but often becoming rose-purple, or white; pedicels 1-1 1/2 in. long. May. Spain and Portugal. B.M. 1102. Gn. 78, p. 456; 79, p. 265.—Hardy. Several varieties of it are in the trade under the specific name *campanulata*, viz., *álba*, white; *albomajor*, large white; *cárnea*, flesh-colored; *hyacinthoides*, hyacinth-like; *rosea*, rose-colored. This species is worthy of wider acquaintance. The bulbs are cheap and easily obtained in autumn, and if planted then they are sure to bloom the following spring.

4. *numidica*, Poir. (*S. parviflora*, Desf.). Bulb ovoid, 1-2 in. thick: lvs. 4-6, fleshy, herbaceous, linear, 6-8 in. long, 1 1/2-3 lines broad, suberect: scape solitary or paired, 1/2-1 ft. high: racemes dense, 30-60-fl'd.: pedicels short, ascending, 3-5 lines long: bracts minute, linear, evanescent: perianth rose-purple, 1 1/2 lines long: single ovule in each of the ovarian cells: caps. small, globose, grooved. Flowering in winter in its native home, Algeria.

3575. *Scilla peruviana* in full bloom.—Also known as *Scilla ciliaris*. (X 1/4)

5. *chinensis*, Benth. (*Barnardia scilloides*, Lindl.). CHINESE SQUILL. Lvs. 2 or 3, equaling or exceeding the scape, rather hard, acute, channeled: bulb small, ovate: scape erect, slender, or wand-like: raceme spicate, dense, elongated: pedicels short; bracts whitish, minute: perianth rose-colored tipped with green; stigma a mere point. June. China. B.M. 3788.—Half-hardy. A beautiful species with the dense elongated raceme of rose-colored fls., worthy of cult. in any rock-garden.

6. *autumnalis*, Linn. AUTUMN SQUILL. STARRY HYACINTH. Lvs. several, obtuse, channeled, half-terete, growing on through the winter and dying away in the spring: scapes several: racemes corymbose, spicate, open: perianth rose-colored, 1/2 in. across. July-Sept. Eu. (Great Britain), N. Afr. B.M. 919.—Hardy. The flowering sts. generally precede the lvs. but occasionally the two come up together. As the flowering advances, in most cases a tuft of lvs. similar to those of *S. verna* shoot out by the side of the st. for the following year.

7. *peruviana*, Linn. (*S. ciliaris*, Hort. *S. Clusii*, Parl.). CUBAN LILY. PERUVIAN JACINTH. HYACINTH OF PERU (once thought to be a Peruvian plant). Fig. 3575. Bulb large, ovate, tunicate: lvs. many, broad-linear, 6-12 in. long; margins ciliated with minute white

bristles, channeled: scape robust, terminated by a many-fl. conic broad and compact raceme of purple, lilac, reddish, or whitish fls.: fls. rotate; corolla persistent; anthers short. May, June. Region of Medit., not Peru. B.M. 749. Gn. 27, p. 238. R.H. 1882, p. 508.—The hyacinth of Peru is not hardy in Mass. It propagates freely by offsets. It flowers all through May and

3576. *Scilla bifolia*. ($\times \frac{1}{4}$)

June and forms a most attractive object in the herbaceous border or bed. *S. peruviana*, however, has one fault that may tell against it in the opinion of many cultivators—it never flowers two years in succession; it seems to need a whole year's rest after the effort of producing its large spike of fls.

8. *monophylla*, Link (*S. monophylla*, Plan. *S. pumila*, Brot.). DWARF SQUILL. Lf. solitary, inclosing the base of the scape, 2 in. long, $\frac{1}{2}$ in. broad, involute, ovate-acuminate, with a callous apex, glabrous: scape erect, slender, usually 5–20-fl.: pedicels long, ascending, springing from a small sheathing bract: perianth bright lilac, $\frac{1}{2}$ in. across, open, spreading; filaments lilac-blue, dilated at base; anthers erect, blue. May. Spain, Portugal. B.M. 3023.—Hardy.

9. *bifolia*, Linn. Fig. 3576. Bulb tunicated, oblong-oval: lvs. 2, seldom 3, cucullate, 4–8 in. long, $\frac{1}{4}$ – $\frac{1}{2}$ in. broad: scape 2–8-fl., ebracteate: fls. stellately rotate; perianth blue, sometimes reddish or whitish; anthers blue, versatile. March. Eu., Asia Minor. B.M. 746.—Hardy. Several varieties of this exquisite little plant are in the trade: *alba*, white-fl.; *rosea*, pink-fl.; *ruberrima*, red-fl.; *splendens*, intense cobalt-blue fls. Cultivators would do well to obtain all the varieties possible; also as many bulbs of this beautiful species as they can afford. It is one of the most charming of hardy, early spring-flowering plants.

10. *natalensis*, Planch. Bulb thick, large, ovoid, subglobose: lvs. broadly lanceolate, glabrous, 9–12 in. long, 3–4 in. broad, ascending: scape erect, terete, 1–1 $\frac{1}{2}$ ft. long: raceme dense, simple, elongated, open, many-fl. (50–100): bracts solitary, subulate: fls. pale blue, stellate, rotate: pedicels long, pale blue. Natal. B.M. 5379. F.S. 10:1043.—Suitable for greenhouse cult. It is a graceful and elegant species, suitable for cult. in pots.

11. *hyacinthoides*, Linn. (*S. parviflora*, Salisb.). HYACINTH SQUILL. Lvs. 10–12, spreading, 1–1 $\frac{1}{2}$ ft. long, $\frac{1}{2}$ – $\frac{1}{4}$ in. broad, narrowed at both ends, minutely ciliate-denticulate on the margins: scape straight, long: racemes many-fl., broad, open: pedicels long, 1–1 $\frac{1}{2}$ in.: bracts whitish, minute, persistent; perianth bluish lilac, open, campanulate. Aug. Medit. region. B.M. 1140.—Hardy. This species is noted for its extreme shyness in flowering. The bulbs are sometimes 2 in. diam., and produce a profusion of offsets. In Fish's Bulb Culture several varieties are mentioned:

cærulea, fine blue; *alba*, fine white, free-flowering; *rosea*, distinct flesh-colored; *rubra*, deep red, large and fine.

12. *sibirica*, Andr. (*S. amœna* var. *præcox*, Don). SIBERIAN SQUILL. Fig. 3577. Lvs. 2–4, ascending, narrow, 4–6 in. long: scapes 1–6, 3–8 in. long: racemes 1–3-fl.; fls. rotate, horizontal or drooping, with short pedicels; perianth deep blue. March. Russia, Asia Minor. B.M. 1025. Gn. 11, p. 165. P.M. 14:100. L.B.C. 2:151.—Hardy. This plant ought always to have a little shelter. It forms attractive tufts and has a desirable habit for rock-gardens. Several trade forms exist, viz., *alba*, *multiflora*, *pallida*; *amœnula*, dwarfier with brighter blue fls.

13. *amœna*, Linn. STAR HYACINTH. Fig. 3578. Lvs. 4–7, flaccid, ascending, glabrous, 6–9 in. long, $\frac{1}{8}$ – $\frac{3}{4}$ in. broad: scapes several, equaling the lvs.: racemes several-fl., 4–8, open; fls. distant, $\frac{1}{2}$ – $\frac{3}{4}$ in. diam., blue: pedicels ascending or spreading. March. Austria, Germany. B.M. 341. G. 37:295.—Hardy. It grows luxuriantly, several flowering sts. being found on the same plant.

14. *italica*, Linn. ITALIAN SQUILL. Bulbs ovate, clustered together: lvs. radical, several, flaccid, spreading, lanceolate, acute, 4–8 in. long, $\frac{1}{4}$ – $\frac{1}{2}$ in. broad: scape solitary, slender, longer than the lvs.: raceme dense, many-fl.: pedicels filiform, spreading; bracts in pairs: fls. fragrant, smelling like lilac, pale blue; perianth rotate, blue; segms. puberulous at apex; filaments white; anthers sagittate, dark blue. March–May. B.M. 663. L.B.C. 15:1483.—Hardy. This plant has less brilliant fls. than either *S. sibirica* or *S. bifolia*, but abundantly compensates for the paleness of its blue by the fulness and the sweetness of its fragrance. It is also taller than either of the others.

15. *japonica*, Baker (*Ornithogalum japonicum*, Thunb. *Barnardia japonica*, Schult. f.). JAPANESE JACINTH. Bulb ovoid, 9–12 lines thick: lvs. 2–3, fleshy, herbaceous, 6–12 in. long, 4–16 lines broad, acute: scapes 1–3, strict, erect: raceme 20–60-fl.: pedicels

3577. *Scilla sibirica*. ($\times \frac{1}{4}$)

ascending: bracts minute, linear, white: perianth $1\frac{1}{2}$ lines long, rose-purple: caps. turbinate, trisulcate, $2\frac{1}{2}$ –3 lines long; ovules solitary in each ovarian locule. Japan.

16. *vérna*, Huds. SEA-ONION. SPRING SQUILL. A delicate little plant, with a small bulb and narrow-

linear lvs. 2-4 in. long; scape seldom 6 in. long, with several small, erect blue fls. in a short, terminal raceme, almost flattened into a corymb; perianth-segms. scarcely above 3 lines long, spreading. Spring. A plant occurring in stony and sandy wastes near the sea in W. Eu., as in Denmark, reappearing farther east on the Rhine and in Sardinia.—Hardy.

3578. *Scilla amoena*. ($\times \frac{1}{3}$)

S. axillaris, C. H. Wright. Of robust habit: lvs. 1 ft. long, $2\frac{1}{2}$ in. broad; raceme many-fl'd.; perianth-segms. white outside with green keel, bright violet edged with white inside. Hab. (?)—*S. cilicica*, Siehe. Bulb bluish violet; lvs. 4-8 in. long, about $\frac{1}{2}$ in. broad at apex; scape slightly taller than lvs.; pedicels one-half as long as fls.; fls. 2-6, bright blue, often tinged with violet; filaments white, thread-like. Asia Minor. G.C. III. 44:194, desc.

JOHN W. HARSBERGER.

SCINDÁPUS (an old Greek name, transferred to these plants). *Aracææ*. Climbing perennials, differing from *Monstera* in floral characters and in the long-petioled, long-sheathed, ovate-lanceolate, or ovate-acuminate lvs.—Species about 20 (Engler & Krause, *Pflanzenreich*, IV. 23B), E. Indies. *Scindapsus* comprises one popular and worthy warmhouse plant, that known to gardeners as *S. argyreaus*; also *S. aureus*, Engler (see *Pothos aureus*).

pictus, Hassk. Internodes of the st. 3-4 in. long, 2 in. thick; petioles $1\frac{1}{2}$ -2 in. long; blade 4-6 in. long, $2\frac{1}{2}$ - $3\frac{1}{4}$ in. wide, one side half as wide as the other, coriaceous, bright green (drying black), obliquely ovate-cordate. Var. *argyreaus*, Engler (*S. argyreaus*, Hort. *Pothos argyreaus*, Hort.), is the cult. form, with broad, deeply cordate lf.-blades which are spotted and blotched above with silvery white. Celebes, Philippines, Java.

S. anomalous, Hort.—*Monstera acuminata*.—*S. Cuscutaria*, Presl, is sometimes kept separate as *Cuscutaria marantifolia*. Not known to be in the trade. It is a question whether the *Aglaonema commutatum* sometimes mentioned in horticultural literature is this species or is properly referable to *Aglaonema*.—*S. pertusum*, Hort. = *Raphidophora pertusa*.

JARED G. SMITH.

SCÍRPUS (Latin for *bulrush*). **BULRUSH**. **SEDGE**. *Cyperacææ*. A large group of rush-like or grass-like plants inhabiting the whole globe. Flowers perfect, in spikelets, which are solitary, clustered or umbellate; scales spirally arranged; perianth of bristles or none, not enlarged in fr., smooth or barbed, persistent; ovary 1-loculed, with 1 anatropous ovule; style not thickened at the base, 2-3-cleft; fr. an achene with bristles attached. Only a few species are in cult., and these are all perennials (except perhaps the last), suited for shallow water or damp places. The larger are important for use in aquatic gardens. The nomenclature of those in the trade has been very much confused.

A. *Sts. leafy*.

atróvirens, Muhl. *Sts.* clustered, tall and stout, 2-4 ft. high, bluntly triangular; lvs. long, coarse, and firm,

3-6 lines wide, spreading; involucre foliaceous; umbel sparingly compound; rays stiff, very unequal; spikelets ovoid-oblong, acutish, dark greenish brown, in dense heads of 5-25; scales oblong, cuspidate; perianth-bristles 6, downwardly barbed above; styles 3. E. U. S. in mud or damp soil.

Holoschœnus, Linn. Stiff and rush-like, from stout rootstocks: sts. clustered, slender, cylindrical, 1-3 ft. high; lvs. 1-2, basal, stiff, erect and narrow, furrowed; bracts several, the larger one appearing as a continuation of the st.; spikelets very numerous and small, closely packed in 1 to several globular, light brown heads, 3-5 lines in diam.; scales ovate, mucronate, ciliate; perianth-bristles none; styles 2-3-cleft. Eu., Asia.—The form in cult is var. *variegatus*, Hort., with sts. alternately banded with green and yellowish white. Damp or dry soil.

AA. *Sts. with very short basal lvs. or none*.

B. *Rootstocks very stout, creeping; sts. scattered, 3-9 ft. high*.

lacustris, Vahl. **GREAT BULRUSH**. *Sts.* terete, smooth, tall, stout, and flexible, 3-9 ft. high; lvs. reduced to a few basal sheaths; bracts very short, erect; umbel compound, flexuous; spikes in heads of 1-5, oblong-conical, pale brown, $2\frac{1}{2}$ -8 lines long; scales ovate-oblong, obtuse, rarely mucronate; perianth-bristles 4-6, downwardly barbed throughout; styles 2-3. In shallow quiet water, N. Amer., Eu., Asia.—A composite species probably consisting in Eu. and Amer. of several distinct forms, each of specific rank. Typical *S. lacustris* is a 3-style form common in Eu., not found in Amer. *S. Tabernaemontanus*, Gmel., is a European 2-style form. The horticultural variety of the latter species, with alternate bands of green and yellowish white, is var. *zebrina*, Hort. (*Juncus zebrinus*, Hort.). *S. vallisidus*, Vahl, and *S. occidentalis*, Chase, are 2-styled American species. *S. heterochaetus*, Chase, is a 3-styled American form. The bulrush is very effective as a border plant in aquatic gardens.

3579.

Scirpus cernuus. Known to gardeners as *Isolopis gracilis*. ($\times \frac{1}{3}$)

BB. Rootstocks almost wanting: sts. cespitose, forming turf, 3-12 in. high, very slender.

cérnuus, Vahl (*S. gracilis*, Koch. *Isólepis gracilis*, Hort.). Fig. 3579. Sts. very slender or filiform, cylindrical, erect or more often drooping; basal sheaths leafless or with a very short filiform blade; involucre bract subulate, about equaling the spikelet, the latter usually solitary, oblong-lanceolate, 1-3 lines long; scales oblong-oval, obtuse, pale brown or whitish; bristles none; styles 3: achene in greenhouse plants rarely maturing. Widely distributed, common in Eu. G. 21:614; 25:111.—Grows well in damp pots, the drooping sts. producing a very graceful effect. This plant is now considered under *Scirpus* by practically all authors. *S. cernuus* is an older name than *S. gracilis*.

K. M. WIEGAND.

SLEROCÁRPUS (Greek, *hard* and *fruit*, the achenes are inclosed in a hardened palea). Syn., *Gymnópsis*, in part. *Compósitæ*. Annual or perennial strigose-pubescent herbs, suitable for outdoor planting in the S.: sts. branching; lvs. alternate or the lower rarely all opposite, dentate or subentire: heads small or medium, at the ends of the branches, pedunculate, many-flid.: fls. yellow; the ray-fls. few to several, fertile; pappus wanting: achenes more or less 4-sided with a broad flat summit.—About 15 species. N. Amer., region of Texas and Mex., Trop. Afr., and Trop. Asia. *S. uniseriatis*, Benth. & Hook. f. (*Gymnópsis uniseriatis*, Hook. *Gymnoldmia uniseriatis*, Hort.). Annual, 1-2 ft. high, loosely branched: lvs. alternate, slender-petioled, deltoid- or rhombic-ovate, or the uppermost lanceolate, coarsely dentate, the strigose pubescence of the lower surface canescent; corollas orange. Texas and Mex. R. H. 1853:261. G. C. III. 28:165.

SLEROCÁRYA (Greek, *hard* and *nut* or *kernel*). *Anacardiaceæ*. Trees or shrubs, one of which, *S. caffra*, has been intro. into S. Calif.: lvs. aggregated toward the ends of the branches, alternate, odd-pinnate, glabrous; lfts. opposite, long-petiolate, very entire, glaucous below: the male fls. spicate; fls. polygamous; sepals 4, orbicular, colored, imbricate; petals 4, oblong, obtuse, spreading, reflexed, imbricate; disk depressed, entire; stamens in the male fls. 12-15, in the female fewer; ovary subglobose, 2-3-celled: drupe somewhat fleshy, the shell woody, 2-3-celled.—About 5 species, Trop. and S. Afr. *S. caffra*, Sond. Glabrous: lvs. alternate, 6-12 in. long; lfts. $1\frac{1}{2}$ -2 in. long, with a short, often oblique tapering point, base acute, pale below: male spikes 2-4, terminal: fls. very short-pedicelled, bracteolate, the dried pedicel red: drupe suborbicular, the size of a small walnut. S. Afr.

SCOLOPÉNDRIUM (from *Scelopendra*, the name of a centiped, the resemblance being found in the lines of linear sori on the backs of the lvs.). *Polypodiaceæ*. The name most common in the trade for the hart's-tongue ferns (known as *Scolopendrium vulgare*) and its varieties. See *Phyllitis*.

SCOLÒPIA (Greek, *thorn* or *stake*, probably so named on account of the spines). *Flacourtiaceæ*. Spiny trees, the spines often compound, one of which, *S. crenata*, has been intro. in S. Calif.: lvs. alternate, entire; stipules minute or none: fls. small, racemed, axillary, dioecious; sepals 4-6; petals 4-6, subsimilar; stamens many; ovary 1-celled: berry 2-4-seeded.—About 30 species, Afr., Asia, and Austral.

crenata, Clos. Branches of young trees armed, of old unarmed: lvs. 2-6 x 1-2 in., ovate or oblong-lanceolate, base acute, obtusely or acutely acuminate, subcrenate, glabrous: racemes axillary, 1-3 in. long: sepals and petals 5-6 each: fr. globose, green, when dry the size of a cherry. India, China, and the Philippines.—Intro. into Calif.

SCÓLYMUS (old Greek name used by Hesiod). *Compósitæ*. Three or four herbs, all natives of the Mediterranean region. *S. grandiflorus*, a perennial species, is rarely cultivated abroad for its flowers and *S. maculatus*, an annual species, for its variegated foliage.

Scolymus hispanicus (Fig. 3580) is the vegetable known as golden thistle or Spanish oyster plant. It makes a root very like salsify, except that it is much lighter colored and considerably longer. Its flavor is less pronounced than that of salsify, but when carefully cooked, it possesses a very agreeable quality which is somewhat intermediate between that of salsify and parsnip. It is adapted to all the methods of cooking employed for those vegetables. The particular value of

the Spanish oyster plant, aside from affording a variety in the kitchen-garden, is its large size and productiveness as compared with salsify. The product may be nearly twice as great, for a given area, as for salsify. The seeds are much easier to handle and to sow than those of salsify. They are sown in March or April. The seeds, or rather achenes, are flat and yellowish, surrounded by a white scarious margin. The roots may be dug either in fall or spring. The greatest fault of the Spanish oyster plant lies in the prickly character of the leaves, which makes the plant uncomfortable to handle. The roots are often 10 to 12 inches long and 1 inch thick. It is said that the leaves and stalks are eaten like cardoons by the people of Salamanca; also that the flowers are used to adulterate saffron.

3580. Spanish salsify, or golden thistle.—*Scolymus hispanicus*.

The *S. hispanicus*, Linn., is a biennial plant, native to S. Eu. The radical lvs. are very spiny, oblong, pinatifid, dark green, marked with pale green spots. The plant grows 2-2½ ft. high, is much branched and bears bright yellow fl.-heads which are sessile and contain only 2 or 3 fls., all of which are ligulate. The heads are sessile, terminal, and axillary. L. H. B.

SCOPÒLIA (named in honor of Joh. Ant. Scopoli, 1725-1788). *Solanaceæ*. Erect slightly branched glabrous hardy perennial herbs for outdoor planting: lvs. membranaceous, entire: fls. lurid purple or greenish, veined, nodding, borne on solitary filiform pedicels; calyx broad-campanulate, membranaceous truncately or broadly 5-lobed; corolla campanulate, the limb folded, 5-angled or shortly and broadly 5-lobed; stamens 5; ovary conical, 2-celled almost to the apex: caps. included in the calyx.—About 5 species, 1 in Eu., 1 in Himalaya, and the others in Japan and China. *S. carnifolia*, Jacq. (*Hyoscyamus Scopolia*, Linn.). About 1 ft. or more high: lvs. entire, petiolate, about 3 in. long, ovate or obovate-oblong, subcuspidate: fls. solitary, axillary, nodding; corolla lurid red, yellow, or green inside. Russia. B. M. 1126.—Somewhat used in medicine.

SCORODÓSMA: *Ferula*; supplementary list.

SCORPIURUS (Greek, *scorpion* and *tail*, alluding to the twisted form of the legume). *Leguminosæ*. Nearly hardy stemless or decumbent herbs, adapted to the open border: lvs. simple, very entire, elongate, twisted and folded; stipules adnate to the petiole; fls. yellow, often few, solitary or umbelled, on axillary peduncles; nodding; calyx with the 2 upper lobes connate above; petals long-clawed, the standard suborbiculate, the wings oblique-obovate or oblong, the keel incurved, beaked-acuminate; stamens free from the standard; ovary sessile, many-ovuled: legume subterete, circinate-involute, sulcate-costate, the ribs often tuberculate or muricate, indehiscent.—About 6 species, S. Eu., N. Afr. to the Canary Isls., and W. Asia. Prop. by seed sown in the open border in the spring. *S. vermiculata*, Linn. A trailing annual: lvs. tapering into the petioles: fls. solitary on the peduncles, the standard streaked with red: pod thick, glabrous, with the inner ribs almost obsolete, but the 10 outer ones bear crowded stipitate tubercles which are obtusely dilated at the apex. Medit. region. See the article *Worms*.

SCORZONÈRA (old French *scorzon*, serpent; *S. hispánica* was used against snake-bites). *Compósitæ*. The vegetable known as scorzonera or black salsify is a plant with a long fleshy tap-root like that of salsify, but differing in having a black skin. The flesh, however, is white. It is cultivated and cooked like salsify, but being somewhat more difficult to raise it is rarer than that vegetable, although considered by many to be superior to it in flavor. The leaves may be used for salads. Scorzonera is a perennial plant, but it is treated in cultivation as an annual or biennial crop.

Perennial herbs, or rarely annual, floccose, lanate or hirsute: lvs. sometimes entire and grass-like, or wider, sometimes more or less pinnately lobed or dissected: heads long-peduncled, yellow, the fls. all radiate: achenes glabrous or villous.—Over 100 species, all natives of the Old World. Cult. same as salsify.

Botanically, also, Scorzonera is closely allied to salsify. The two vegetables are easily distinguished in root, leaf, flower, and seed. The leaves of Scorzonera are broader, the flowers are yellow (those of salsify being violet), and the seeds are white. Also, the involucre bracts of Scorzonera are in many series; of salsify, in one series.

hispánica, Linn. **SCORZONERA. BLACK SALSIFY.** Perennial herb, 2 ft. high: st. much branched: lvs. clasping, lanceolate, or in some forms linear, undulate, glabrous: heads solitary at the ends of the many branches of the infl. Cent. Eu. **WILHELM MILLER.**

SCOTCH BROOM: *Cytisus scoparius*. S. Pine: *Pinus sylvestris*.

SCOURING-RUSH: *Equisetum*.

SCREW BEAN: *Prosopis*. S. Pine: *Pandanus*.

SCROPHULARIA (a reputed remedy for scrofula). *Scrophulariæ*. **FIGWORT.** Herbs or subshrubs, glabrous or hirsute, often fetid, sparingly grown in the herbaceous border.

Leaves opposite or the upper alternate, entire, incised, or dissected: cymes lax, in a terminal simple or somewhat branched thyrsus: fls. small, rarely rather large, greenish purple, purple, lurid or yellow; calyx deeply 5-cleft or 5-parted; corolla 5-lobed, short, 4 erect, the anterior one spreading; stamens 4, perfect, didynamous: caps. ovoid or subglobose.—About 150 species, Medit. region, Orient and N. Amer.

aquática, Linn. A tall glabrous plant: sts. very acute-angled or winged: lvs. ovate-oblong, rather obtuse, base cordate; the petioles winged: thyrses elongated, often 1–2 ft. long, the cymes peduncled, laxly many-flid.: calyx-segms. orbiculate. Eu. and Caucasus. Var. *variegata*, Hort., the lvs. have a broad white marginal band.

marilândica, Linn. (*S. nodosa* var. *marilândica*, Gray). A tall-growing hardy perennial herb, usually 5 ft. high, often more, with large, dark green, ovate-acuminate lvs. and small, dull purplish or greenish fls. in a nearly naked, open thyrses. Throughout the U. S.—The plant is sometimes used as a foliage background for the herbaceous border. It is too inconspicuous in fl. and too weedy in habit for general use.

F. TRACY HUBBARD.†

SCURVY-GRASS (*Cochlearia officinalis*, Linn.), a common European perennial, is so called from its antiscorbutic qualities which have long been recognized. Stimulant, diuretic, stomachic, and laxative properties have been ascribed to it. In general appearance—leaf, flower, and fruit—it somewhat resembles its close relative, water-cress, but in flavor it is acrid, bitter, pungent, and has a strong suggestion of tar. Bruising reveals a disagreeable odor. When cultivated it is treated as an annual, the seed being sown on garden loam in a cool, shady place where the plants are to remain. It is grown to a limited extent in America, has escaped from cultivation, but so far has not become obnoxious as a weed like water-cress and horse-radish. Consult Vol. II, p. 808, for botanical description. M. G. KAINS.

SCUTELLARIA (Latin, *dish*; referring to the form of the persistent calyx). *Labiâtæ*. **SKULLCAP.** Annual or perennial herbs, or decumbent or diffuse rarely tall and erect subshrubs or very rarely shrubs, suitable for outdoor planting.

Leaves opposite, frequently dentate, sometimes pinnatifid or entire; the floral lvs. similar or changed into bracts: fls. in opposite 2-flid. floral whorls or in some species a few at the top, sometimes disposed in all or the lower axils, sometimes in terminal racemes or spikes, blue, violet, scarlet, or yellow; calyx campanulate, 2-lipped; corolla-tube long-exserted, limb 2-lipped; stamens 4, ascending, all fertile, the anterior pair longer: nutlets subglobose or depressed.—About 140 species scattered over the world, mostly in the temperate regions and the mountains, a few in Trop. Afr., not known from S. Afr.

KEY TO THE SECTIONS.

- A. *Floral lvs. membranaceous: fls. 4-angled-spicate or subracemose, scarcely secund.*
 - Section I. LUPULINARIA. Species 1, 2.
- AA. *Floral lvs. herbaceous: fls. secund.*
 - B. *Fls. not opposite, all or at least the uppermost remote.* Section II. HETERANTHESIA. Species 3.
 - BB. *Fls. opposite.*
 - c. *Infl. composed of fls. in terminal single or panicled racemes. (The delimitations between this and the following section are not well marked.)*
 - Section III. STACHYMACRIS. Species 4–11.
 - CC. *Infl. composed of fls. solitary in the axils or in axillary and terminal racemes.*
 - Section IV. GALERICULARIA. Species 12–18.

Section I. LUPULINARIA.

All Old-World species.

- A. *Lvs. green on both surfaces or hardly crenate*..... 1. *alpina*
- AA. *Lvs. hoary beneath, incise-dentate or pinnatifid*..... 2. *orientalis*

1. *alpina*, Linn. A hardy spreading perennial, about 10 in. high, with ovate, serrately dentate lvs. and large, purple and white or somewhat yellowish fls. in dense, terminal racemes. July, Aug. Eu. R.H. 1889:12.—A handsome rock or low border perennial. Var. *álba*, Hort., a white-fl. form offered in the trade. Var. *cærulea*, Hort., is offered in the trade. Var. *lupulina*, Benth. (*S. lupulina*, Linn. *S. lupulina bicolor*, Hort.), is a form with yellow fls. Var. *rôsea*, Hort., is offered in the trade.

2. *orientâlis*, Linn. (*S. grandiflora*, Sims, not Adams. *S. pulchella*, Bunge). A hardy perennial, procumbent: lvs. long-petioled, ovate, dentate, tomentose: fls. purplish, with a yellow throat or almost entirely yellow. Altai Mts. B.M. 635.

Section II. HETERANTHESIA.

All American species.

3. *Ventenâti*, Hook. Perennial: sts. erect, branched, everywhere soft-slender-pubescent: lvs. long-petioled, rather thick, cordate-ovate, rather obtuse, coarsely serrate: racemes terminal, elongated, subsecund or subdistichous: calyx small; corolla scarlet, about 1 in. long, the upper lip deeply 4-cut. Colombia. B.M. 4271. G.C. III. 35:376.

Section III. STACHYMACRIS.

- A. Lvs. subsessile or short-petioled, subentire, lanceolate or linear..... 11. *baicalensis*
- AA. Lvs. petioled, crenate or serrate, ovate to subrotundate.
- B. Base of the lvs. narrowed, blades usually ovate-oblong or oblong-lanceolate.
- C. Margins serrate..... 9. *montana*
- CC. Margins entire..... 10. *brevifolia*
- BB. Base of at least some of the lvs. truncate or cordate.
- C. Floral lvs. sessile or shorter than the calyx.
- D. Sts. procumbent or low, scarcely 1 ft. high.
- E. Surface of lf. villous above and below: lvs. small, subrotundate..... 4. *indica*
- EE. Surface of lf. hispidulous above: lvs. ovate..... 5. *violacea*
- DD. Sts. erect, more than 1 ft. high..... 6. *altissima*
- CC. Floral lvs. petiolate, equaling or exceeding the calyx.
- D. Corolla purple to violet..... 7. *peregrina*
- DD. Corolla white..... 8. *albida*

4. *indica*, Linn. St. procumbent at base: branches ascending, 6 in. to 1 ft. high: lvs. small, petiolate, rotundate, crenate, base cordate, both surfaces minutely pubescent: raceme dense, subsimple, 3-4 in. long: fls. opposite, secund; calyx pubescent; corolla bluish, rather glabrous, the lower lip very broad. China and Japan. Var. *japonica*, Hort. (*S. japonica*, Morr. & Deene.), grows about 6 in. high: lvs. ovate, gray-green: fls. blue or lilac; corolla pubescent. Japan. P.M. 10: 123. F.S. 2:80. H.U. 5, p. 105. G.M. 57:791.

5. *violacea*, Heyne. Herb. 6-12 in. high: st. erect or ascending, pubescent: lvs. petioled, cordate-ovate, 1-3 in. long, crenate, pubescent or glabrous beneath: racemes 4-5 in. long, lax, subsimple: fls. opposite, secund; calyx pubescent; corolla $\frac{1}{2}$ in. diam., violet. India and Ceylon. B.M. 8320. G.W. 14, p. 620.

6. *altissima*, Linn. St. erect, branched: lvs. petioled, ovate or ovate-lanceolate, crenate, base broad-cordate, scarcely rugose: racemes elongated, somewhat branched, villous: fls. opposite, secund; calyx villous; corolla creamy yellow, 4 times as long as the calyx. S. E. Eu. and Caucasus.

7. *peregrina*, Linn. Sts. procumbent: branches elongated, glabrous or pubescent near the ends: lvs. petioled, ovate, obtuse, crenate, base rotund-truncate,

glabrous or slightly pubescent: racemes elongated, lax: fls. subsessile, opposite, secund; calyx large, somewhat pilose; corolla violet, pubescent outside. S. Eu. and the Orient.—The sts. and lvs. are frequently glabrous and dark purplish or reddish.

8. *albida*, Linn. Branches elongated, pubescent: lvs. $1\frac{1}{2}$ in. long, petioled, broad-ovate, coarsely crenate, base rotundate-truncate or the lowest cordate: racemes often more than 1 ft. long, lax: fls. opposite, secund, subsessile; calyx pilose; corolla $\frac{1}{2}$ in. long, dirty white, villous outside. S. E. Eu. and Cent. Asia.

9. *montana*, Chapm. Perennial, tomentose-pubescent: st. simple, erect, 1-1 $\frac{1}{2}$ ft. high: lvs. ovate or oblong-ovate, coarsely and sharply serrate, lowest subcordate, upper acute at both ends, petioled: raceme simple, few-fl. fls. opposite; corolla large, $1\frac{1}{4}$ -1 $\frac{1}{2}$ in. long, blue. Mountains of Ga.

10. *brevifolia*, Gray. A half-hardy, compact perennial, $\frac{1}{2}$ -1 ft. high: lvs. numerous, oblong, narrow, about $\frac{1}{2}$ in. long: fls. dark purple, about $\frac{3}{4}$ in. long. Blooming season long; summer. Dry limestone banks, Texas.

Subsection ANGUSTIFOLÆ.

11. *baicalensis*, Georgi (*S. macrantha*, Fisch.). A hardy perennial herb, almost glabrous: st. half erect, about 1 ft. high: lvs. lanceolate, obtuse, ciliate: fls. blue, in many simple racemes; calyx-hood incurved. July, Aug. E. Asia. Var. *cœlestina*, Hort., has large spikes of bright blue fls. July. G.W. 9, p. 61.

Section IV. GALERICULARIA.

- A. Fls. scarlet or red, irregularly arranged in axillary and terminal racemes: lax herbs or shrubs..... 18. *Mociniana*
- AA. Fls. blue or violet.
- B. Infl. composed of axillary racemes: lax, strongly branched herbs..... 17. *lateriflora*
- BB. Infl. composed of solitary axillary fls. or the uppermost fls. subracemose.
- C. Margins of lvs., at least the lower, crenate or dentate or the base hastate..... 13. *galericulata*
- CC. Margins of lvs. all entire.
- D. Blades oblong-lanceolate or linear..... 12. *angustifolia*
- DD. Blades ovate
- E. Lvs. petiolate, remote..... 16. *antirrhinoides*
- EE. Lvs. subsessile, approximate.
- F. Plants without moniliform tubers..... 14. *resinosa*
- FF. Plants with moniliform tubers..... 15. *Brittonii*

Subsection GENUINÆ.

12. *angustifolia*, Pursh. A hardy perennial, about 6 in. high, with lvs. $\frac{1}{2}$ -1 in. long, narrowed at the base, and violet-blue fls. $\frac{3}{4}$ -1 in. long, with the corolla-tube slender. Moist ground, N. W. U. S.

13. *galericulata*, Linn. Hardy, perennial by filiform stolons, 1-3 ft. high: lvs. ovate to oblong-lanceolate, about 2 in. long: fls. solitary in the axils of the upper lvs., about 1 in. long. June-Sept. In moist ground throughout the U. S. and Eu. B.B. 3:83; (ed. 2) 3:109.

14. *resinosa*, Torr. (*S. Wrightii*, Gray). Plants minutely glandular-pubescent: sts. herbaceous, low, erect and much-branched: lvs. about $\frac{1}{2}$ in. long, ovate or spatulate-oblong, very obtuse, both surfaces green, entire, base rotundate or subcuneate not cordate, resinous-glandular: fls. axillary, opposite, secund; calyx glandular-pubescent; corolla blue, densely villous. Kans. to Texas and westward to Ariz. B.B. (ed. 2) 3:108.

15. *Brittonii*, Porter. Glandular- or viscid-pubescent, branching from the base, 4-8 in. high: lvs. oblong or oval, sessile and entire or the lowest short-petioled and slightly crenulate: fls. solitary in the axils; corolla blue

(pale blue and white according to some). Wyo. and Colo., and probably W. Neb. B.B. (ed. 2) 3:108.—Allied to *S. resinosa*.

16. *atirrhinoides*, Benth. Resembles the larger-leaved forms of *S. angustifolia*, but has longer petioles and the lvs. mostly obtuse at base and also shorter and broader fls. 7–10 lines long. Shady ground, N. W. U. S.

Subsection LATERIFLORÆ.

17. *lateriflora*, Linn. A hardy perennial, increasing by slender stolons, 1–2 ft. high: lvs. ovate to lanceolate, 1–3 in. long: racemes axillary or terminal, narrow, leafy bracted: fls. blue to nearly white. Moist soil throughout the U. S. B.B. (ed. 2) 3:106.

Subsection PTERILOMTOIDEÆ.

18. *Mociniæna*, Benth. A tender, moderately low, shrubby plant, probably the most showy of the genus, with opposite, long-elliptical, acute lvs., and long, tubular, red fls. with a yellow throat, about 1½ in. long, in dense, terminal spikes. Autumn. Mex. R.H. 1872:350. G.W. 11, p. 127. G.Z. 13:2.—According to Gn. 10, p. 606, the plants are of easy cult. with warm greenhouse treatment and may be grown as bush specimens or in smaller pots with a single st., when they will flower at about 1 ft. in height. Cuttings are easily rooted.

S. aurantiaca, Hort., is offered in the trade.—*S. pulchella*, Hort., not Bunge, belongs to Section III and is closely related to *S. indica* var. *japonica*, but the plant has more slender twigs, somewhat smaller lvs. which are short stiff-hairy on the upper surface and a looser raceme with somewhat darker blue fls. Hab. (?). Gt. 6:296.—*S. splendens*, Link, Klotzsch & Otto, belongs to Section II and has broad ovate, obtuse or scarcely acuminate, crenate lvs., with the base cordate and both surfaces hirsute: raceme elongated: fls. sparse; corolla scarlet. Mex. B.M. 4290 (as *S. cordifolia*).

F. TRACY HUBBARD†

SCUTICARIA (Latin, *scutica*, lash or whip). *Orchidaceæ*. Orchids remarkable for their long whip-like leaves, which are channeled on one side.

No evident pseudobulbs formed, but each shoot terminating in a long, pendulous lf.: lvs. rather crowded on the short rhizome: fls. solitary or several, on short peduncles, in structure fls. resembling *Maxillaria*, but the plants are easily distinguished by the terete lvs.; sepals and petals similar, the lateral ones forming a mentum; labellum movable, 3-lobed, with large, erect, lateral lobes; pollinia on a transversely elongated stipe.—Two species from S. Amer.

These plants require a temperature similar to *cattleya* and *lælia*, but should be grown on blocks or in shallow baskets in a mixture of equal parts peat fiber and sphagnum. *S. Steelii* does best on a block, as the plant grows downward in an inverted position. The compost should be kept moist, particularly while the plants are in action. They are propagated by division. (R. M. Grey.)

Steelii, Lindl. Fig. 3581. Lvs. attain a length of 4 ft., as thick as a goose-quill: fls. on short scapes; sepals and petals oblong, connivent, pale yellow, with chocolate blotches; labellum large, cream-colored, striped with brownish purple, at all seasons. British Guiana. B.M. 3573. B.R. 1986 (both as *Maxillaria Steelii*).

3581. *Scuticaria Steelii*.

Hádwenii, Planch. Lvs. 1½ ft. long: fls. with spreading sepals and petals oblong, sharply acuminate, yellowish green, blotched with brown; labellum obovate-cucullate, white with flesh-colored spots. Brazil. B.M. 4629. F.S. 7:731 (both as *Bifrenaria Hadwenii*). G.M. 41:558.

HEINRICH HASSELBRING.

SCYPHÁNTHUS (Greek, *beaker* and *flower*, alluding to the shape of the flower). Syn., *Grammatocarpus*. *Loasaceæ*. Climbing pubescent half-hardy annual herbs for outdoor border planting: lvs. opposite, 2–3-pinnatisect: fls. axillary, sessile, yellow; calyx-tube linear-elongate, lobes 5, spreading, linear-spatulate; petals 5, saccate, alternate, with smaller scales which are hooded, 3-aristate and at base have 2 calli; stamens very many, in 5 fascicles opposite the petals, staminodia 10, in pairs opposite the scales; ovary elongated, 1-celled: caps. linear, upright, longitudinally 3-valved.—One or 2 species, Chile.

élegans, Don (*Grammatocarpus volubilis*, Presl). Sts. herbaceous, climbing and twining, frequently branched: lvs. opposite, rough with minute deflexed hairs, the lower ones bipinnatifid, the upper ones smaller and only pinnatifid, all the segms. oblong, 1-nerved; petiole short, channeled: fls. really sessile but appearing peduncled from the elongated inferior ovary, terminal or axillary, yellow, calyx-tube very long and incorporated with the ovary, limb of 5 spreading, spatulate, leafy segms.; petals 5, forming a cup, obovate-spatulate, deeply saccate below the middle. B.M. 5028. J.H. III. 44:272.

F. TRACY HUBBARD.

SEAFÓRTHIA (Francis Lord Seaforth, patron of botany). *Palmææ*. A genus of palms, founded by Robert Brown on an Australian species, usually considered as synonymous with *Ptychosperma*. The *Seaforthia elegans* of cultivation, however, is said to be *Archontophoenix*, mostly *A. Cunninghamii* and perhaps some of it *A. Alexandræ*; the original species described by Brown as *S. elegans* becomes *Ptychosperma elegans*, Blume.

According to Dammer (G.C. III. 31, pp. 18–20) the true *Ptychosperma elegans* of Blume is met with but rarely in European gardens. What is cultivated under this name in most cases is either *Archontophoenix Cunninghamii* or *A. Alexandræ*. These archontophoenixes "are decorative hardy palms, forming on the Riviera very fine high-stemmed specimens. In youth they form bifid leaves, the blade almost horizontal. After having made some four to six such leaves, each larger than the foregoing, there appears a fully pinnate leaf, much differing in mode of growth from *Phoenix* and other pinnatisect-leaved palms." *Seaforthia elegans*, Hort., and *Ptychosperma elegans*, Hort., are apparently sometimes *Archontophoenix Cunninghamii* and sometimes *A. Alexandræ*. The last is very like *A. Cunninghamii*, but, according to Dammer, differs in its segments, which are green only above while underneath they are ashy-glaucous or white; it is well figured in G.C. III. 31:19; also in B.M. 4961 as *Seaforthia elegans*. *A. Cunninghamii* is figured in B.M. 7345 as *Ptychosperma elegans*. The true *Ptychosperma elegans*, Blume (*Seaforthia elegans*, R. Br., not Hort.), with pinnules erose rather than acuminate at apex, is figured in G.C. III. 31:21.

In a recent study, O. F. Cook separates the plant grown in California under the name of *Seaforthia elegans* into a new genus, *Loroma*, making the species *L. amethystina*; probably from Australia. He also retains the genus *Seaforthia* for *S. elegans*, R. Br.

SEA-KALE (*Crambe maritima*, Linn.) is a large-leaved strong cruciferous perennial, the young shoots of which are eaten in the spring, usually after having been blanched. The plant is little known in North America, but it is worthy of general cultivation in the home-garden, for it supplies an esculent of good quality

at a season when vegetables are scarce. Sea-kale demands a deep rich and rather moist soil, in order to give the best results and to maintain its vigor for a series of years. The plants require about as much room as rhubarb; that is, they should stand from 3 to 4 feet apart each way. The culture and general requirements are much the same as for rhubarb. The young shoots are blanched as they grow, in early spring. The blanching is accomplished by heaping fine loose earth over the crown of the plant, into which the shoots grow, or by covering the plant with an inverted box or flower-pot so that the light is excluded from the growing shoots. These shoots are eaten before the leaves have begun to expand to any extent, whilst crisp and tender. The vegetable is prepared as is asparagus.

Sea-kale is propagated by root-cuttings, and also by seeds. Quicker results are secured from cuttings. If strong cuttings, 4 or 5 inches long, are taken in early spring and grown in good and rather moist soil, the plants may be strong enough for cutting the following spring; but it is usually better not to cut them until two years from starting. The cuttings may be placed where the plants are to stand permanently, or they may be grown in drills in a seed-bed. The latter plan is usually to be preferred, since it allows the plants to receive better care. Seeds give plants that are strong enough for cutting about the third year. The seeds are really fruits or pods, and each fruit may produce two or three plants. Usually the fruits are sown without shelling. The seedlings are raised in the seed-bed and transplanted when one year old to permanent quarters. On good soil, plants of sea-kale should maintain their vigor for five to eight years after they have come to cutting age. As soon as they begin to show signs of decline, new plants should be propagated. Although the plant is hardy in the northern states, it is always benefited by a liberal dressing of litter or manure in the fall. Plants may be forced in hotbeds or under the greenhouse benches, as recommended for rhubarb. Sea-kale has large glaucous cabbage-like leaves which make it a striking plant for ornament early in the season. It also throws up a strong cluster bearing many rather showy white flowers. However, the plant is rarely propagated for its ornamental value. For botanical description, see Vol. II, p. 873.

L. H. B.

SEA-LAVENDER: *Statice*. S.-onion: *Urginea maritima*; also applied to *Ornithogalum caudatum* and *Scilla verna*. S. pink: *Armeria*.

SEBASTIÂNIA (from Antonio Sebastiani, a writer on Roman plants 100 years ago). *Euphorbiaceæ*. Tropical shrubs scarcely in cult.: juice milky; lvs. alternate, small, usually entire; infl. usually terminal: fls. apetalous; staminate calyx with 2-3 sepals free or connate at the base, imbricate; stamens 1-5; ovules 1 in each cell of the ovary; seed carunculate. About 75 very variable species, all tropical except *S. ligustrina*, Muell. Arg., in swamps from N. C. to Fla. *S. Palmeri*, Rose, has very poisonous juice and the seeds are among the best known of the "Mexican jumping beans" which are inhabited by a small lepidopterous larva whose actions cause the springing motions of the seeds.

J. B. S. NORTON.

SECÂLE (the ancient Latin name, said to be derived from *seco*, to cut; according to some applied to spelt). *Gramineæ*. Spikelets with 2 perfect fls., sessile on opposite sides of a zigzag rachis, forming a terminal spike; glumes subulate, 1-nerved; lemmas keeled, long-awned.—Species 2, *S. fragile*, an annual of S. Russia, and *S. cereale*, the cult. rye, which, according to Hackel, is derived from a wild perennial form (*S. montanum*, Guss.), native in mountains, S. Eu. and Cent. Asia.

cereâle, Linn. **RYE**. Tall annual, commonly cult. in Eu., less so in U. S., as a cereal. Also cult. here for annual pasture. Dept. Agric., Div. Agrost., Bull. 20:163.

A. S. HITCHCOCK.

SÈCHIUM (probably from the Greek *sekos*, "to fatten in a fold," because it was fed to hogs). *Cucurbitaceæ*. A climbing sparsely hairy herb, with perennial tuberous roots, grown in tropical and subtropical regions for its large fruits, which somewhat resemble the summer squash in use and character.

Leaves membranaceous, 3-angled or -lobed, cordate at the base; tendrils 2-5-branched, opposite the lvs.: fls. small, monœcious, axillary, the pistillate solitary, the staminate in small clusters; calyx-tube saucer-shaped, the limb 5-lobed; corolla rotate, deeply 5-parted, the segms. ovate-lanceolate; filaments and styles connate into a central column, of which the anthers appear as lobes, while the stigmas are closely set together, forming a small head: fr. pear-shaped or globose, fleshy, 1-seeded.—One species, indigenous in Mex. and Cent. Amer. and widely planted.

edûle, Swartz (*Chayote edulis*, Jacq.). **CHAYOTE**. **CHAYOTLI**. **CHOUCHOUTE**. **CHOCO**, **CHUCHU**, or **XUXU**. **CHOKO**. **CHAIOTA**. **MIRLITON**. **CHRISTOPHINE**. **PIPINELLA**. Fig. 3582. Sts. herbaceous, annual, sometimes making a growth of 50 ft. in one season, if the

3582. Fruit of *Sechium edule*. (×½)

plant is grown on rich well-drained ground: large tuberous roots are formed the second season: lvs. 4-6 in. long, resembling those of the cucumber, deep green, somewhat rough, scarcely hairy; corolla greenish or cream-colored: fr. 3-8 in. long; seed single, flat, 1-2 in. long, attached at the upper end of the cavity. G.C. 1865:51; III. 24:476; 28:450.

The chayote is grown successfully in southern California and about New Orleans, where it is fairly common. In Florida it is not yet common, but its culture is being extended rapidly. It can probably be grown successfully in those parts of the South where the ground does not freeze in winter. The fruit is round to pear-shaped, smooth or corrugated, the surface sometimes covered with small soft spines. The color varies from nearly white to dark green, the flesh being firm, crisp, and more delicately flavored than the squash. The cooked fruit can be creamed, baked, or made into fritters, sauces, tarts, puddings, salads, or used like potatoes with other meats and vegetables. The young spring shoots, tender branches, and tuberous roots form palatable dishes, while the woody stems furnish a fine fiber, known in French as "paille de chouchou." The fruits, vines, and tubers are excellent fodder for stock.

The entire fruit is planted in early spring, and the vine should come into fruit after the rainy season, remaining in fruit (in the southern United States) until the plant is cut down by frost. Plants should be 8 to 10 feet apart, and trained on an arbor or trellis. In

Florida and the Carolinas, a vine may yield fifty to one hundred or more fruits in a season. The fruit can easily be shipped, and stored for two to four months at moderate temperatures. In tropical and subtropical regions there are numerous varieties, differing somewhat in flavor and value.

NATHAN MENDERSON.

SECURINÈGA (Latin, *securis*, hatchet, and *negare*, to refuse, alluding to the hard wood). *Euphorbiaceæ*. Shrubs sometimes grown for the bright green foliage.

Deciduous: lvs. alternate, short-petioled, entire, stipulate; fls. dioecious or monocious, apetalous, axillary; the pistillate solitary or few, the staminate in fascicles; sepals 5; stamens usually 5, with a 5-lobed disk at the base; pistillate fls. with entire disk; ovary 3-celled, with 3 2-lobed styles; fr. a 3-lobed dehiscent caps., 3-6-seeded.—About 10 species in temperate and subtropical regions of S. and Cent. Amer., Asia, Afr., and S. Eu.

The species in cultivation are bushy round shrubs with slender wand-like branches, rather small bright green foliage, inconspicuous greenish white flowers in axillary clusters or solitary and with small subglobose greenish capsules. They have proved fairly hardy at the Arnold Arboretum, usually only the tips of the young branchlets being winter-killed, and do not seem particular as to the soil. Propagation is by seeds which are usually freely produced when the two sexes are present, and by greenwood cuttings under glass.

ramiflora, Muell. Arg. (*Géblera suffruticosa*, Fisch. & Mey. *Flüggea suffruticosa*, Baill. *Acideton ramiflorus*, Kuntze). Shrub, 3-6 ft. high, with greenish branchlets: lvs. short-petioled, oval or ovate to ovate-lanceolate, acute or obtuse, cuneate at the base, entire, bright or yellowish green, glabrous, thin, 1-2 in. long: staminate fls. about 1½ lines across, in 5-10-fl. clusters; pistillate solitary: fr. about ¼ in. across, greenish. July, Aug. S. Siberia to Amurland and N. China.

S. Auggeoides, Muell. Arg. (*S. japonica*, Miq.). Very similar to *S. ramiflora*: branchlets soon becoming brown or purple: lvs. usually more obtusish: pistillate fls. 2-5. Japan, Korea, N. and Cent. China. —*S. Leucopyrus*, Muell. Arg. = *Flüggea Leucopyrus*.

ALFRED REHDER.

SEDÁSTRUM (*Sedum* and *star*). *Crassulacææ*. A genus founded in 1905 to include seven species, most of which had been theretofore referred to *Sedum*, but differing from that genus in having erect rather than spreading carpels, slender styles, and other characters. Mexican caespitose perennials, with numerous sts. arising from a dense basal rosette of lvs. and dying to base after flowering: st.-lvs. alternate, mostly broad, fleshy: fls. in a more or less paniculate leafy infl.; calyx green and deeply cleft; corolla white or whitish, with distinct spreading lobes. Probably none is regularly in cult., but at least *S. ebracteatum*, Rose (*Sedum ebracteatum*, Moc. & Sesse), has been listed abroad: fl.-sts. about a foot long, ascending or procumbent, pubescent, leafy, somewhat branching, bearing sessile or short-pedicelled whitish fls.: basal lvs. obovate or spatulate, flattened and fleshy, hairy or at least ciliate on margins.

SÈDUM (Latin, *sedes*, to sit: the plants fix themselves on rocks and walls). *Crassulacææ*. Succulent herbs, rarely subshrubs, mostly hardy and perennial, useful for rockeries and one species, *S. spectabile*, a frequent showy border plant. See *Succulents*, Vol. V, page 2672.

Plants glabrous or glandular-pubescent, fleshy, erect or decumbent, sometimes caespitose or moss-like: lvs. very variable, opposite, alternate or whorled, entire or serrate; fls. cymose in a few axils and solitary, white, yellow, or rose, rarely red or blue, hermaphrodite or unisexual by abortion; calyx 4-5-lobed; petals 4-5 (rarely 6-7), free; stamens 8-10 (rarely 12-14); ovary 4-5-carpelled: follicles 4-5, free, many- or few-seeded.—About 280 species, mostly natives of the temperate and colder regions of the northern hemisphere. The hardy sedums are monographed, from a horticultural point of

view, by M. T. Masters in *Gardener's Chronicle* for 1878. Masters' descriptions and treatment have been partially followed in the present revision. The variability of the lf. is very noticeable both in thickness and breadth, some being thick and terete, others flat and thin, though all of them tending toward fleshy. Some are quite linear and from that they range to nearly 1½ in. broad. The margin is also variable from entire to deeply dentate. The synonymy of the species is much involved and in some groups, especially the *Telephium* group, the specific delimitation is very uncertain; in fact the whole genus needs monographic study. The present key is an attempt to differentiate the more prominent forms as they occur in horticulture and is based in part on literature and in part on herbarium specimens. It is unfortunately not altogether satisfactory but may prove of some value in separating the species.

Sedums are of the easiest culture. As a rule, they prefer sandy soil, and are very averse to a wet position in winter. Some are useful plants for carpeting poor and sandy waste places where few other things will grow. The little yellow-flowered plant with pulpy foliage that spreads in nearly every cemetery is *Sedum acre*. Sedums are also general favorites in all forms of rock-gardening. They are much used for carpet-bedding, especially the kinds with mealy or glaucous foliage, and those with various metallic shades of purple. In the hardy border, the more robust and bushy kinds, like *S. maximum* and *S. spectabile*, are preferred, though any of the lower-growing kinds are suitable for edgings and any of the evergreen kinds are welcome in winter when the hardy border shows few other bits of color or signs of life. As a rule, sedums like the sun, but a few of the species may help to solve the difficult problem of carpeting the ground underneath the trees where the soil is dry and shaded. Sedums are also favorites for baskets and vases, especially the kinds with trailing stems and minute leaves. For greenhouse decoration, *S. spectabile* is the favorite, as it is perhaps the showiest of the genus. It may be had in flower at any season of the year and remains in bloom a long time. It is also one of the favorite sedums for window-sills, balconies, and house-tops, especially in crowded cities. *Sedum acre*, however, is everybody's plant. A piece of it is often the only pleasant sight in an ugly city alley. Sedums can be propagated by seeds, but they are easily multiplied by the young offsets. These rosettes are somewhat bulb-like in nature and sedums could probably be propagated if it were worth while by using each leaf of a rosette. (Wilhelm Miller.)

 Woodwardii, 29.

KEY TO THE SPECIES.

- A. Lvs. terete or subterete (that is, relatively thick as compared to breadth).
 B. Fls. yellow (except a white-fl. variety of No. 1).
 C. Lf.-blades broad as compared to length.
 D. Petals without a dorsal awn.... 1. **acre**
 DD. Petals with a short dorsal awn.. 2. **Stahlian**
 CC. Lf.-blades narrow as compared to length (usually linear).
 D. Apex of lvs. blunt.
 E. The lvs. papillose-pilose..... 3. **multiceps**
 EE. The lvs. glabrous..... 4. **sexangulare**
 DD. Apex of lvs. acute or acuminate.
 E. Base of lvs. membranaceous and dilated, abruptly tapered to a much narrower upper part..... 5. **tenuifolium**
 EE. Base of lvs. not distinctly dilated, not abruptly tapered to a much narrower upper part.
 F. Petals acute or acuminate.
 G. Sepals subulate..... 6. **stenopetalum**
 GG. Sepals ovate-lanceolate.
 H. Apex of sepals acutish. 7. **sarmentosum**
 HH. Apex of sepals blunt.. 8. **Forsterianum**
 FF. Petals blunt.
 G. The lvs. incurved, those of the barren shoots forming dense conical rosettes..... 9. **rupestre**
 GG. The lvs. reflexed, those of the barren shoots not forming such marked rosettes..... 10. **reflexum**
 BB. Fls. white, pink, or purplish.
 C. Lf.-blades broad as compared to length.
 D. Sepals ovate..... 11. **anglicum**
 DD. Sepals oblong or linear to linear-lanceolate.
 E. Petals oblong and blunt.
 F. Color of fls. blue (sometimes rosy lilac)..... 12. **cæruleum**
 FF. Color of fls. white with the midrib of the petals pink. 13. **brevifolium**
 EE. Petals lanceolate and acute.
 F. Plant farinose-pruinose... 14. **farinosum**
 FF. Plant not farinose-pruinose though often more or less glaucous.
 G. Sts. much branched at the base: branches diffuse: fls. less than $\frac{1}{4}$ in. across..... 15. **dasyphyllum**
 GG. Sts. rather simple: branches short and not diffuse: fls. nearly $\frac{3}{8}$ in. across..... 16. **potosinum**
 CC. Lf.-blades narrow as compared to length.
 D. Petals relatively rather broad, their base somewhat narrowed.
 E. The lvs. oblong or oblanceolate-oblong..... 17. **pilosum**
 EE. The lvs. linear.
 F. Sts. viscid-pilose above: sepals ovate..... 18. **villosum**
 FF. Sts. not viscid-pilose though somewhat glandular-pilose above: sepals deltoid.. 19. **hispanicum**
 DD. Petals relatively narrow, usually lanceolate, their base broad.
 E. Barren shoots lacking..... 20. **arboresum**
- EE. Barren shoots present.
 F. Sepals lanceolate, relatively narrow..... 21. **pulchellum**
 FF. Sepals deltoid, ovate, oblong or elliptic, relatively broad.
 G. Infl. glandular..... 22. **monregalense**
 GG. Infl. not glandular.
 H. The infl. rather openly racemose-cymose..... 23. **Alberti**
 HH. The infl. more or less densely corymbose-cymose.
 I. Buds 5-angled: fls. pinkish..... 24. **lydium**
 II. Buds nearly terete, oblong: fls. white. 25. **album**
 AA. Lvs. flat (that is, relatively thin as compared to breadth).
 B. Fls. unisexual (dioecious).
 C. Color of fls. yellow..... 26. **Kirilowii**
 CC. Color of fls. greenish or reddish purple..... 27. **roseum**
 BB. Fls. bisexual (hermaphrodite).
 C. The fls. yellow or greenish yellow, one species orange-yellow (fls. of No. 30 become pink with age).
 D. The lvs. commonly not twice as long as broad (in No. 29 just about half as broad as long).
 E. Sepals ovate..... 28. **dendroideum**
 EE. Sepals linear to lanceolate.
 F. Margin of lvs. dentate above. 29. **Woodwardii**
 FF. Margins of lvs. entire.
 G. Petals united below..... 30. **oreganum**
 GG. Petals not united below.
 H. Apex of lvs. rounded or retuse..... 31. **spathulifolium**
 HH. Apex of lvs. apiculate. 32. **Palmeri**
 DD. The lvs. commonly much more than twice as long as broad (some specimens of No. 42 have the lvs. only twice as broad as long).
 E. Margin of lvs. entire.
 F. Lvs. in rosettes, at least those of the barren shoots. 33. **obtusatum**
 FF. Lvs. scattered.
 G. Petals oblong, boat-shaped..... 34. **nicæense**
 GG. Petals lanceolate.
 H. Sepals spatulate..... 35. **formosanum**
 HH. Sepals oblong..... 36. **japonicum**
 EE. Margin of lvs. dentate or serrate.
 F. Plant spreading-pilose... 37. **Selskianum**
 FF. Plant glabrous (sometimes glandular in No. 39).
 G. The sepals linear or linear-oblong.
 H. Outline of petals fusiform with the base slightly broadened and the apex long-acuminate..... 38. **Midden-**
 HH. Outline of petals lanceolate, apex acuminate..... 39. **hybridum**
 GG. The sepals lanceolate or oblong-lanceolate.
 H. Petals oblong..... 40. **asiaticum**
 HH. Petals lanceolate.
 I. Buds flask-shaped.. 41. **Maximowiczii**
 II. Buds conical.
 J. Lvs. oblong-ovate: plant about 6-8 in. high..... 42. **kamtschaticum**
 JJ. Lvs. oblong-lanceolate: plant usually $1\frac{1}{2}$ -2 ft. high..... 43. **Aizoon**
 CC. The fls. white, pink, red, violet, or purple.
 D. Lf.-blades $\frac{3}{4}$ -1 in. or more broad in the widest place.
 E. Plants pubescent or puberulent.
 F. Margin of lf. entire..... 44. **sempervivum**

- FF. Margin of lf. dentate-crenate.....45. oppositifolium
- EE. Plants glabrous. [folium
F. Lvs. noticeably petioled... 46. populifolium
FF. Lvs. sessile or nearly so.
G. Arrangement of lvs. in whorls of 3.....47. Sieboldii
- GG. Arrangement of lvs. opposite or alternate (rarely in whorls of 3 in No. 49).
H. Base of lvs. more or less cordate-clasping. 48. maximum
- HH. Base of lvs. more or less cuneate.
I. The lvs. opposite, rarely in whorls of 3.....49. spectabile
- II. The lvs. alternate (rarely opposite in No. 52).
J. Fls. greenish white; sepals broad-deltoid... 50. alboroseum
- JJ. Fls. some shade of pink.
K. Margin of lvs. nearly entire. 51. telephiodides
- KK. Margin of lvs. strongly dentate.
L. Blades of lvs. oblong-ovate.... 52. Telephium
- LL. Blades of lvs. lanceolate or elongate-lanceolate. 53. Fabaria
- DD. Lf.-blades $\frac{1}{2}$ in. or less broad in the widest place.
E. Lvs. of the barren shoots in whorls of 3.....54. ternatum
- EE. Lvs. not in whorls of 3.
F. Surface of lvs. densely papillose.....55. primuloides
- FF. Surface of lvs. not densely papillose.
G. Arrangement of lower lvs. opposite.
H. Petals ovate-oblong... 56. cyaneum
- HH. Petals lanceolate to lanceolate-oblong.
I. Outline of lvs. sub-orbicular.....57. Ewersii
- II. Outline of lvs. spatulate or obovate-cuneate.....58. stoloniferum
- GG. Arrangement of lower lvs. alternate (rarely opposite in No. 63).
H. Sepals blunt, oblong or linear-oblong.
I. Apex of lf. retuse... 59. Nevii
- II. Apex of lf. deltoid-acute.....60. retusum
- HH. Sepals acutish, lanceolate.
J. The lvs. oblong-spatulate.....61. Cepæa
- JJ. The lvs. more or less orbicular.
K. Margin of lf. entire.....62. Anacamp-seros
- KK. Margin of lf. crenate at the very obtuse apex.....63. stellatum

1. *acre*, Linn. (*S. neglectum*, Ten.). STONECROP. WALL PEPPER. LOVE ENTANGLE. Fig. 3583. Perennial, glabrous, caespitose: barren sts. creeping, branched, about 2 in. long; fl.-sts. 2-3 in. high: lvs. minute, about $\frac{1}{4}$ in. long, fleshy, ovate, crowded, gibbous at base, sessile: fls. yellow, about $\frac{1}{2}$ in. across, in 1-sided cymes, which have 2-5 forks; sepals lf.-like; petals lanceolate. Eu., N. Afr., E. Asia, and naturalized in N. Amer. Gn. 27, p. 316.—This is the commonest native species in

England and one of the commonest in cult. Thrives best in poor soil and is a good ledge-plant and is frequently used for covering rather arid spots which would otherwise be bare. The lvs. have an acid taste. Var. *album*, Hort., is a white-fl. form. Var. *aureum*, Mast., has the lvs. and shoot-tips bright golden yellow in spring. The yellow tint is lost later in the summer, but the variety is never so robust as the green form. Excellent for spring bedding, to give a bit of color. Var. *elegans*, Mast., has the tips and young lvs. pale silvery. More delicate than var. *aureum* and not so effective. Var. *hawaiianum*, Hort., is offered in the trade. Var. *majus*, Mast., is larger and more robust than the type: lvs. in 7 rows, deltoid-ovoid, scarcely auricled at base: fls. $\frac{3}{4}$ in. across, in a 2-parted cyme, with a central sessile fl.; sepals linear-oblong. Morocco. Var. *Maiveana*, Hort., is said by the trade to be the same as var. *hawaiianum*. Var. *sexangulare*, Hort., is offered in the trade; it probably is *S. sexangulare*.

2. *Stählii*, Solms. Perennial, trailing, much branched, puberulent: sts. green or pinkish; fl.-sts. 4-6 in. high: lvs. opposite or nearly so, sessile, nearly round in cross-section, ovoid or ellipsoid, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. yellow, 7-9 lines across, in few-branched terminal cymes, the branches of which are recurved; sepals puberulent, linear-oblong; petals lanceolate, with a short dorsal awn just below the apex. Mex.

3. *multiceps*, Coss. & Dur. Perennial, about 2-6 in. high, base subshrubby, much branched: barren shoots flexuous or erect, bearing dense rosettes of lvs. at their tips; fl.-sts. usually taller, erect: lvs. $\frac{1}{6}$ - $\frac{1}{4}$ in. long, glaucous or pruinose, pinkish and papillose, linear or oblanceolate, subterete: fls. pale yellow, about $\frac{1}{2}$ in. across, 5-merous, in many-branched, 2-6-fl., scorpioid cymes; sepals linear-oblong; petals oblong-lanceolate; anthers pale yellow. Algeria. G.C. II. 10:717.

4. *sexangulare*, Linn.? (*S. acre* var. *sexangulare*, Godr. *S. boloniense*, Lois. *S. Forsterianum*, Reichb., not Smith. *S. pulchellum*, Hort., not Michx.). Perennial, glabrous: barren shoots ascending 2-3 in., branched; fl.-st. erect, 2-3 in. high, very slender: lvs. densely crowded in 6-7 rows, about 2 lines long, linear-cylindrical, slightly gibbous at base: fls. yellow, $\frac{1}{2}$ in. across, in a 3-5-branched umbellate cyme, 1-3 in. diam.; sepals linear-oblong; petals lanceolate. Eu. The Linnean material probably differs very little from *S. acre*, but the horticultural material (especially the European) may be distinct.

5. *tenuifolium*, Strobl. (*S. amplexicaule*, DC. *Semprevivum tenuifolium*, Sibth. & Smith). Perennial, glabrous, evergreen: barren branches 2-4 in. long, slender, wiry, ascending; fl.-sts. decumbent, ascending, about 6-9 in. high: lvs. of the barren shoots dilated and membranous at base, gradually tapering to a long awl-like point; of the fl.-sts. alternate, sessile, $\frac{1}{2}$ in. long, terete, with a membranous auricle at base: fls. numerous, golden yellow, secund in 2-forked cymes, with a sessile fl. in the fork; sepals ovate, oblong, acute, united below into a cup-shaped tube; petals oblong-lanceolate, $\frac{1}{4}$ in. long, keeled; filaments greenish, anthers yellow. Medit. region.—There are often 6-10 petals in this species.

6. *stenopetalum*, Pursh. Perennial, tufted, glabrous: sts. 3-6 in. high, erect from a decumbent base: lvs. crowded on the barren shoots, sessile, linear or lanceolate, $\frac{1}{2}$ in. long, terete: fls. bright yellow, in much-branched scorpioid cymes; sepals subulate; petals linear-lanceolate, acuminate. Alberta to S. D., Neb., New Mex., and Calif.

7. *sarmentosum*, Bunge. Perennial, glabrous: shoots slender and prostrate: lvs. crowded, opposite or whorled, $\frac{1}{2}$ - $\frac{3}{4}$ in., linear, terete or slightly flattened: fls. bright yellow, $\frac{1}{4}$ in. across, numerous, in a flat-topped, umbellate, 3-5-forked cyme, with a solitary fl. in the forks; branches recurved, the fls. on the upper surface only;

sepals ovate-lanceolate, fleshy; petals lanceolate; stamens yellow. China. Var. *carneum*, Hort. (*S. carneum variegatum*, Hort.), has pink sts.: lvs. with a marginal stripe of white or cream-color.—A good greenhouse plant and also good for edging.

8. *Forsterianum*, Smith. Perennial, forming small tufts, glabrous or slightly glaucous: lvs. of the barren shoots many-ranked, forming terminal rosettes, oblanceolate or lanceolate, flattened but subterete, spurred at the base: fls. yellow, in a compact, round-

3583. Stonecrop, or wall pepper.—*Sedum acre*. ($\times \frac{1}{2}$)

topped cyme; sepals ovate; petals lanceolate. England.

—This is now kept distinct, but it has been referred to *S. rupestre* and also to *S. pruinaum*, a species which does not seem to be in cult. and it has also been treated as a variety of both these species. Var. *glanduliferum*, Hort., is offered in the trade.

9. *rupestre*, Linn. Perennial, glaucous, reddening with age and drought: barren shoots numerous, creeping, 1-3 in. long; fl.-sts. ascending or erect, 6-12 in. high: lvs. $\frac{1}{2}$ in. long, in numerous rows, linear, subulate, incurved, flattened above, forming dense conical rosettes which are $\frac{3}{4}$ -1 in. diam., at the ends of the sterile shoots: fls. numerous, yellow, barely $\frac{1}{2}$ in. across, 5-7-merous, in umbellate, 3-5-forked, ultimately hollow-topped cymes; sepals ovate, oblong; petals ovate, oblong; anthers yellow. W. Eu. Closely allied to and confused with *S. reflexum*. Var. *spirale*, Hort., is offered in the trade.

10. *reflexum*, Linn. (*S. collinum*, Willd.). Perennial, glabrous: sts. trailing; fl.-sts. erect, 8-10 in. high: lvs. in 6 or 7 rows, crowded on the barren shoots into a conical mass, but not forming so marked a rosette as in typical *S. rupestre*, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, linear-subulate, reflexed, terete, gibbous at base: fls. 4-8-merous, yellow, $\frac{3}{4}$ in. across, in a decurved, many-fl. umbellate cyme which is many-branched, with a fl. in each fork; sepals oblong-lanceolate; petals linear; anthers yellow. Eu. Also escaped in N. E. N. Amer. Var. *albescens*, Mast. (*S. albescens*, Haw. *S. glaucum*, Smith), is glaucous: lvs. rarely in rosettes: fls. $\frac{1}{2}$ in. across, 6-merous. Eu. and N. Afr. Var. *cristatum*, Mast. (*S. monstrum*, Hort. *S. robustum*, Hort.), has the sts. fasciated so as to form a crest like a cockscomb. Var. *virescens*, Mast. (*S. virescens*, Willd.), is similar to var. *albescens*, but has pale sulfur-yellow fls.—This species and its varieties are treated by some authorities as a part of *S. rupestre*.

11. *anglicum*, Huds. Perennial, about 3 in. high, glabrous, evergreen: barren shoots trailing or erect, forming dense masses; fl.-sts. about 2 in. high: lvs. crowded, alternate, on the fl.-sts. somewhat opposite and less crowded, $\frac{1}{8}$ - $\frac{1}{4}$ in. long, ovate or ovate-lanceolate, green, becoming red-tinged: fls. white or rosy tinted, about $\frac{3}{8}$ in. across, in

few-fl. dichotomous cymes; sepals ovate; petals lanceolate; anthers red, becoming black. W. Eu. Gn. 79, p. 366.—A good plant for the rockery, though rather difficult to grow.

12. *caeruleum*, Linn.; also spelled *caeruleum* (*S. azureum*, Desf.). Fig. 3584. Annual, glabrous, or pilose in the infl.: sts. 2-3 in. high, branched from the base: lvs. tufted, $\frac{1}{4}$ in. long, oblong, obtuse, pale green, spotted with red: fls. pale blue to rose-lilac, $\frac{1}{4}$ in. across, 5-7-merous, in a lax, many-fl. cyme, which is 1 in. diam.; sepals oblong; petals oblong; anthers reddish brown. Medit. region. B.M. 2224. B.R. 520. Gn. 27, p. 315.—Said to thrive in a sandy soil, and to be adapted to carpet-bedding.

13. *brevifolium*, DC. Perennial, said to grow about 4 in. high, glaucous, tufted: lvs. crowded in 4 rows, about $\frac{1}{10}$ in. long, ovoid, subglobose, pinkish, densely mealy pubescent: fls. white, $\frac{1}{4}$ in. across, in an umbellate, 2-3-forked cyme, with a pedicellate fl. in the center of each fork; sepals oblong-lanceolate, whitish with a pink midrib; petals oblong, with a pink midrib; anthers pink. France and Medit. region. —Closely related to *S. dasyphyllum* of which some authorities have made it a variety. Rather tender and sensitive to root-moisture. Var. *album*, Hort., is said to have bronzy lvs. and to grow 6 in. high. Var. *Pötsii*, Hort., is offered in the trade as a form with tiny round lvs., covered with white meal.

14. *farinidum*, Lowe. Perennial, glaucously pruinose, glabrous: sts. tufted, creeping, much branched: lvs. crowded in 4-6 rows, deciduous, $\frac{1}{2} \times \frac{1}{4}$ in., oblong, very obtuse: fls. white or flesh-color, nearly sessile, $\frac{1}{2}$ in. across, crowded in a 2-3-parted cyme, 5-7-merous; calyx-tube very short, segms. linear-oblong, pink-tipped; petals lanceolate, acute, keeled; anthers purplish brown. Madeira.—Masters says that most of the material cult. under this name is really *S. album*.

15. *dasyphyllum*, Linn. (*S. glaucum*, Lam.). Perennial, about 2-4 in. high, glabrous: sts. tufted, slender, branching: lvs. crowded, sessile, spreading, oblong-acute or suborbicular, thick, studded with crystalline pimples: fls. white to pinkish, about $\frac{1}{2}$ in. across, in lax, few-fl., corymbose cymes; sepals oblong, fleshy; petals lanceolate; anthers black. Eu., N. Afr.—The material cult. under the name of *S. glaucum* probably belongs here; see also *S. rupestre* and *S. hispanicum*. Var. *glanduliferum*, Moris (*S. corsicum*, Duby), has minute gray-green lvs. which are more or less densely glandular-pubescent: fls. white. Corsica and N. Afr. B.M. 6027.

There is a form of this offered in the trade under the name of *S. corsicum* var. *grandiflorum*, Hort.

3584. *Sedum caeruleum*. (Natural size)

16. *potosinum*, Rose. Sts. low and weak, at first erect, but soon prostrate or at most ascending; fl.-sts. 2-4 in. high, slender: lvs. crowded, rhomboid-subsppherical, nearly terete, $\frac{1}{4}$ - $\frac{3}{8}$ in. long, obtuse, pale green, glabrous, papillose(?), slightly glaucous: fls. white or tinged pink, terminal and few; sepals linear; petals lanceolate, acuminate, widely spreading. Mex.—A rare species.

17. *pilòsum*, Bieb. (*S. Regelii*, Hort., not Kuntze). Fig. 3585. Biennial, 2-3 in. high, glandular-pubescent: st. leafy: lvs. $\frac{1}{8}$ - $\frac{1}{2}$ in. long, oblong or oblanceolate-oblong; radical densely rosulate; cauline alternate, rather close together: fls. rose-pink, clustered in a corymbose cyme, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. diam.; sepals oblong; petals elliptic-lanceolate, narrowed to a broad claw; anthers red. Caucasus and Asia Minor. B.M. 8503. G.C. III. 49:347. G.M. 58:37.

18. *villòsum*, Linn. Annual, 3-4 in. high: sts. rather simple, erect, viscid-pilose above: lvs. alternate, subterete, rather remote, linear, obtuse: fls. dull rose or white, in a small, rather loose, few-fl., terminal cyme; sepals ovate and green; petals ovate, rather acute. Alpine and N. Eu.—One of the few species that likes a moist situation, suitable for a bog or similar location.

19. *hispànicum*, Linn. (*S. glaucum*, Waldst. & Kit., not Smith. *S. pallidum*, Ten., not Bieb.). Annual or biennial (Masters says perennial), glaucous, glabrous or glandular-pilose above: barren shoots 2 in. long, branched; fl.-sts. 3-4 in. high, reddish: lvs. densely crowded, about $\frac{1}{4}$ in. long, linear, greenish gray, becoming reddish, studded with fine hyaline pimples at the tips: fls. 6-merous, pinkish white, in 3-7-branched, umbellate cymes; sepals deltoid; petals oblong, narrowed at base. Cent. and S. Eu., Spain is uncertain.—Commonly grown under the name of *S. glaucum*; see also *S. dasyphyllum* and *S. rupestre*.

20. *arbòreum*, Mast. Perennial, subshrubby, about 4-6 in. high, glabrous, evergreen; branching from near the base, with no separate barren shoots: lvs. of the older shoots deltoid, subulate, terete or somewhat 4-sided, $\frac{1}{8}$ in. long, horizontally spreading; of the younger shoots more or less crowded, linear, terete: fls. white, 5-merous, about $\frac{1}{2}$ in. across, in many-fl. terminal cymes; sepals linear-oblong; petals lanceolate, keeled; filaments white. Hab.(?).

21. *pulchèllum*, Michx. (*S. pulchum*, DC.). Perennial, glabrous, trailing or ascending: branches slender, 3-6 in. long: lvs. in several rows, linear, scarcely $\frac{1}{2}$ in. long, terete, pointed, gibbous at base: fls. rosy purple, $\frac{1}{2}$ in. across, in a 3-4-branched cyme, with fls. erect and crowded in 2 rows along the upper surface, each with a leafy bract; sepals lanceolate, obtuse; petals lanceolate; anthers orange. Va. to Ga., Ind., Mo., and Texas. B.M. 6223. Gn. 27, p. 315. G.C. II. 10:685.—The minute lvs. assume rich tints of red, brown, and purple. The branches of the infl. are 3-4 in. long and gracefully arched.

22. *monregalènze*, Balb. (*S. cruciatum*, Desf.). Perennial, glabrous except the infl., which is glandular: barren shoots spreading, erect, or creeping, 1-4 in. long: lvs. of barren shoots crowded, linear or obovate-oblong, $\frac{1}{8}$ - $\frac{1}{4}$ in. long; those of the flowering shoots scattered, narrower and often spotted pink: fls. white, $\frac{1}{4}$ in. across, 5-merous, in a terminal, lax, many-fl. panicle cyme; sepals deltoid, pink-spotted; petals deltoid-lanceolate, acuminate, pinkish brown beneath; anthers pinkish. N. Italy and Corsica. L.B.C. 5:464.

23. *Àlberti*, Regel. Perennial: sts. procumbent, creeping, branched, terete; sterile branches short, densely leafy; flowering much elongated, laxly leafy: lvs. linear-oblong, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, semi-terete below, glabrous: fls. white, about $\frac{1}{2}$ in. across, short-pedicelled, in an erect corymb, dichotomously erect-spreading, branched; sepals elliptic; petals lanceolate. Siberia, Turkestan. G.M. 56:189. Gt. 29:1019.

24. *lydium*, Boiss. Perennial, glabrous, caespitose: barren shoots 2-3 in., erect, reddish; fl.-sts. 4-5 in. high: lvs. crowded, $\frac{1}{4}$ in. long, linear, subterete, greenish or red-tipped, base auricled, with numerous fine pimples at the tip when seen under a lens: fls. pinkish, $\frac{1}{4}$ in. across, in a many-fl., corymbose cyme; buds 5-angled; sepals oblong, reddish; petals lanceolate, rather obtuse;

anthers reddish. Asia Minor. G. 37:25.—A good plant for rockeries. Some of the material grown in gardens as *S. pulchellum* and *A. anglicum* are really this species. Var. *aureum*, Hort., was offered in the trade. Var. *glaucum*, Hort., is offered in the trade as a glaucous-lyd. form.

25. *álbum*, Linn. Perennial, about 4-6 in. high, glabrous, caespitose: barren sts. erect or creeping, rooting, olive-brown; fl.-sts. erect, pinkish: lvs. alternate, spreading, linear-oblong, about $\frac{1}{2}$ in. long, obtuse: fls. white, about $\frac{1}{4}$ in. across, in corymbose cymes, which are much branched, about 2-3 in. diam.; calyx-tube cup-shaped, segms. broadly ovate to subrotund, obtuse; petals lanceolate; anthers reddish. Eu., Temp. Asia, and N. Afr. Gn. 27, p. 315. G.M. 57:469.—Some of the plants grown as *S. neglectum* probably belong to this species.

26. *Kirilòwii*, Regel. Perennial, rhizome destitute of shoots of preceding years, green, glabrous: sts. up to 1 $\frac{1}{2}$ ft. high, slender: lvs. spreading, elongate-linear, 2-3 in. long, attenuate, more or less serrate toward the tip: fls. dioecious, yellow, 5-merous, rather small, in a dense, many-fl., corymbose cyme, which is commonly leafy; sepals and petals linear. Soongaria, China, and Turkestan.—Allied to *S. roseum*.

27. *ròseum*, Scop.

(*Rhodiola rosea*, Linn. *S. Rhodiola*, DC.).

Perennial, 4-8 in. high: root-stock thick, fleshy, exhaling a perfume of rose-water: sts. annual, several from the same stock, erect and unbranched: lvs. scattered, glaucous, 1 x $\frac{1}{4}$ in., sessile, flat, spatulate, obovate or oblong, obscurely 1-nerved, slightly toothed at apex: fls. dioecious, greenish or reddish purple, in a terminal flat-topped, subglobose cyme, about 1 in. diam.; sepals 4, lanceolate or oblong; petals 4, linear-oblong; stamens 4 in the male, lacking in the female fls. Eu., N. Amer., and Himalaya. Gt. 12:403 (as var. *lanceolatum*). B.B. (ed. 2) 2:207.—A neat-growing species well adapted to the rockery. Var. *linifolium*, Hort., is offered in the trade.

28. *dendroideum*, Moq. & Sessé. Shrub, 4-12 in. high, much branched, smooth: lvs. flat, fleshy, obovate or spatulate, sessile, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. sessile or nearly so, bright yellow, in a paniculate cyme, numerous; calyx-lobes ovate; petals lanceolate. Mex.

29. *Woodwardii*, N. E. Br. Perennial, glabrous: sts. simple, about 1 ft. high, green: lvs. alternate, lax, 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ x $\frac{3}{4}$ -1 $\frac{1}{4}$ in., obliquely cuneate-obovate, irregularly and obtusely dentate above, green, flat: fls. yellow, sessile, about $\frac{1}{2}$ in. across, in dichotomously branched, 2-5-parted, rather flat, rather lax cymes, which are 2 $\frac{1}{2}$ -4 in. diam.; sepals linear-subulate; petals lanceolate. China(?).—Resembles *S. Aizoon*, but differs in the obliquely obovate, obtusely toothed lvs. and larger, looser cymes.

30. *oregànum*, Nutt. (*Gormánia oregàna*, Brit.). Perennial, glabrous: fl.-sts. erect, simple, 3-6 in. high: lower lvs. about $\frac{1}{4}$ in. long, all spatulate-cuneate, rounded at apex: fls. yellow, changing with age to pink, in a compound cyme; sepals lanceolate to ovate-lanceolate; petals linear-lanceolate, long-acuminate, more than $\frac{1}{2}$ in. long. Alaska to N. Calif.

31. *spatulifolium*, Hook. Fig. 3586. Perennial with slender rootstocks, glaucous, ultimately reddish: barren shoots creeping or ascending, 3-4 in. long; fl.-sts.

3585. *Sedum pilosum*. (x1/4)

ascending, sometimes 4-8 in. high, simple or sometimes branched: lvs. of barren shoot forming a terminal rosette 1-1½ in. diam. and producing offsets from the base; lower lvs. obovate-spatulate, ½ x ⅜ in.; cauline smaller and clavate: fls. numerous, yellow, ½ in. across, in terminal forking cymes, with 3-5 principal branches about 3 in. long, these are 2-divided and bear fls. only on the upper side; sepals lanceolate or oblong-lanceolate; petals lanceolate, keeled; anthers yellow. N. W. N. Amer. G.C. II. 5:821; 10:377. Gn. 24:462. Gt. 21:741.—Questionable whether it is hardy in the E.

32. *Pálmeri*, Wats. Perennial, caulescent, about 6 in. high, erect and branching, glabrous and glaucous: lvs. thick, flattened, 1-1½ x ¼ in., spatulate-obovate, slightly apiculate: fls. deep orange, in a racemose panicle whose branches are 1-2 in. long; sepals narrowly lanceolate; petals narrowly lanceolate. Mex.

33. *obtusátum*, Gray (*Gormánia obtusáta*, Brit.). Perennial, glaucous or green: sts. prostrate or ascending, 2½-6 in. high; fl.-sts. erect, terete, reddish, ultimately leafless: lvs. rosulate, 1 x ⅜ in., spatulate, entire, glaucous, becoming reddish green: fls. yellow, ¼ in. across, in terminal, spreading, umbellate cymes, 1½-2 in. diam.; sepals oblong-acute; petals lanceolate; anthers yellow. Calif.

34. *nicæense*, All. (*S. ochroleucum*, Chaix. *S. altissimum*, Poir.). Perennial, glabrous and glaucous: root-stock thick and woody: sts. 6-8 in. long, at first prostrate, afterward ascending; fl.-sts. erect, 10-12 in. high: lvs. of barren shoots ascending or spreading, ½-¾ in. long, glaucous, reddish when old, ovate-lanceolate or oblong-lanceolate, scarcely auricled; of flowering

3586. *Sedum spathulifolium*. (× ¼)

ing shoots appressed, lanceolate, distinctly auricled: fls. greenish yellow, 5-6-merous, ½ in. across, in terminal many-fld., leafless umbellate cymes; sepals deltoid-lanceolate; petals oblong, boat-shaped; anthers yellow. Medit. region.. G.M. 57:473.—*S. ochroleucum* is kept distinct by some but does not seem to differ very much.

35. *formosánum*, N. E. Br. Annual, about 6 in. high, glabrous: st. repeatedly dichotomously or trichotomously branched from near the base, indistinctly 4-sided: lvs. 1-3 in whorls at the branchings of the sts., with 1-3 on the long internodes, 1-1¼ x ½ in., flat, spatulate: fls. sessile, yellow; sepals green, fleshy, spatulate; petals lanceolate; anthers at first red, finally black. Formosa.—Intro. into S. Calif.

36. *japónicum*, Sieb. Perennial, 4-6 in. high, glabrous: sts. diffuse: lvs. scattered or opposite, elliptical to spatulate, flat and somewhat reticulate veined, entire, bright green, channeled above: fls. yellow, ½ in. across, in loose, terminal and lateral, paniced, many-fld. cymes; sepals oblong; petals lanceolate. Japan.—It is extremely doubtful whether this species is or has been common in cult.; most of the material so named is probably *S. alboroseum*. Var. *auréo-marginátum*, Hort., probably is the same as *S. kamschaticum* var. *auréo-marginatum*. Var. *macrophyllum*, Hort., is offered in the American trade as a compact bush, 15 in. high, with waxy white fls., the centers of which are light pink; presumably this is also *S. alboroseum*. Var. *variegátum*, Hort., mentioned in American trade is presumably *S. alboroseum* var. *variegatum*, which is a large-lvd. plant with decided yellow-blotched lvs.

37. *Selskiánum*, Regel & Maack. Perennial, spreading, pilose: sts. 1-1½ ft. high, erect: lvs. sessile, ascend-

ing, upper 1½ by less than ½ in., lanceolate from a broad base, ciliate, apical third serrate-margined: fls. numerous, yellow, about ¼ in. across, in a many-branched terminal cyme which is hollow-topped and leafy; sepals linear; petals lanceolate; anthers yellow. Amurland, Manchuria. Gt. 11:361.—Close to *S. Aizoon*, but differs in the pilose sts. and the narrower and pilose lvs.

38. *Middendorffianum*, Maxim.; also spelled *Middendorffii*. Perennial, 4-16 in. high, caespitose, glabrous: lvs. ½ to nearly 3 in. long, lowest spatulate; the rest linear-spatulate, upper part serrate, upper surface channeled: fls. yellow, ⅝-¾ in. across, in many-fld. cymes; sepals linear-oblong; petals fusiform, base rather broad, apex long-acuminate; anthers dark purple. Amurland.—Some of the taller material grown under this name probably does not belong to this species. Var. *hybrídum*, Hort., a form said to have fine autumn tints, is offered in the trade.

39. *hybrídum*, Linn. Perennial: sts. creeping, glabrous or glandular: lvs. alternate, petioled, about 1 or more by ½ in., spatulate, upper half coarsely toothed, lower part entire and tapering; teeth red-tipped: fls. numerous, yellow, in terminal, much-branched, umbellate, inversely pyramidal cymes which are 2-3 in. diam.; sepals linear; petals apiculate; anthers orange. Siberia and China.

40. *asiáticum*, Spreng. (*S. Wallichianum*, Hook.). Perennial, 6-12 in. high: sts. annual, erect, unbranched, glabrous, slender: lvs. opposite, decussate, sessile, ¾-1 in. long, linear, oblong, coarsely and irregularly toothed: fls. numerous, greenish yellow, bisexual, in compact, terminal, globose cymes; sepals oblong-lanceolate; petals oblong; anthers orange-brown. Himalayas.—Readily distinguished by its almost pinnatifid foliage. In India the fls. are said to be sometimes red. It seems to suffer from wetness in winter and probably should be wintered under glass or otherwise protected from the wet.

41. *Maximòwiczii*, Regel. Perennial, about 1 ft. high, glabrous: sts. erect, terete or somewhat 4-sided, greenish: lvs. subopposite or alternate, subsessile, 1-1½ in. long, oblong-ovate or oblong-lanceolate, regularly toothed; upper lvs. longer and narrower: fls. yellow, numerous, in a dense flat spreading cyme; buds flask-shaped; sepals unequal in size, lanceolate, rarely somewhat spatulate at apex; petals lanceolate. Japan, Amurland. Gt. 15:528. Gn. 19, p. 203; 27, p. 316.—Similar to *S. Aizoon* and by some considered a variety of it. Differs in having unequal sepals and the peculiar flask-shaped buds. A good border plant. *S. Lehmannii* of some gardens belongs here.

42. *kamschaticum*, Fisch. & Mey. Perennial, glabrous: branches 6-10 in. long, greenish or pinkish; fl.-sts. erect, 4-6 in. high: lvs. alternate or opposite, about 1¾ x ½ in., oblong-ovate, deep green, coarsely but regularly toothed above the middle, tapering gradually to the petiole: fls. numerous, yellow, ¾ in. across, in terminal, umbellate inversely pyramidal cymes which are 1-3 in. diam.; sepals greenish, deltoid; petals lanceolate, apiculate, keeled; anthers subglobose, orange. Kamschatka, Korea, and Japan. Var. *auréo-marginátum*, Hort., is offered in the trade; *S. japonicum* var. *auréo-marginatum* probably is the same thing. Var. *variegátum*, Hort., is offered in the trade as having variegated lvs. and yellow fls. By some dealers the fls. of the plants are said to be purple and the material so named is undoubtedly misnamed and is probably some form of *S. Telephium* or one of its close allies.

43. *Aizoon*, Linn. Perennial, glabrous, 1 ft. or more high, usually 1½-2 ft.: sts. several, unbranched, erect, subangular: lvs. alternate, sessile, distant, oblong-lanceolate, 2½ x ¾ in., coarsely and irregularly toothed:

fls. numerous, yellow, $\frac{1}{2}$ in. across, in a loose paniced cyme, 1-3 in. diam.; sepals lanceolate; petals lanceolate. Siberia.—An old garden plant, suitable for rockeries or borders.—Some of the material grown as *S. Wallichianum* probably is this species.

44. *sempervivoides*, Fisch. (*S. Sempervivum*, Ledeb.). Biennial, pubescent, 2-8 in. high: basal lvs. in a rosette of 40-50, obovate, cuneate, pubescent and ciliate, about $1 \times \frac{3}{4}$ in., cauline clasping, greenish red, oblong, acute:

3587.
Sedum Sieboldii.

fls. scarlet, in a many-fl., paniced cyme, which is 2-4 in. diam.; sepals deltoid, acute, pilose; petals lanceolate, $\frac{3}{4}$ in. long. Asia Minor and Caucasus. Gt. 16:551; 33:1155. Gn. 19:354. R. H. 1846:5.—Apparently rare in cult., but said to be very showy; the fl.-color is almost unique in the genus.

45. *oppositifolium*, Sims. Perennial, trailing, puberulent: fl.-sts. erect, 6 in. high: lvs. opposite, decussate, $1\frac{1}{2} \times \frac{3}{4}$ -1 in., obovate-spatulate, dentate-lobulate or crenate, slightly puberulent: fls. white, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, in a terminal dichotomous cyme; sepals lanceolate; petals oblong-lanceolate; anthers orange according to Masters. Caucasus and Persia. B.M. 1807 (anthers shown as yellow).—Closely allied to *S. stoloniferum*, but the lvs. are brighter green and more regularly decussate.

46. *populifolium*, Pall. Subshrub, with fibrous roots, glabrous: sts. 6-10 in. high, greenish or purplish, slender, branched: lvs. alternate, distant, $1\frac{1}{2} \times 1$ in., petioled, ovate, acute, base cordate, coarsely and irregularly toothed; petiole $\frac{3}{4}$ -1 $\frac{1}{4}$ in. long: fls. numerous, nearly $\frac{1}{2}$ in. across, whitish or pinkish, in terminal, much-branched, corymbose cymes; sepals lanceolate; petals lanceolate, 1-nerved; anthers purple. Siberia. B.M. 211. Gn. 27, p. 316. R.H. 1857, p. 150.—Readily distinguished by the long-petioled, poplar-like lvs. A good border or rockwork plant, also useful as a pot-plant.

47. *Sieboldii*, Sweet. Fig. 3587. Subshrubby, 6-8 in. high, glaucous: branches terete, slender, purplish, erect, afterward decurved: lvs. in whorls of 3, sessile or nearly so, suborbicular, sinuate, about $\frac{3}{4}$ -1 in. diam., bluish green, margins pinkish, base cuneate: fls. pink, $\frac{1}{2}$ in. across, numerous, in much-branched umbellate cymes; sepals ovate-acute; petals lanceolate; anthers pinkish. Japan. B.M. 5358. G. 34:831.—Very useful for rockeries and borders. Var. *variegatum*, Hort. (*S. variegatum*, Hort., not Wats. *S. Sieboldii splendens variegatum*, Hort.), has white variegated lvs. I.H. 10:373 (lvs. green-margined, center yellow).

48. *maximum*, Suter (*S. macrophyllum*, Hort. Vilm.). Perennial, stout and bushy: sts. 1-2 ft. high, erect, green or purple: lvs. opposite, sessile, spreading, st-clasping, $2\frac{1}{2}$ in. long, ovate-acute, more or less cordate, crenate or dentate: fls. whitish, in terminal and lateral cymes, on long peduncles, forming a loose panicle; cymes rather globose and many-fl.; sepals deltoid-lanceolate; petals lanceolate, with the tips spotted with red; anthers reddish, projecting. Eu., Caucasus, and N. W. Asia. Gn. 27, p. 316.—A very variable species and occurs in many forms. A fine border plant, but is apt to become straggly in the fall and to need support. Var. *haematodes*, Mast. (*S. atropurpureum*, Hort., not Turcz. *S. maximum* var. *atropurpureum*, Hort. *S. mac-*

rophyllum var. *atropurpureum*, Hort.), has sts. erect, glabrous, $1\frac{1}{2}$ -2 $\frac{1}{2}$ ft. high; lvs. opposite, oblong-ovate, bronzy or dark purple; petals whitish, red-tipped. G.C. II. 10:337. Var. *purpureum*, Hort. (*S. macrophyllum* var. *purpureum*, Hort.), is a purple-lvd. form questionably different from the preceding variety. Var. *variegatum*, Hort., has been offered in the trade as a form with green-and-gold foliage. Var. *versicolor*, Van Houtte (*S. Rodigasii*, Hort.), is a form with pink sts. and lvs. heavily variegated with white, their margins pink. F.S. 16:1669.

49. *spectabile*, Bor. (*S. Fabaria*, Hort., not Koch). SHOWY SEDUM. Fig. 3588. Perennial, robust and glaucous: sts. 18-24 in.: lvs. opposite, decussate or in whorls of 3, 3×2 in., flat, scarcely petioled, ovate or spatulate, entire or obscurely sinuate-dentate: fls. numerous, $\frac{1}{2}$ in. across, pink, in large flat-topped, inversely pyramidal, leafy and umbellate cymes; sepals whitish, linear-lanceolate; petals slightly concave; anthers orange. Japan(?). Gn. 27, p. 315. I.H. 8:271. Gt. 21:709.—The fls. are said to vary from rose to purple and perhaps to white. This is the showiest of the sedums and is an excellent border and garden plant. It is said to thrive best in stiff clay and not to do so well in lighter soils. Var. *album*, Hort., a white-fl. form is offered in the trade. Var. *atropurpureum*, Hort., is a form with rosy crimson fls. Var. *purpureum*, Hort., is offered in the trade. Var. *roseum*, Hort., is offered in the trade. Var. *rubrum*, Hort., is a form with crimson fls. There is also a form with variegated lvs.

50. *alboroseum*, Baker (*S. erythrostictum*, Mast., not Miq. *S. japonicum*, Hort., not Siebold. *S. macrophyllum*, Hort., not Hort. Vilm.). Perennial, glaucous: sts. several, ascending, about $1\frac{1}{2}$ ft. high, glabrous: lvs. up to $2\frac{1}{2} \times 1\frac{1}{4}$ in., alternate in 4 ranks, slightly convex below, oblong-spatulate, upper margin incised-crenate: fls. greenish white, in a dense corymbose cyme, 3-4 in. diam.; sepals deltoid; petals lanceolate; anthers pinkish: carpels rosy pink. Japan. Gt. 21:709.—A fine plant for the border or rockery. Var. *variegatum*, Hubb. (*S. erythrostictum* var. *variegatum*, Mast. *S. japonicum* var. *variegatum*, Hort. ex W. Mill.), has the lvs. irregularly blotched yellow in the center. Gt. 21:709.

51. *telephioides*, Michx. Perennial, glabrous: sts. 6-10 in. high: lvs. scattered, 2×1 in., oblong or obovate, nearly entire or sparingly toothed, base cuneate: fls. numerous, flesh-colored, in small, dense, compound cymes, 1 - $1\frac{1}{2}$ in. diam.; sepals lanceolate; petals lanceolate, falcate, hooded at the tip. S. Pa. to W. N. Y., to S. Ind., N. C., and Ga.—Not common in cult.

52. *Telephium*, Linn. ORPINE. LIVE-FOREVER. Fig. 3589. Perennial: sts. erect, 12-18 in. high: lvs. scat-

3588. Showy sedum.—*Sedum spectabile*. Clusters 4 inches across.

tered, rarely opposite, 2 - 3×1 - $1\frac{1}{4}$ in., oblong-ovate, dentate; lower wedge-shaped at base; upper somewhat rounded: fls. numerous, pink, red-spotted or sometimes pure white, in dense terminal and lateral, pedunculate cymes; sepals lanceolate; petals lanceolate, 2 - $2\frac{1}{2}$ lines long, somewhat recurved. Cent. Eu. to Siberia and naturalized in N. Amer.(?). (The American material may be another species which it is almost impossible to distinguish horticulturally, namely *S. purpureum*, Tausch., and which is referred to *S. Telephium* by many authors.) Var. *Bórderi*, Mast. (*Anacampseros Bórderi*, Jord. & Fourr. *S. Bórderi*, Hort. *S. Anacampseros* var. *Bórderi*, Hort.), has reddish sts.: lvs. distinctly petioled, oblong, tapering at base: fls. pink, in

a flat-topped, corymbose cyme. Var. *hýbridum*, Hort., is offered in the trade. Var. *purpuráscens*, Hort., is offered in the trade. Var. *purpureum*, Hort. (not to be confused with *S. purpureum*, Tausch.), is offered in the trade as a purple-ld. form; very possibly this is the same as *S. maximum* var. *purpureum*. Var. *rúbrum*, Hort., is offered in the trade.—The species and all of its

varieties are excellent border and garden plants, also well adapted to the richer parts of the rock-garden. A very variable and confusing species.

3589. Live-forever.—*Sedum telephium*. ($\times \frac{1}{2}$)

turally fairly distinct, as fls. smaller.

54. *ternátum*, Michx. Fig. 3590. Perennial by root-stocks, glabrous, tufted: barren shoots 6–8 in. long, prostrate and creeping; fl.-sts. erect: lvs. $\frac{1}{2}$ in. long, in whorls of 3, flat, obovate to suborbicular spatulate, crowded in rosettes at end of the barren shoots; those of the fl.-sts. scattered, oblong, acute: fls. white, $\frac{1}{2}$ in. across, 4-merous, in 1-sided, leafy, terminal, 3–5-parted cymes; sepals oblong; petals oblong, acute; anthers reddish. N. Y. and N. J. to Ga., Ind., Mich., and Tenn. B.M. 1977. B.R. 142. G.M. 57:840.

55. *primuloides*, Franch. Rhizome thick, branched: branches of st. short and fastigiately clustered: lvs. clustered in a terminal rosette, densely papillose, more or less long-petioled, broad-spatulate, 5–10 lines long including the petiole, entire: peduncles 1-fl'd., short: sepals narrowly lanceolate; petals white, broadly ovate, about $\frac{1}{2}$ in. long. China. G.M. 57:212.—Apparently rare in cult.

56. *cyàneum*, Rudolph. Perennial, 2–3 in. high, glaucous, lilac above: sts. solitary or caespitose: lvs. opposite, few, entire, glabrous; radical oblong or obovate-oblong, somewhat rosulate; cauline oblong- or oblong-linear: fls. purplish pink, about $\frac{1}{4}$ in. across, in a simple or compound corymbose cyme; sepals lanceolate; petals ovate-oblong. Siberia. Gt. 27:972.

57. *Èwersii*, Ledeb. (*S. azureum*, Royle not Desf.). Perennial, glabrous: st. thick, giving off many trailing or ascending shoots, rather woody at base, 4–12 in. high: lvs. opposite, sessile, about $\frac{1}{2}$ –1 in. diam., suborbicular, cordate, amplexicaul, entire or slightly sinuate: fls. numerous, pink or pale violet, in dense globose cymes; sepals linear-lanceolate; petals oblong-lanceolate; anthers purplish. Siberia, N. India, Kashmir, and Thibet. Gt. 9:295.—Said to be tender, but well worth pot-culture. Var. *turkes-tanicum*, Hort., is said to grow 4 in. high and to have deep violet fls. and furthermore to be hardy in Mass.; little known to gardeners.

58. *stoloníferum*, Gmel. (*S. ibéricum*, Stev. *S. spúrium*, Bieb.). Perennial: barren shoots trailing, glabrous, rooting at the nodes; fl.-sts. ascending, 6 in. high, reddish: lvs. opposite, $\frac{3}{4}$ –1 $\frac{1}{4}$ in. long, spatulate or obovate-cuneate, coarsely toothed above, short-petioled: fls. numerous, $\frac{1}{2}$ – $\frac{3}{4}$ in. across, pink or white, in terminal umbellate cymes, 2 in. diam.; sepals linear-oblong; petals lanceolate; anthers reddish, speckled. Asia Minor and Persia, also escaped in N. Maine and Newfoundland. B.M. 2370. Gn. 27, p. 315. R.H. 1891, p. 523.—*S. spúrium*, Bieb., is maintained as a species by some authorities, but there seem to be no good characters by which to distinguish it. A showy species, common in European gardens and well adapted to rockeries. Var. *coccíneum*, Hort. (*S. spúrium* var. *coccíneum*, Hort.), is offered, in the trade.—The following trade names also appear: *S. spúrium* var. *álbum*, Hort., *S. spúrium* var. *roàeum*, Hort., *S. spúrium* var. *rúbrum*, Hort., and *S. spúrium* var. *spléndens*, Hort.

59. *Nèvii*, Gray. Perennial, caespitose, tufted, glabrous: barren shoots prostrate; fl.-sts. erect, 2–5 in. high: lvs. of barren shoots crowded in terminal rosettes, $\frac{3}{4} \times \frac{3}{8}$ in., alternate, obovate-spatulate, tapering to a short petiole, auricled at the base, sprinkled with pink dots; those of the fl.-sts. scattered, alternate, similar, but appressed: fls. numerous, white, nearly $\frac{1}{2}$ in. across, in forked cymes whose branches are 1–1 $\frac{1}{2}$ in. long and recurved; sepals greenish, oblong; petals lanceolate; anthers brownish purple. Mountains of Va. to Ala. and Ill., but hardy as far north as Mass. B.B. (ed. 2) 2:210.

60. *retúsum*, Hemsl. Shrubby, glabrous: branches thick and fleshy: lvs. alternate, small, about $\frac{1}{2}$ in. long, oblong-oval or spatulate, sessile, flat, fleshy, usually retuse: fls. white, subsessile, in a few-fl'd. cyme; sepals linear-oblong; petals oblong, acute, keeled on the back. Mex.

61. *Cepàa*, Linn.; also spelled *caepium*. Annual, 10–12 in. high, glabrous: sts. tufted, simple or loosely branched: lvs. alternate, $\frac{1}{2}$ – $\frac{3}{4} \times \frac{1}{2}$ in., oblong-spatulate, narrowed to the petiole; cauline opposite, whorled or scattered, narrower: fls. white, $\frac{1}{4}$ – $\frac{1}{2}$ in. across, in a loose many-fl'd. paniculate cyme which has purple-spotted, spreading branches; calyx-tube very short, sepals lanceolate; petals lanceolate, with pink mid-nerve and often a few pinkish spots; anthers purplish. W. and S. Eu.—Cult. specimens are sometimes said to be pink-fl'd.

62. *Anacámpseros*, Linn. (*S. rotundifólium*, Lam.). Perennial, glaucous, evergreen: branches terete, rooting at the nodes; fl.-sts. erect, reddish, about 6–8 in. high: lvs. alternate, orbicular or obovate-obtuse, cordate, auricled, margins reddish: fls. numerous, pale

3590. *Sedum ternatum*. ($\times \frac{1}{4}$)

violet, $\frac{1}{4}$ in. across, in dense, terminal, globose cymes; sepals lanceolate; petals oblong-lanceolate. Cent. Eu. B.M. 118.—Suitable for edging and rockeries, but the fls. are comparatively rarely produced. Var. *Bórderi*, Hort., equals *S. Telephium* var. *Borderi*.

63. *stellatum*, Linn. Annual, glabrous: sts. erect, 3-4 in. high, branched at the base: lvs. of the barren shoots in a rosette, suborbicular, crenate, flat; cauline alternate or rarely opposite, petioled, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, obovate, crenate: fls. reddish or purplish, in lax, few-fl., terminal cymes; sepals lanceolate; petals lanceolate. S. Eu.—Probably rare in cult.

S. Adolphii, Hamet. Perennial: fl.-sts. erect, robust, branched: lvs. alternate, sessile, obovate, lanceolate, or broadly obovate, $\frac{3}{4}$ -1 $\frac{1}{4}$ in. $\times$ 6-7 lines, flat, entire: fls. in a rather dense corymbose cyme; sepals broad-deltoid; petals ovate-lanceolate. Mex.—*S. dliuidum*, Hort., is offered in the trade as a form growing 6 in. high, with white fls.—*S. allantoides*, Rose. Perennial, 8-12 in. high, woody below: lvs. almost at right angles to the st., terete, clavate and somewhat bowed, glaucous: fls. greenish white, in an open terminal panicle; sepals ovate, acute; petals lanceolate, acute. Mex.—*S. atrosanguineum*, Hort., is offered in the trade.—*S. béltum*, Rose (*S. farinosum*, Rose, not Lowe). Perennial plants, at first forming dense elongated rosettes: fl.-st. weak, ascending or spreading: lvs. flat but thickish spatulate: infl. a broad open cyme; petals white, spreading, lanceolate. Mex. In its wild state this species grows on cliffs among mosses. It has been in cult. in Washington since 1906, and deserves a place in every good succulent collection.

—*S. Braunii*, Hort., is offered.—*S. Bróvni*, Hort., is offered in the trade.—*S. calabricum*, Ten., is a name without description applied to some Italian species which is offered in the trade.—*S. coccineum* Hort., not Royle, is a name mentioned in horticulture; possibly it is *S. stoloniferum* var. *coccineum*.—*S. Cöckerellii*, Brit. Perennial, 8 in. or less high, glabrous, branched: basal lvs. not known; cauline lanceolate to oblong-lanceolate, $\frac{1}{2}$ -1 in. long, sessile, acute: fls. white, subsessile, in cymes which are $\frac{3}{4}$ -2 $\frac{1}{2}$ in. diam.; sepals nearly linear; petals linear-lanceolate to linear-oblancheolate; anthers and styles pink. New Mex. This species is in cult., but cannot be placed in the key owing to lack of sufficient data.—*S. crassifolium*, Hort., is offered in the trade.—*S. cristagalli*, Hort., is offered.—*S. crúentum*, Hort., is offered in the trade.—*S. diversifolium*, Rose. Perennial: barren shoots short; fls.-sts. elongated, weak: lvs. of barren shoots flattened ovate, small, rough, somewhat recurved: fls. pale yellow, terminal, solitary, short-peduncled; sepals obtuse; petals ovate, acute or even apiculate. Mex.—*S. Douglasi*, Hook., grows 4 in. high: lvs. lanceolate, $\frac{1}{2}$ - $\frac{1}{4}$ in. long, acute, and has yellow fls.; probably not in cult.—*S. Dúrgidum*, Hort., is offered in the American trade as a compact grower and bright green; not known botanically.—*S. Eichlámi*, Hort., is offered in the trade.—*S. glaucum* var. *aureum*, Hort., is offered as a golden yellow variety; not placed satisfactorily.—*S. grandiflorum*, Hort., is offered as a strong grower with yellow fls.—*S. himalaicum*, Hort., is offered as a form with rich yellow fls.; not known botanically.—*S. Mavedunum*, Hort., is offered as growing 4 in. high: fls. yellow.—*S. murálie*, Hort., is said to have dark lvs. and white fls. with a pink center; not known botanically.—*S. nibeum*, Hort., is offered in the trade.—*S. pallidum*, Bieb. Perennial, glabrous or glandular-pubescent above: sts. usually branched: lvs. semi-terete, linear, rather obtuse: fls. white or rose in a lax branched scorpioid cyme; sepals triangular, acute; petals puberulent, cuspidate. Asia Minor, Persia, and India. Closely allied to *S. hispanicum*. This is the true species but the name has also been applied to several other species and it is uncertain which form is in cult.—*S. pallidum* var. *roseum*, Hort., is in the trade but cannot be satisfactorily identified.

—*S. pruinatum*, Brot. Perennial, glaucous, pruinose: barren shoots 6-8 in. long, trailing and ascending; fl.-sts. erect, 1 ft. high: lvs. in many rows, sessile, more or less terete, glaucous, tips often rose-pink, about $\frac{3}{4}$ in. long, linear-oblancheolate, aristate: fls. bright yellow, $\frac{1}{2}$ in. across, in an umbellate, many-branched, flat-topped cyme; sepals oblong, acute; petals oblong, obtuse. Eu. Closely allied to *S. rupestre* and included in it by some authorities.—*S. rariflorum*, N. E. Br. Perennial: sts. numerous, decumbent, up to 6 in. long, glabrous: lvs. alternate, flat above, slightly convex beneath, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long, linear, acute, green: fls. white, in a lax 2-3-branched infl.; sepals spreading, linear, acute; petals oblong-lanceolate, acuminate. China.—*S. retrovum*, Hort., is offered in the trade.—*S. Sempervivum*, Hort., not Ledeb.—Cotyledon *Sempervivum*.—*S. sexemifidum*, Hort., is offered in the trade; perhaps an error for *sexfidum* which is a synonym of *S. hispanicum*.—*S. spathulatum*, Hort., is a trade name of a species said to grow several feet high, botanically unknown.—*S. speciosum*, Hort., is still offered in the trade, but is unknown botanically. Var. *rubrum*, Hort., is offered in the American trade as growing 6 in. high and having dark red fls. in July. Var. *spléndens*, Hort., is offered as a form growing 6 in. high, with deep red fls.—*S. tectorum*, Scop.—*Sempervivum tectorum*.—*S. turkestanum*, Hort., is possibly a trade error for *turkestanicum* which is a variety of *S. Ewersii*.—*S. undulatum*, Hort., is offered in the trade.

F. TRACY HUBBARD.†

SEEDS AND SEEDAGE. A seed is a ripened embryo, and its integuments and storage supplies, resulting from fertilization in the flower. Seedage is a term used to include all knowledge respecting the propagation of plants by means of seeds or spores. The

word was first used, so far as the writer is aware, in 1887. It is equivalent to the French *semitis*, and is comparable with the words graftage, layerage, and cuttage. See *Spores*.

In general literature and common speech, a seed is that part of the plant which is the outcome of flowering and which is used for propagating the species. In the technical or botanical sense, however, the seed is the ripened ovule. The seed contains an embryo, which is a miniature plant. The embryo has one or more leaves (cotyledons), a bud or growing-point (plumule) and a short descending axis (caulicle). From the caulicle or stemlet, the radicle or root develops. This embryo is a minute dormant plant. Each embryo is the result of a distinct process of fertilization in which the pollen of the same or another flower has taken part. The ovule is contained in the ovary. The ripened ovary is the seed-case or pericarp. The pericarp, with the parts that are amalgamated with it, is known technically as the fruit. In many cases there is only one seed in the fruit; and the seed and its case may adhere and form practically one body. Many of the so-called seeds of horticulturists are really fruits containing one or few seeds. Such are the seeds of beet, lettuce, and sea-kale. The winged seeds of elms, hop-tree (Fig. 3591), and ashes are really fruits containing a single seed. Acorns, walnuts, butternuts, and chestnuts are also fruits; so are grains of corn, wheat, and the "seeds" of strawberry. The keys of maple are double fruits, with two seeds (Fig. 3592). Beans and peas are true seeds; the fruit part is the pod in which they are borne. Seeds of apples and pears are also true seeds, the fruit being the fleshy part that surrounds them.

Germination is the unfolding and the growing of the dormant or embryo plant. The first visible stage in germination is the swelling of the seed. Thereafter the integument is ruptured, and the caulicle appears. When the caulicle protrudes, the seed has sprouted; and this fact is taken as an indication that the seed is viable (Fig. 3593). Germination is not complete, however, until the young plant has made vital connection with the soil, has developed green assimilative organs and is able to support itself (Fig. 3594). See, also, Figs. 3595 and 3596. Seeds that have sufficient life to

3591. Seed-like fruit of hop-tree. (Natural size)

3592. Natural planting of maple seeds.

sprout may still be too weak to carry the process to complete germination. The ideal test for the viability of seeds is to plant them in soil in conditions that somewhat nearly approach those in which they are finally to be planted. This test eliminates the seeds which are very weak and are not able to grow under ordinary

conditions and to push themselves through the soil. The sprouting test made in a specially prepared device, in which all conditions are regulated to a nicety, may be of the greatest value for purposes of scientific study and investigation and for the making of comparative tests between various samples, and the greater the

3593. Sprouting stage.—Castor bean.

sprouting test, the greater the germinating power; but one must not expect that the actual germination will always be as great as the percentage of sprouting. The test for sprouting shows only which seeds are alive. In many cases, the differences in results between the sprouting test in a specially prepared device and the germination tests in well-prepared soil in the open may be as great as 50 per cent. Viability varies with seasons and other conditions. While it is true as a general statement that the older the seed the less the viability, yet the reverse may be true within narrow limits. Sometimes lettuce and melons that germinate only 50 per cent in December, germinate 70 to 80 per cent in April. For a discussion of technical methods of seed-testing, see Vol. II, "Cyclopedia of American Agriculture," and other works.

In order that seeds shall germinate, they must be supplied with moisture and be given a definite temperature. The requisite temperature and moisture vary with the different kinds of seeds, and these factors are to be determined only by experience. Seeds may be planted in any medium that supplies these requisite conditions. Although seeds are ordinarily planted in the ground, such practice is not necessary to germination. They may be planted in coconut fiber, moss, or other medium. However, the ground may supply the requisites for germination, and it also supplies plant-food for the young plantlet when it begins to shift for itself; and, furthermore, the plants are in the position in which it is desired they shall grow. In the case of many seeds, germination is more rapid and certain when the seeds are sown in coconut fiber or other medium, for the conditions may be more uniform. As soon as germination is fairly complete, the plants are transplanted to the soil.

The depth at which seeds shall be sown depends on many conditions. Out-of-doors they are planted deeper than in the house, in order to insure a uniform supply of moisture. A depth equal to twice the diameter of the seed is an old gardeners' rule. This applies well to the

3594. Germination complete.—Castor bean.

sowing of most seeds under glass when the soil is well prepared and is kept moist, but in the open ground three to four times this depth is usually necessary. The finer and moister the soil, the shallower the seeds may be planted, other things being equal. Better results in germination are secured when the seeds are sown in a specially prepared seed-bed. The conditions may then be better, the gardener is able to protect the young plants from cold and from insects and fungi, and he is enabled also to economize time and labor. In transplanting from the seed-bed to the field, the gardener unconsciously chooses only the best plants and thereby the crop is improved. The seed-bed may be in a forcing-house or hotbed, or in the open. If it is in the open, it should be near the buildings, where it can be visited frequently and where water may be applied as needed. If the bed is to be used late in the season when the soil is naturally dry, it is well to cover it the previous spring or fall with a coating of not too rich manure. This retains the mois-

ture, and the leaching from the manure adds plant food to the soil, thereby enabling the young plants to secure an early start. When the seeds are to be sown, the manure is removed and the surface is then in perfect condition. In the handling of young plants in seed-beds, one must take pains that the plants are not too thick and that they do not suffer for light, else they may become "drawn" and be practically worthless. In greenhouses and hotbeds, it is well to handle common vegetables and flower seeds in gardeners' flats (Fig. 3597). These flats are easily handled, and the soil is so shallow that it can be kept in uniform conditions of temperature and moisture. The seeds of some of the finer and rarer kinds of ornamental plants require special treatment. These treatments are usually specified in the articles devoted to those plants. Details of the handling of very delicate seeds are well discussed in the article on *Orchids*; see the article *Palm* and others, and the discussion of propagation of conifers, page 360, Vol. I.

3595. Sprouting stage of Indian corn.

As a rule, seeds germinate best when they are fresh, that is, less than one year old. Some seeds, however, of which those of melons, pumpkins, and cucumbers are examples, retain their vitality unimpaired for a number of years, and gardeners do not ask for recent stock. Seeds of corn-salad should be a year old to germinate well. Very hard bony seeds, as of haws and viburnums, often do not germinate until the second year. In the meantime, however, they should be kept moist. Seeds of most fruit and forest trees should be kept moist and cool, otherwise they lose vitality; yet if kept too moist, and particularly too close or warm, they will spoil. Nuts and hard seeds of hardy plants usually profit by being buried in sand and allowed to freeze. The freezing and the moisture soften and split the integuments. Sometimes the seeds are placed between alternate layers of sand or sawdust: such practice is known technically as stratification.

L. H. B.

Seed-breeding and -growing.

Seed-breeding may be considered from at least two very distinct viewpoints: first, the origination and development of new and improved varieties, either through selection or cross-breeding; and second, the development and raising of truer purer stocks of strains of proved value. See *Breeding of Plants*, Vol. I.

The first, as a rule, seems the most attractive inversely to one's knowledge and experience, but the growing of better and purer strains of the sorts which have proved best suited to one's local conditions and individual requirements is of far greater practical value. An important consideration of success in raising new varieties is the widest obtainable knowledge not only of the varietal forms of the species generally grown, but of the many stocks which at different times and in different locations have been found to be of so little practical value that they have never come into general cultivation. A second requisite is familiarity with the growing habits of the plant, and those of similar species, and the dexterity which can come only through practice in the crossing of the flowers and securing good growth and development of the fruits. There should also be developed a capacity for a quick judgment as to the probable correlation between conspicuous variations with others less discernible by the eye but which may effect the cultural value. Lastly, the development of new varieties of real value can come only through the practice of almost infinite patience which makes one content to throw into the dump thousands upon thousands of plants, many of which had seemed most promising, and to be satisfied if after years of labor one

CIV. Seed-growing in California.—Above, drying and turning lettuce stalks on the sheets. Below, cutting onion heads.

secures but a single variety or marked form of real value to the cultivator.

The second, and perhaps the most important branch of seed-breeding, is the raising of purer strains of stocks of proved value. An illustration of the need of work in this direction can be drawn from a recent trial planting of garden beets in which it was found that practically every root grown from 2-rod plantings of each of 214 samples of seed purchased under distinct varietal names from the most reputable seedsmen of America and Europe could be grouped into not over twenty distinct forms, and the roots so thrown together show as little variation as the crop from any one of the twenty most uniform samples in the trial. Often the only difference between two lots sold under different names would be in the proportion of the roots of each lot that conformed to the same varietal form. It is thought that seed-stocks of most species of garden vegetables would show similar variation, though possibly not to the same degree, and this is not so generally due to carelessness in growing or handling as to the want of adherence on the part of the seed-grower to clear-cut ideals of varietal form. Every plant grown from seed has a certain definite and changeless character which was inherent in the seed from which it was grown and is made up of a balanced sum of different tendencies, potentialities, and limitation of development inherited in different and varying degrees from each of its ancestors for an indefinite number of generations, plus more or less influence from climatic and other conditions effecting the development of the seed-producing plant. Generally the influence of the immediate parent is the dominant one, but not infrequently a characteristic of an ancestor which has been transmitted unexpressed for many generations appears in such strength as to change the whole character of the plant.

Under these conditions, a necessary preparation for the growing of better stocks is the formation of a very clear and comprehensive conception of the exact

varietal character of the stock to be grown, and a rigid adherence to that ideal in the selection of seedling plants from year to year, never giving way to the ever-present temptation to use some superlative individual which differs in any respect from the original ideal of the stock. A most important aid, if not a requisite, for such persistence is the writing out and placing on file for frequent reference the fullest practical description of the exact varietal character of the sort. With this in hand, a few plants which come as near as possible to that ideal are selected, and the seed of each saved separately. The next season samples of each of these lots are planted in a preliminary trial. As they develop, and with the written description of the desired form in hand, they are carefully compared and the lots which most uniformly adhere to the described form are selected. The

3596. Germination complete in Indian corn.

next season the reserved seed of the lots which seemed the best in the preliminary trial are planted in blocks as far as possible from each other, or any plants of the species, and the seed raised used for larger plantation for use as stock seed, in the meantime starting another selection from individual plants to take the place of the first, as it deteriorates. An illustration will show the value of careful selection and the necessity for constant

3597. Gardener's flat, or a shallow box, in which seeds are sown and small plants handled. A good size for a flat is 16 x 20 inches, and 3 inches deep.

renewal of even the purest of stocks. A very carefully bred strain of a variety of watermelon was used to plant a 20-acre field grown for seed. When about three-fourths of the fruit was ripe, several hours were spent in looking over the field for "off" stock and less than fifty fruits were found which should be removed. Fully 75 per cent of the fruits were so near alike that they could not be distinguished from each other. Seed from this field was used for planting seed crops and it was so good that little attention was paid to the stock; as a result, some years later, a crop grown in the same vicinity from seed of the same strain, but several generations removed, instead of less than fifty "off" fruits on 20 acres, had fully 75 per cent of the fruits more or less distinctly "off" and less than 20 per cent were as uniformly ideal of the variety as were 99 per cent of those of the first crop.

What might be termed commercial seed-growing has developed very rapidly in America in the past ten years, and there has not only been an increase in quantity, but an improvement in the varietal quality of the seed grown. Seed dealers having secured, sometimes at great cost, desirable stocks, enter into contracts with farmers located in sections where soil and climate are most favorable for the development of the best qualities of the sort and the securing of a full crop of the seed, to plant a given area and deliver to them the entire seed product. This the farmer does, often with little regard to selection, only taking the requisite pains to guard against contamination and mixture with other crops.

The United States Census of 1910 gives the total valuation of the vegetable- and flower-seed crop grown in the United States in 1909 at \$1,411,013 (see page 3136), but it is thought that the amount actually produced was much larger, seed-dealers and -growers generally being inclined to depreciate the extent and profit of the business in order to lessen competition. Since then the amount grown and listed has increased materially, an estimate by a very experienced dealer of the area devoted to vegetable-seed crops in 1915 being as follows:

	Acrea
Seed beans.....	50,000
Cabbage for seed.....	2,000
Sweet corn.....	15,000
Cucumbers.....	15,000
Onions.....	2,600
Muskmelons.....	6,000
Watermelons.....	6,000
Garden peas.....	50,000
Radish.....	4,000
Tomatoes.....	50,000

This is the estimated area contracted for by growers especially for seed, but in the case of many crops, such as melons and peas, the amount of seed grown is greatly increased by crops which were originally planted with the intention of selling them as green vegetables, but which because of market conditions are allowed to ripen and are harvested and sold as seed.

WILL W. TRACY.

The seed trade of America.

The history of the seed business in colonial times is largely one of importation from Holland and England, when small hucksters carried a few boxes of popular seeds with an assortment of drygoods, foodstuffs, or hardware. Corn, barley, peas, onions, fruits, and vegetables, necessities in fact for direct use, first claimed the attention of the colonists. Toward the end of the eighteenth century we begin to find references to the saving of stock seeds, and in the newspapers of the day are a number of advertisements of shopkeepers who dealt in seeds. Agricultural seeds were an article of commerce as early as 1747 (Pieters), clover, onions, beans, peas, carrots, cabbage and cauliflower, and others, being raised for seed in the colonies at that time, though chiefly imported. At that time Boston did most of the business. Among the earliest advertisers of seeds for sale were Nathaniel Bird, 1763, a book-dealer of Newport, R. I.; Gideon Welles, "on the Point," 1764; Samuel Deall, a dealer in general merchandise in New York in 1776; William Davidson of New York in 1768, while in Philadelphia, in 1772, we find one Pelatiah Webster advertising clover and duck-grass seed; James Loughhead, "colly-flower" seed in 1775, while David Reid kept a general assortment.

It was not until the opening of the nineteenth century that America began to find that seeds could be grown here as profitably as they could be imported. Grant Thorburn, in New York, and David Landreth, of Philadelphia, seem to have been the largest dealers at that time. Thorburn's was perhaps the first business of importance devoted entirely to stock seeds, although this honor is disputed by the descendants of David Landreth. Thorburn, in his autobiography, says that he began his business by buying out the stock of one George Inglis for \$15, Inglis agreeing to give up the market and to devote himself to the raising of seeds for Thorburn. This is but one of many small beginnings from which has grown a trade which now amounts to many millions; and this relation between seedsmen and growers is largely typical of relations which have obtained in the trade ever since.

With the development of the railway and the postal service the business grew rapidly, new land was found suitable for different varieties of seed, and a letter could carry to the countryman the garden seeds for his yearly consumption. There is probably no trade which has been more widely benefited by cheap postage and improved mail facilities, but of late years the distribution by Congressmen has tended to negative this benefit. The originally beneficent distribution of free seeds to pioneers and needy settlers was a form of agricultural encouragement against which there could be no criticism, but it has degenerated into an abuse, which is estimated to have taken a trade of some \$4,000,000 during the past two or three decades out of the hands of the men who have built up the business.

Grant Thorburn's catalogue of 1822 was the first to be issued in pamphlet form, and it was the pioneer of the many finely and carefully illustrated catalogues with which we are familiar today. These catalogues have been largely instrumental in facilitating the specialization of the industry and its subdivision in the hands of the country dealer, who buys seeds at wholesale, combining as they do the most complete lists and illustrations of varieties with directions as to methods, con-

ditions, and seasons for planting. They are distributed in hundreds of thousands. Up to 1844 the wording on the bags was written by hand, a laborious and expensive process, which of itself is an indication of the small volume of the trade at that date.

With regard to the export of seeds, A. J. Pieters' admirable report for 1899 in the Yearbook of the Department of Agriculture may be taken as the best information up to that date, and it indicates the development of the business in its earlier years. He says in part: "The statistics of exports date from 1855, and no separate records of imports of seeds were kept before 1873. Clover and grass seeds, especially timothy, have always taken the lead in the seed export trade, and until recent years garden seeds have not been a considerable factor in the total values. In 1825 some 10,000 bushels of clover seed were exported to England within a few months. How long this trade had existed we do not know. From 1855 to 1864 there is no record of any seeds exported except clover, but the value of exports increased from \$13,570 in 1855 to \$2,185,706 in 1863, the war apparently having no effect on the trade. The total value of the clover seed exported during this period aggregates \$5,393,663. In the ten years ending with 1880, clover seed was not separately entered except in the last year, but the total exports of seeds amounted during that period to \$20,739,277. The aggregate was increased by more than \$3,000,000 before the end of 1890. From 1891 to 1898 there has been a slight reduction in the average annual value of seed exports and also in the amount of clover and timothy seed sent abroad." The value of "flower and vegetable seeds" reported in the Thirteenth Census (for 1909) is \$1,411,013 as against \$826,019 for 1899, an increase of above 70 per cent. Aside from this are grass seed to a value of \$15,137,683 in 1909, not including beans, peas, and miscellaneous seeds. "Other grains and seeds" altogether (aside from "cereals") had a value in 1909 of \$97,536,085. (See Tracy, page 3135).

The importation of staple garden seeds had largely decreased by 1870, and with the exception of a few staples in agricultural and flower seeds, America may be said to have become to a great extent self-supplying. The greatest development of this industry has taken place since the close of the war. In 1878 J. J. H. Gregory estimated that there were in all 7,000 acres devoted to garden seeds, while the census of 1890 showed that there were 596 seed-farms, containing 169,850 acres. Of these farms, 200 were established between 1880 and 1890, and it is likely that about 150 more were started during the same period. The census returns, however, do not give the actual acreage devoted to growing seeds. As many seeds are grown by those not regularly in the business, it is probable that census returns as to acreage are under rather than over the mark. The statistics available in the United States Census are very imperfect, partly owing to the lack of a continuous system in presentation, both in the returns of home industry and also in custom-house returns, but chiefly to the reluctance of seedsmen and growers to make public the results of their business methods or even the methods themselves.

The following table will give as close an estimate as can be made of the present annual cost of the chief staple garden seeds handled in America:

Garden peas.....	\$1,500,000
Garden beans.....	400,000
Onion seed.....	500,000
Lettuce seed.....	250,000
Cabbage seed.....	200,000
Sweet corn.....	300,000
Tomato seed.....	150,000
Radish seed.....	125,000
Turnip seed.....	60,000
Beet seed.....	25,000
Celery seed.....	6,000
Miscellaneous seeds and flower seeds.....	250,000
Sweet peas, flowering.....	200,000
Probable invoice cost of imported garden seeds.....	2,000,000

The seeds usually offered by seedsmen in their catalogues, or in the seed-stores throughout the country, are secured from various parts of the world, and the seedsmen who sell seed at retail to the planter direct seldom grows his own seed, although some of the larger firms now conduct seed-farms on which they grow certain specialties, and most of them conduct trial and experimental grounds.

The wholesale seed business is divided into two distinct lines, one of so-called grass-seed dealers, who buy from the farmers such things as grass seeds, clover seeds, and farm seeds used for planting large areas; the other line is the general seed-dealer who carries a limited stock of grass seeds, clover seeds, and the like, and specializes on vegetable seeds and flower seeds. He is usually not a grower of seed, but buys from seed-growers who specialize on a few things.

A large part of the vegetable and flower seed used in America is imported from England, France, Germany, Holland, and Denmark, especially such things as beets and mangels, cabbage and cauliflower, turnip and rutabaga, and the small flower seeds. In Germany, the seed-growers usually own or lease their own seed-farms, while in other countries, especially France, much of the seed-growing is conducted on the subcontracting plan, the grower keeping an agent in a certain locality and letting out small contracts with the farmers. The finer vegetable seeds and flower seeds, as well as the larger lines, are grown in this way.

In America, the smaller vegetable seeds and sweet peas are grown principally in California, where the growers own or lease their seed-farms, and practically all of their capital is invested in the seed business. What are considered the "smaller vegetable seeds" and "California specialties" are carrot, endive, leek, lettuce, onion, parsnip, parsley, radish, salisfy, and flowering sweet peas. The preëminent California specialties are lettuce, onion, and sweet pea seed. There are no less than 5,000 acres, principally in the coast counties of central California, devoted to these three things. Pole beans, culinary peas, and some vine seeds are also produced in central California. These are grown on the subcontracting plan, much as in other places. Peas are now grown largely in Utah, Idaho, and Montana, as well as in Wisconsin, Michigan, and northern New York. Sweet corn and vine seeds are grown largely in Nebraska, northern Ohio, New York and New England. Watermelon seed is grown largely in the South; also okra. The best cabbage seed is produced in Long Island and to some extent in the country about Puget Sound in Washington. Pepper and eggplant, and some tomato seeds, are grown in New Jersey, and tomato seed is also grown in Michigan and California. Various other items are grown in greater or less quantities in various sections, such as beet and parsnip in New England, radish in Michigan, turnip in Pennsylvania, but the main sources of supply of these last-named articles are the European countries previously mentioned.

Seed-growers who subcontract their crops, usually operate large farms for the production of their stock seeds, where they do their selecting and developing and where they grow the seeds which they send out to the farmer to produce crops for them. Such crops as are subcontracted are "rogued" and inspected throughout the season by the grower's agent. Seed-growing, as it affects vegetable and flower seeds, is conducted more or less scientifically and represents a very high state of intense farming, perhaps the highest known out-of-doors.

Seeds must be produced in regions where they can be grown not only profitably on account of climatic conditions and abundant labor, but also in sections where the quality can be maintained. Climates with a cold winter are usually required for biennial crops, such as carrot, beet, onion; when grown in California, the strains must be often renewed. Certain other crops

require a dry summer climate, such as lettuce and sweet peas; other kinds require a moist or wet summer climate, as cabbage and cauliflower.

Many seed-growers now specialize on one or two lines, and there are large growers who raise nothing but tomato; others nothing but cabbage; others who raise only sweet corn; others field corn; and others confine themselves to watermelon. Owing to the frequency of crop failures in seed production, as in other farm crops, most seedsmen contract with at least two sources of supply and usually both widely separated.

Commission box assortments comprise one of the principal methods pursued in America for the sale of seed. This plan places with merchandise and grocery stores an assortment of staple seeds in flat papers and cartons. These assortments are usually sold on commission, but some firms sell the assortments outright. The boxes and unsold seed are collected every year and returned to the home firm, where the papers are torn, the seed tested and repapered with a proportion of new seed. Some twenty firms are engaged in this line of seed distribution, and one firm has nearly 150,000 customers to whom it consigns these assortments. Many of the merchants who take these commission boxes also carry small lots of staple seeds in bags to sell in bulk and are therefore seed merchants in a small way. They usually rely for their base of supply on the seed-houses who consign them the box.

Dealers in garden seeds are also large dealers in flowering bulbs, such as hyacinths, tulips, narcissi, crocus, and the like. These are chiefly imported from Holland, south of France, Italy, and Japan.

The trade is divided into the main branches of garden and flower seeds and bulbs, and agricultural seeds. The latter is practically a business by itself, devoted to such seeds as blue-grass, timothy, clover, red-top and alfalfa, some of which are exported or imported as the exigencies of the season's product demand.

Flower seeds are subjected to no import duties, while on garden seeds there is a tariff figured on a specific basis. It is a moot point whether this tariff at the present time operates to the advantage of the trade, the principal seedsmen being generally of the opinion that it tends to stimulate over-production in this country.

The main business of the country is in the hands of about 150 firms, but practically every groceryman in country towns and villages carries a stock during the spring season. These men, however, deal as a rule with the larger houses, and constitute the principal class of middlemen for retail trade.

The seed-growing and merchandizing industry is represented by the American Seed Trade Association.

J. M. THORBURN & Co.

C. C. MORSE & Co.

SEEMÁNNIA (named for Berthold Seemann, 1825-1871). *Gesneriaceæ*. Strigose-pubescent perennial herbs with rhizomes, suitable for the warmhouse: sts. stout, simple: lvs. verticillate, in 3's or 4's, very short-petioled, frequently canescent below; the upper ones reduced to bracts: pedicels solitary in the axils: fls. red-purple; calyx-tube turbinate, adnate, lobes 5, narrow; corolla-tube bent downward, broadly and obliquely subcampanulate, the limb with very short erect-spreading lobes; disk annular, undulate and not divided; ovary almost entirely inferior: caps. nearly inferior.—Two species, *S. Amer. S. silvatica*, Hanst. (*S. iernifolia*, Regel). Plant 3-4 ft. high: lvs. 3-4 in a whorl, very shortly petioled: fls. solitary, bright scarlet: calyx with 5 narrow lobes; corolla short-gibbous at base. Winter. Peru. Gt. 4, p. 182.

SELAGINÉLLA (diminutive of Latin *Selago*, old name of a club moss). *Selaginellaceæ*. CLUB MOSS. A large group of mostly tropical plants with small scale-like leaves and of diverse habit, ranging from minute prostrate annuals to erect or even climbing perennials.

Easily recognized by the production of two kinds of spores—powdery microspores from which the male prothallus arises and larger microspores produced 4 in a sporangium just within the axil of the terminal lvs. of the st. which often form a 4-angled spike. In all our cult. species the lvs. are in 4 ranks, the 2 upper smaller and pressed against the st., giving it a flattened appearance. Selaginellas are graceful fern-like greenhouse plants, often known to gardeners as lycopodiums. The botany of the genus is in an uncertain state, both as to nomenclature, and the limits of species. They are plants of the Pteridophyta or fern allies.

Selaginellas are favorite plants in every good conservatory, being greatly admired for their feathery moss-like foliage. They have various shades of green, and some of them are remarkable for metallic and iridescent tints, especially bronze and bluish colors, the latter being very unusual among plants in general. *S. Willdenovii* is a very choice large-growing species of the bronze and blue class. Another is *S. uncinata*, often called "rainbow moss." Selaginellas are often grown for their own sake as specimen plants, but they are also very commonly used as edging for greenhouse beds, for covering unsightly spots under the benches, and for hiding the surface soil of large tubs, orchid pots, and the like. (See Fig. 3598.) They are also delightful subjects for table decoration when grown in pans or jardinières. For this purpose a well-grown selaginella should be a dense compact mass of fluffy and feathery green, not a weak thin straggling plant, as compared in Figs. 3599 and 3600. Selaginellas are also employed in bouquets of flowers, fronds being used for "green" instead of asparagus or fern. Occasionally a fancier of the more difficult species grows a large specimen in a Wardian case for exhibition. In general, selaginellas are of easy culture. As a rule they prefer shade and moisture and are somewhat tender in foliage compared with some of the commonest of commercial ferns. *S. denticulata*, *S. Kraussiana*, *S. Martensii*, and some other

sometimes requires about nine months from the making of cuttings until the young plants are ready for potting. Fill regular fern-boxes with fern soil, adding one part in five of sand, and press firmly. Choose mature fronds of the *S. Emmeliana*, cut them into pieces half an inch long, scatter thinly over surface of soil, and put just enough finely screened soil on top of the cuttings to attach some small portion of them to the soil. Water thoroughly, cover with glass, and place in a temperature of 70° F. In this condition they will soon form roots and little plants at almost every joint. When sufficiently large they should be separated and transplanted singly an inch apart into boxes, where they may be left until large enough to be potted. The following list of selaginellas for special and general purposes is not designed to be complete, but merely suggestive. For commercial purposes, *S. denticulata*, *S. Kraussiana*, *S. Martensii*, and *S. Emmeliana*; for carpeting the soil, *S. denticulata*; for table decoration, *S. Emmeliana* and *S. Martensii*; for cutting, the commercial kinds; for veranda-boxes, *S. Braunii*; for bronze and blue colors, *S. Willdenovii* and *S. uncinata*; for specimen plants and exhibitions, *S. Braunii*, *S. Lyallii*, *S. viticulosa*, *S. Wallichii*, and *S. Willdenovii*. Also the following, which are generally considered more difficult subjects: *S. atroviridis*, *S. hæmatodes*, and *S. molliceps*; for curiosity, *S. serpens* and *S. lepidophylla*. The curiosities of the genus call for special mention. *S. serpens* is remarkable for its changes of color during the day. In the morning the foliage is bright green; during the day it gradually becomes paler as though bleached by the light; toward night it resumes its lively green hue again. For *S. lepidophylla*, see *Resurrection Plants*. The following species also deserve a few running notes: *S. Braunii* is an old favorite which is often incorrectly labelled *S. Willdenovii* in collections. Its branches, or "foliage" in the popular sense, are exceptionally tough and wiry for the genus. Variegated forms appear in *S. Martensii*, *S. Kraussiana*, and *S. involvens*, the last-named species being prolific in singular forms. *S. viticulosa* is better adapted for use as a pot-plant than for mingling in a fernery, because of its strong-growing erect fern-like habit. The branchlets are thrown up from creeping stems and do not root readily, so that this species is usually propagated by division or spores. (W. H. Taplin and N. N. Bruckner.)

3598. A selaginella used to cover the soil of an orchid pot.—*S. denticulata*. ($\times \frac{1}{4}$)

commercial favorites may be rapidly propagated without any preliminary treatment in the cutting-bench. Cuttings of these species about an inch and a half long may be inserted directly into small pots of light sandy soil, placed in a shady position. Syringe them lightly three or four times a day for a week, at the end of which time they will take root. They will soon grow into salable plants. The popular *S. Emmeliana*, which is generally considered by florists a variety of *S. cuspidata*, requires different treatment. It is much slower and

KEY TO THE SPECIES.

- A. Lvs. all similar, many-ranked: native species. 1. *rupestris*
- AA. Lvs. 4-ranked, of two sorts, forming an upper and a lower plane: mostly hothouse exotics.
 - B. Foliage of the spikes uniform.
 - c. Main st. decumbent, usually rooting throughout.
 - d. Plants perennial: lvs. firm.
 - E. Sts. continuous, i. e., without joints.

- F. Branches $\frac{1}{8}$ in. or less wide:
sts. 6-9 in. long..... 2. denticulata
3. serpens
4. patula
- FF. Branches $\frac{1}{4}$ in. or more
wide: sts. 1-2 ft. long... 5. uncinata
6. plumosa
7. concinna
8. stolonifera
9. Kraussiana
- EE. Sts. articulated..... 10. Cunninghamii
11. brasiliensis
12. apus
13. albo-nitens
- DD. Plants annual; lvs. and st. weak
and flaccid 14. atroviridis
15. californica
16. Martensii
- CC. Main sts. ascending, branched
nearly or quite to the base.
- D. Roots confined to the lower half
of the sts.
- E. Plants perennial, with con-
tinuous sts.
- F. Color of lvs. and st. pale or
bright green..... 17. rubella
18. Poulteri
- FF. Color of lvs. dark green, be-
coming red: st. reddish
brown 19. involvens
20. lepidophylla
21. cuspidata
- EE. Plants annual..... 22. Emmeliana
- DD. Roots confined to the base of the
sts.
- E. Sts. crowded in rosettes, curl-
ing closely when dry..... 23. Wallichii
24. Victoriz
- EE. Sts. 6-12 in. high, not curling
in rosettes 25. gracilis
26. Lobbii
- EEE. Sts. elongated (2 ft. or more),
not crowded.
- F. Lvs. equal-sided at base... 27. Willdenovii
- FF. Lvs. produced on upper
side at base 28. grandis
- CCC. Main sts. climbing..... 29. viticulosa
- CCCC. Main sts. erect, the branches con-
fined to the upper portion, naked
below.
- D. Sts. not jointed.
- E. Color of sts. straw-colored, or
at most only pink-tinted.
- F. Lvs. long, the ultimate divi-
sions of st. $\frac{1}{2}$ - $\frac{3}{4}$ in. wide... 30. caulescens
- FF. Lvs. shorter or minute; the
ultimate divisions of st.
 $\frac{1}{5}$ - $\frac{1}{6}$ in. wide.
- G. Plants usually less than
a foot high..... 31. Braunii
32. flabellata
33. Vogeli
34. Lyallii
- GG. Plants 1-2 ft. high..... 35. erythropus
36. hematodes
- EE. Color of sts. crimson..... 37. geniculata
- DD. Sts. jointed in lower two-
thirds..... 38. cordifolia
39. molliceps
- BB. Foliage of spike of two kinds, the
smaller forming a lower plane,
the larger an upper.....

1. *rupéstris*, Spring. A small, rock-loving perennial, with branching sts. 4-5 in. long, many-ranked lvs. ending in a white awn, and square, 4-angled spikes. Native of the eastern half of the U. S., but replaced by many allied species in the Rocky Mts. and on the Pacific coast. The writer has separated 6 of these and Dr. Hieronymus, at Berlin, has also characterized 10 others.

2. *denticulata*, Link. Fig. 3598. Sts. less than 6 in. long, matted: lvs. of the lower plane slightly spaced, denticulate, cordate on the upper side at base and imbricated over the st.; lvs. of upper plane cuspidate.

Medit. region throughout.—Trade names are vars. *aurea* and *foliis variegatis*.

3. *serpens*, Spring. Sts. 6-9 in. long, trailing, bright green, copiously branched: lvs. of lower plane crowded, obtuse, spreading, ciliated at the rounded base; lvs. of upper plane obliquely oblong, acute. W. Indies.—Long in cult.

4. *pátula*, Spring (*S. sarmentosa*, A. Br.). Sts. slender, trailing, pale green, 6-9 in. long, with long, tail-like tip, and fewer short pinnate branches: lvs. of lower plane crowded, erect-spreading, oblong-lanceolate, somewhat acute; lvs. of upper plane one-third as long, acute. Jamaica.

5. *uncinata*, Spring (*Lycopodium cæsi* and *Selaginella cæsia*, Hort.). Sts. 1-2 ft. long, extending in a somewhat naked tip beyond the branches, doubly grooved above, with short, alternate branches: lvs. thin, blue-green, with a distinct midrib, slightly more produced on the upper side; lvs. of upper plane cuspidate, much imbricated. China.—In 1893 John Saul offered "*S. cæsia arborea*" with the remark that *S. lævigata* was a synonym thereof.

6. *plumosa*, Baker. Sts. 6-12 in. long, flat above, often forked near the base: lvs. of lower plane close, bright green, much more produced on upper side of midrib, ciliated on both sides at base; lvs. of upper plane half as long, ovate, much imbricated. India, Ceylon, China, Malay Isls.

7. *concinna*, Spring (*S. serrulata*, Spring). Sts. 1 ft. or more long, copiously pinnately branched, with more or less fan-shaped compound branches: lvs. of lower plane crowded, bright green, glossy, much dilated and rigidly ciliate on the upper side at base; lvs. of upper plane one-third as long, long-cuspidate, much imbricated. Mascarene Isls.—Var. *foliis variegatis*, Hort., is cult.

8. *stolonifera*, Spring. Sts. a foot or more long, with a more or less naked tip, angled above and below, with short, compound branches: lvs. of lower plane closely set, rigid, acute, short-ciliate and minutely auricled at base. W. Indies.

9. *Kraussiana*, A. Br. Sts. 6-12 in. long, flat on the back, rounded on the face, copiously pinnate, with compound branches: lvs. of upper plane spaced on the branches and main st. acute, slightly imbricated over the st.; lvs. of upper plane obliquely ovate, acute. Afr., Madeira.—*S. Brownii*, Hort., is a dwarf form from the Azores. Vars. *aurea* and *variegata* are American trade names.

10. *Cunninghamii*, Baker. Sts. copiously pinnate, the lower branches compound: lvs. of lower plane ovate or oblong, cordate and very unequal-sided at base, much imbricated over the st.; lvs. of upper plane distinctly cuspidate. Brazil.

11. *brasiliensis*, A. Br. Sts. copiously pinnate, the lower slightly compound: lvs. of lower plane mostly spaced, acute, cordate at base, ciliate and imbricated over the st.; lvs. of upper plane half as long, cuspidate. Brazil.—Similar to preceding, but with longer lvs.

12. *apus*, Spring. Sts. 1-4 in. long, angled above, with short, simple or forked branches: lvs. of lower plane pale green, serrulate but not ciliate, cordate on the upper side; lvs. of the upper plane ovate. Canada to Texas.—*Lycopodium densum*, cult. at the Harvard Botanic Garden, is said to belong here.

13. *albo-nitens*, Spring. Sts. slender, trailing, the lower branches slightly compound: lvs. of lower plane spaced on main st., short-ciliate, bright green; lvs. of upper plane one-third as long, cuspidate. W. Indies.

14. *atroviridis*, Spring. Sts. 6-12 in. long, ascending, doubly grooved above: lvs. of lower plane spuriously 3-nerved, firm, broadly rounded; lvs. of the upper plane half as long, long-cuspidate, much imbricated. India.

15. *californica*, Spring. Sts. 4-6 in. long, 4-angled, copiously pinnate: lvs. of lower plane ovate, minutely cuspidate, denticulate on the upper side at the base; lvs. of the upper plane very small, ovate-oblong. Said to come from Low. Calif. but not known at Kew and doubtfully in cult. in this country.

16. *Martensii*, Spring. Fig. 3599. Sts. 6-12 in. long, flat or rounded below, angled above: lvs. of lower plane oblong-lanceolate, serrulate but not ciliate, slightly imbricated over the st. at base; lvs. of upper plane obliquely oblong, long-cuspidate. Mex.—Exists under many varieties in cult.

17. *rubella*, Moore. Sts. 1 ft. long, somewhat erect in habit, reddish brown, with 2 grooves on the upper face: lvs. of lower plane dark green, becoming reddish with age, obtuse or obscurely cuspidate, ciliated and imbricated over the st. at the upper side of base; lvs. of upper plane ovate-cuspidate. Native country not known.—Has been in cult. since 1870. Var. *variegata*, Hort., is cult.

18. *Pöulteri*, Hort. Veitch. Sts. densely tufted, slender, suberect, 2-3 in. long, 3-4 times dichotomously forked: lvs. of lower plane spaced, suborbicular, obtuse, bright green; lvs. of upper plane nearly as long, but ovate and acute. Azores.

19. *invólvens*, Spring. Sts. densely tufted, 2-6 in. long, deltoid, branched nearly to the base: lvs. of lower plane crowded, ovate, with a distinct cusp, bright green, thick, rigid, serrulate on both margins; lvs. of upper plane nearly as long, ovate-lanceolate, cuspidate. Japan to India and the Philippines.

20. *lepidophýlla*, Spring. RESURRECTION PLANT. Sts. 2-4 in. long, densely tufted, spreading in a close spiral so as to form a flattish expanse, curling closely into a ball when quite dry: lvs. of lower plane oblique, obtuse, minutely ciliated, green on the face, paler below; lvs. of upper plane nearly as long, obliquely ovate, obtuse. Texas and Mex. to Peru.—Often sold dry under the name of "resurrection plant" (which see), as the absorption of water will cause the ball with a dull brown exterior to expand and show its bright green upper face of the sts. long after the plant is dead.

21. *cuspidata*, Link. Sts. densely tufted, 6 in. or more long, branched nearly to the base, with copiously compound branches: lvs. of lower plane obliquely ovate, cuspidate, dilated and ciliated on the upper side at the base, pale green edged with white; lvs. of upper plane

lets narrower and minutely spinulose; lvs. of upper plane raised above those of the lower one-half as large, spinulose-serrulate, short-cuspidate. S. Amer. (?)—Named for Th. Emmel, a German gardener. Var. *aurea* is a yellow form. This species and its variety are most commonly seen in the American trade. They require a constant supply of moisture. If allowed to dry, the tips of the fronds turn brown and do not recover.

23. *Wállichii*, Spring. Sts. 2-3 ft. long, with lanceolate branches and simple crowded branchlets: lvs. of lower plane crowded, smaller toward the end of the pinnules; lvs. of upper plane one-fourth as long, cuspidate: spikes $\frac{1}{2}$ -1 in. long. India and the E. Indies.—Highly ornamental.

24. *Victória*, Moore. Sts. 3-4 ft. long, with lanceolate-deltoid, caudate branches, with the lower branchlets forked or slightly pinnate: lvs. of lower plane crowded, a line long, truncate at base and obscurely petioled; lvs. of lower plane one-fourth as long, short-cuspidate: spikes 1-2 in. long. Borneo and Fiji Isls.

25. *grácilis*, Moore. Sts. 2-3 ft. long, somewhat roughened, with lanceolate branches and simple branchlets: lvs. of lower plane ovate-falcate, adnate to st. on lower side at base; lvs. of upper plane ovate-lanceolate, cuspidate. Polynesia.

26. *Lóbbii*, Moore (*S. cognata*, Hort.). Sts. 3-4 ft. long, with lanceolate-deltoid branches and contiguous simple or forked branchlets: lvs. of lower plane oblong-lanceolate, acute, bright green, truncate at base; lvs. of upper plane one-third as long, obliquely ovate, cuspidate. Borneo and Sumatra.

27. *Willdenovii*, Baker. Sts. reaching a length of many feet, with spreading deltoid branches and much compound branchlets, the ultimate short and contiguous: lvs. of lower plane crowded, ovate or oblong, tinted with blue, obscurely petioled; lvs. of upper plane one-third as long, obliquely oblong, not cuspidate. India and the E. Indies.

28. *grándis*, Moore. Sts. $1\frac{1}{2}$ -2 ft. long, branched above: lvs. of lower plane crowded, lanceolate, acute, rather firm; lvs. of upper plane one-third as long, ascending, much imbricated. Borneo.

29. *viticulôsa*, Klotzsch. Sts. with deltoid 2-3-pinnate branches: lvs. of lower plane ascending, acute, short-ciliated and much imbricated over the st.; lvs. of upper plane one-third as long, obliquely ovate, cuspidate. Cent. Amer.

30. *caulêscens*, Spring (*S. amêna*, Hort.). Sts. stiff, erect, the short final branchlets curling when dry: lvs. of lower plane crowded, ovate, falcate, bright green; lvs. of upper plane one-third to one-fourth as long, cuspidate. Japan, China, and E. Indies. Var. *argêntea*, Hort., is advertised.

31. *Braûnii*, Baker. Sts. deltoid and flexuous above, with deltoid erect-spreading pinnæ, the pinnules short, deltoid and spaced: lvs. of lower plane ovate-rhomboid, usually revolute at both edges; lvs. of lower plane short-cuspidate. W. China.

32. *fiabellâta*, Spring. Sts. erect, deltoid, decomposed, with contiguous final branchlets: lvs. of lower plane obliquely ovate, acute, broadly rounded and ciliated at the base; lvs. of upper plane obliquely ovate, cuspidate. Widely distributed in tropical regions.—One of the forms of this is cult. as *S. crispa*, Hort.

33. *Vögellii*, Spring (*S. africâna*, A. Br. *S. Pervillei*, Spring). Sts. decomposed above, the lower pinnæ deltoid, petioled, 3-4-pinnate: lvs. of lower plane lanceolate, ascending, often revolute on both edges, truncate at base; lvs. of upper plane minute, strongly cuspidate. Afr.

34. *Lýallii*, Spring. Sts. deltoid above, the lower pinnæ bipinnate, the final divisions $\frac{1}{2}$ -1 in. long, $\frac{1}{8}$ - $\frac{1}{6}$

3599. Poorly grown specimen of club moss, unsuitable for table decoration.—*Selaginella Martensii*. ($\times \frac{1}{4}$)

nearly as long, obliquely ovate, cuspidate. Cuba and Mex. to Venezuela.—A plant occurring under the horticultural name *Lycopodium cordifolium* has the st. a foot or more long and simple in its lower part, and doubtless represents a distinct species.

22. *Emmeliâna*, Hort. Fig. 3600. Sts. 6-12 in. high, the primary branches ascending, bipinnate: lvs. of lower plane close, obliquely ovate, those of the branch-

in. wide: lvs. of lower plane oblong-lanceolate, falcate, acute; lvs. of upper plane minute, acute. Madagascar.

35. *erythropus*, Spring. Sts. under a foot long, deltoid and decomposed above, the lower pinnae 3-pinnate, the ultimate divisions $\frac{1}{2}$ – $\frac{1}{3}$ in. wide: lvs. of lower plane oblong-lanceolate, acute, strongly ciliated; lvs. of upper plane one-half as long, cuspidate. Trop. Amer.—*S. setosa*, Hort., is said to be a starved form.

36. *hæmatodes*, Spring (*S. filicina*, Spring). Sts. 1–2 ft. long, the deltoid pinnae 3–4-pinnate, the ultimate

3600. Well-grown specimen of *Selaginella Emmeliana*. Suitable for table decoration. ($\times \frac{1}{4}$)

divisions $\frac{1}{8}$ – $\frac{1}{6}$ in. wide: lvs. of lower plane ascending, oblong-rhomboid, acute, dilated on upper side at base, not ciliated; lvs. of upper plane minute, cuspidate. Venezuela to Peru.

37. *geniculata*, Spring (*S. elongata*, Kl.). Sts. 2–3 ft. long, decomposed, with lower pinnae 3-pinnate, the divisions ascending and pinnately arranged: lvs. of lower plane ovate, acute; lvs. of upper plane one-third as long, ovate-lanceolate. Costa Rica to Peru.

38. *cordifolia*, Spring (*S. cordata*, Kl.). Sts. trailing, a foot long, with short branches often ending in whip-like tips: lvs. of lower plane acute, pale green, ciliated on the upper edge, dilated and subcordate; lvs. of upper plane ovate-lanceolate, cuspidate. W. Indies.

39. *mölliceps*, Spring (*S. rubricaulis*, A. Br.). Sts. erect, 6–9 in. long, bisulcate above, much compound: lvs. of lower plane oblong-lanceolate, dark green, very unequal-sided, serrulate on the upper edge; lvs. of upper plane one-half to one-third as long, ovate or ovate-lanceolate, cuspidate. Afr.

The following American trade names can not be satisfactorily accounted for as species: *S. acutis* is said to be one of the most important commercial species cult. in Amer.—*S. circinata* is cult. at Harvard Botanic Garden.—*S. Lageriana* was intro. from Colombia and probably belongs to species already described from that country. It is said to be a very light green plant and a strong grower, whereas *S. Pitcheriana* is of dwarfer habit and with sts. and under surface of fronds red and upper surface dark green.—*S. Mandiana* is a recent intro. by W. A. Manda which can not be satisfactorily placed.—*S. paradoxa*. Offered by John Saul, 1893.—*S. Pitcheriana*. Consult *S. Lageriana*. Colombia.—*S. rubicunda* and *S. triangularis* were offered by Saul in 1893.—*S. umbræa*. Once cult. by Pitcher & Manda, of the United States Nurseries.

L. M. UNDERWOOD.
R. C. BENEDICT.†

SELÉNIA (probably from the Greek *moon*; said to refer to the round seeds). *Cruciferae*. Small annual herbs sparingly grown in gardens: lvs. pinnatisect: racemes terminal, leafy: fls. yellow; sepals spreading,

colored, subequal; petals erect: silique stipitate, oval berry much compressed or turgid, acute at the base, valves reticulate.—Three species, N. Amer.

åurea, Nutt., is a hardy annual of the mustard family, a native of the U. S. from Ark. and Texas to the base of the Rockies. It is not known to be cult. in Amer., but it seems to be one of the prettiest of our few native ornamental crucifers. It has small yellow fls. about $\frac{1}{2}$ in. across, each of the 4 petals having a central band of red. It is also interesting for its finely cut foliage and its flat pods through which the seeds may be vaguely seen, as in the case of *lunaria*, or "honesty." It grows about 9 in. high. B.M. 6607.

F. TRACY HUBBARD.†

SELENICEREUS (*moon goddess and cereus*). *Cactaceæ*. Cacti with slender trailing hanging or climbing sts., more or less epiphytic: ribs several, usually low, with closely set areoles bearing small short or acicular spines: fls. large, nocturnal, fragrant; ovary and fr. covered with clusters of small spines often accompanied by long hairs.—More than 20 species are known. This genus contains a number of easily grown species which are great favorites in cult. on account of the great size and beauty of the fls. Some of the species are reported to possess medicinal properties. These plants have been referred to *Cereus*.

A. *Fl.-tube and ovary without long hairs.*

B. *Spines on sts. acicular.*

vågans, Brit. & Rose (*Cereus vågans*, Brandeg.). Sts. slender, numerous, clambering over rocks in the wild state, but in cult. ascending: ribs low: spines rather short, yellowish: fls. 6 in. long; tube, including throat, about 4 in. long, slightly curved, brownish, with small scattered bracts bearing in their axils clusters of 5–8 acicular spines; throat narrow, 2 in. long; sepals linear, the outer ones brownish, the inner ones greenish white, $2\frac{1}{2}$ in. long; petals white, oblanceolate, $2\frac{1}{2}$ in. long with a short acuminate tip, the margins, especially above, undulate or toothed; ovary covered with acicular spines. West coast of Mex.

BB. *Spines on sts. not acicular.*

spinulosus, Brit. & Rose (*Cereus spinulosus*, DC.). Slender climbing vine, 10–14 ft. long: ribs usually 5, not very conspicuous in age: spines about 8, very short, usually dark: fls. $4\frac{1}{2}$ –5 in. long, white, with a pink tinge; ovary and fl.-tube bearing small clusters of acicular spines but no long hairs. Common in N. E. Mex. and S. E. Texas, but not found in the W. Indies. Blühenden Kakteen, pl. 53.

AA. *Fl.-tube and ovary bearing long hairs among the spines.*

B. *Spines of the sts. acicular.*

c. *Color of spines white.*

Donkelæri, Brit. & Rose (*Cereus Donkelæri*, Salm-Dyck). A slender epiphytic plant, much branched, clinging to the bark of trees by aerial roots, commonly in company with orchids: branches long, slender, nearly terete, about $\frac{3}{8}$ in. diam. with 6–8 low, almost inconspicuous ribs; spines 10–15, very short, snow-white, closely appressed to the st. Brazil.

cc. *Color of spines brownish.*

grandiflorus, Brit. & Rose (*Cereus grandiflorus*, Mill.). Creeping or clambering vines: sts. stout, often 1 in. diam., bluish green: ribs 7 or 8, low: spines acicular, yellowish brown or brownish: fls. very large, fragrant, 6–8 in. long. Jamaica, but said also to be native of Mex., which is doubtless wrong. B.M. 3381.—A number of species resembling *S. grandiflorus* in a general way, but specifically distinct, are often to be found under this name in collections; they need further study. This species is used in the manufacture of a heart- tonic.

BB. *Spines of the sts. not acicular.*

c. *Sts. blue-green.*

pteránthus, Brit. & Rose (*Cereus pteránthus*, Link & Otto. *Cereus nyctiodlus*, Link). Stout, suberect, or clambering vines; branches much elongated, bluish green, 4- or 6-angled; spines 1-4, short; fls. large, white, very fragrant, 7 in. long, the ovary covered with long white hairs intermixed with the short acicular spines. Mex. Lem. Cact. f. 11. Gesamtb. Kakteen f. 35.—One of the commonest and best night-blooming cacti.

cc. *Sts. deep green.*

d. *Knobs on ribs terete and low.*

MacDónaldia, Brit. & Rose (*Cereus MacDónaldia*, Hook.). Clambering vines of rapid growth, freely branching; branches deep green; the ribs rather low, obtuse, somewhat interrupted; spines 1 or 2, short, porrect, dark; fls. very large, 14 in. long, white. Honduras, probably, but some recent writers claim it came originally from Argentina. B.M. 4707. Cact. Journ. 2:135.—One of the largest-flowered species of the cactus family and one of the best of the night-blooming kind.

dd. *Knobs on ribs flattened, rather high and reflexed.*

hamátus, Brit. & Rose (*Cereus hamátus*, Scheidw. *C. rostrátus*, Lem.). Sts. often weak and sprawling or climbing and clambering, bright green, about 8 in. diam.; ribs usually 4, interrupted by flattened reflexed knobs bearing small areoles; spines 5 or 6, bristle-like, white; hairs more or less deciduous; fls. large, 10-12 in. long, white. Cent. Mex. Monatsschr. Kakteenk. 9:23. Gesamtb. Kakteen Nachtr. f. 7.—Numerous hybrids have been made by crossing some of these species, especially *S. grandiflorus*, *S. MacDónaldia*, and *S. hamátus*, with certain species of related genera. Some of these hybrids have been given distinct names in *Cereus*, such as *C. Maynardii*, *C. Regelii* and *C. urános*.

Cereus inermis, Otto. Sts. slender, climbing, 4-5-angled, deep green; areoles small, naked except on juvenile shoots and then bearing several white bristles; fls. said to be large, probably nocturnal, but not often appearing on cult. plants. This is a rather insignificant plant. Intro. from Venezuela many years ago. This is not a true *Cereus*, and without seeing fls. or fr. its real status can not be definitely stated. Karl Schumann, however, associated it with this group, and if of this alliance, it should be placed near *S. hamátus*.

J. N. ROSE.

SELENIPEDIUM. For the species included in this genus in "Cyclopedia of American Horticulture," see *Phragmopedium*. The true *Selenipedium* (or *Selenipedium*) are few and seem not to be in cult.

SELENOCYPRIPEDIUM (compounded from *Selenipedium* and *Cypripedium*). *Orchidaceae*. A name proposed to designate hybrids between *Selenipedium* and *Cypripedium*. *S. Malhoitri*=*S.* (*Phragmopedium*) *Schlimii* × *C.* (*Paphiopedilum*) *Harrisianum*.

SELF-HEAL: *Brunella*.

SELF-STERILITY OF FRUITS: *Pollen and Pollination*.

SELINUM (Greek name for parsley). *Umbelliferae*. Branched perennial herbs, glabrous, tall or rarely low, of little horticultural value; lvs. pinnately decomposed; umbels compound, many-rayed; fls. white or rarely yellowish green; calyx-teeth obsolete or rarely noticeable; petals cuneate or broad, emarginate or 2-lobed; fr. ovoid or nearly quadrate.—About 35 species, mostly in the northern hemisphere but 1 from the mountains of Colombia and 1 from S. Afr.

tenuifolium, Wall (*Oreócome Candollei*, Edgew.). A hardy perennial with finely cut fern-like foliage and st. often 8 ft. high, branched, with numerous umbels of white fls.; ultimate segms. of lvs. narrowly lanceolate, acute; fr. 2-3 lines long, much compressed dorsally, 4-6 times as broad as thick; lateral ridges much the broadest. India. Gn. 38, p. 221.—Offered as a novelty in Amer. in 1899 and recommended as a foliage plant for single lawn specimens.

F. TRACY HUBBARD.†

SELLIÈRA (named for Natale Sellier, a French engraver who worked for Cavanilles). *Goodeniaceae*. Two creeping and rooting perennial herbs of Austral. and New Zeal. and one of them extending to Chile: plant glabrous; lvs. entire, alternate or fascicled; fls. small, axillary, sessile or stalked; calyx 5-lobed; corolla oblique, split at the back, 5-lobed; stamens 5; ovary 2-celled or imperfectly so; fr. fleshy and indehiscent. The plants are probably not regularly in cult.; but *S. radicans*, Cav., has been listed abroad as an aquatic: it grows in muddy or marshy and rocky places near the sea in New Zeal., Austral., and S. Amer.: sts. sometimes creeping several feet, forming matted and interlaced patches; lvs. very small to 4 in. long, nearly linear to obovate-spatulate, obtuse, entire, narrowed into long petiole; fls. 1 or 2 on the peduncle, ½ in. long, white; fr. about ¼ in. long, ovoid or obovoid. See Krause, in Engler's *Pflanzenreich*, hft. 54 (IV. 277 & 277a). 1912.

SELLIGUÈA (personal name, from Selligue, naturalist and mechanician). *Polypodiaceae*. A group of ferns referred by Diels (Engler & Prantl, *Die Natürlichen Pflanzenfamilien*) to *Polypodium*. Only *P. Féei*, Mett. (*Selliguèa Féei*, Bory. *Gymnogramma Féei*, Hook.), appears to be listed. It is described by Schneider as a small stove species of the Malay Isls., Java, and Borneo: fronds entire, from a creeping rhizome, the barren ones 3-4 in. long and 2 in. or less broad, the fertile ones narrower and longer-stalked.

SEMECÁRPUS (Greek, *mark and fruit*, referring to use of fruit-juice). *Anacardiaceae*. Trees, sometimes grown in the warmhouse, or in the open far S.: lvs. alternate, simple, leathery; fls. small, polygamous, in terminal or lateral, branched, bracteate panicles; calyx 5-cleft, segms. imbricated and deciduous; petals 5, spreading, somewhat unequal; disk annular and rather broad; stamens 5; ovary superior, sessile, 1-celled; nut or drupe reniform.—About 35 species, Trop. Asia and Austral.

Anacárdium, Linn. f. MARKING-NUT TREE. A moderate-sized deciduous tree with large, oblong or obovate-oblong lvs. 8-24 in. long by 5-10 in. wide; fls. greenish white, ¼ in. across, nearly sessile, in stout branching panicles about the same length as the lvs.; drupe 1 in. long, smooth, black. India.—The black acid juice of the nut is used for printing cotton cloth. Cult. in S. Fla.

SÉMELE (named for the mother of Bacchus). *Liliaceae*. CLIMBING BUTCHER'S BROOM. A warmhouse plant, hardy outdoors in the extreme S.: st. shrubby and branched, high-climbing over trees attaining a height of 50-60 ft., cladodia lf.-like, alternate or few, solitary at the axils of fuscous-membranaceous scales, ovate-lanceolate, acuminate, leathery; fls. small, yellow, fascicled, the fascicles on the margins of the cladodia; perianth persistent, tube very short, turbinate, almost hemispherical; crown none; ovary sessile in the perianth-tube, 3-celled; berry globose, pulpy, indehiscent.—One species, Canary Isls. What appear to be lvs. are technically "cladophylla," i. e., lf.-like branches. They are organs which have the form and function of lvs. but not the morphology. *Semele* belongs to the small group of 4 genera known as the *Asparagus* tribe, all the members of which have cladophylla. *Semele* differs from the butcher's broom (*Ruscus*) in having 6 anthers instead of 3 and in having the fls. borne on the margin of the cladophylla instead of along the midrib. *Asparagus* differs from both in having the fls. not borne on the cladophylla and the filaments free instead of grown into an urn-shaped body.

andrógyna, Kunth (*Ruscus andrógynus*, Linn.). Scandent, branching; cladodia ovate or ovate-lanceolate, acuminate, leathery; fls. small, yellow, clustered; ovary 3-loculed; berry globose, indehiscent. B.M. 1898 and 3029 (as *Ruscus androgynus*). R.H. 1894, p. 546.

Gn. 72, p. 432. G.M. 31:477, 479; 37:261.—The members which have the position of lvs. are minute scales, in the axil of which are borne the cladophylla, the latter being 3-4 in. long. It is grown in the open in S. Calif. and is said to look like a gigantic smilax and to have dark green tropical foliage likely to be mistaken for some of the Indian climbing palms.

F. TRACY HUBBARD.†

SEMIBEGONIÉLLA is a recent genus of the Begoniaceæ, differing from *Begonia* in having a tubular male flower (Symbegonia has a tubular female flower), apparently not in cult. *S. Sodiroi*, C. DC., from Ecuador was described, and the genus founded, in 1908.

SEMPERVIVUM (Latin, *living forever*). *Crassulaceæ*. HOUSELEEK. Thick fleshy usually stemless, perennial herbs or subshrubs which are used for carpet-bedding, rockeries, and the like. See *Succulents* (p. 2672, Vol. V) for culture.

Leaves alternate, thick-fleshy, often revolute: cymes paniced, usually densely: fls. white, rose, green, yellow, or purple; calyx 6- to many-cleft or -parted, rarely 5-cleft; petals 6 to many, free or connate at the base, oblong or lanceolate; stamens double as many as the petals, rarely the same number, free; ovary with as many carpels as petals, free or the base or up to the middle immersed in the calyx-tube: fr. many-seeded follicles.—About 65 species, widely scattered in the mountains of the Old World. The genus was monographed (horticulturally) by J. G. Baker in *Gardener's Chronicle* for 1879, and his treatment has been followed here to some extent with the addition of several species and slight modifications to meet more recent knowledge of the genus. *Sempervivum* is closely related to *Sedum*, but the floral parts are multiples of 6 or some larger number, while the floral parts of *Sedum* are in 5's. The genus is a difficult one for the botanist, and the specific limits are very uncertain and unsatisfactory, no two authors agreeing. The key given will undoubtedly prove faulty, but is an attempt to simplify the determination of the species.

Sempervivums are mostly hardy perennials and stemless, and increase by rosettes (Fig. 3602) which are sent out from the parent plant, thereby suggesting the popular name "hen-and-chickens." The leaves are thick, short, and succulent. The flowers, which are borne in paniced cymes, are mostly yellow, greenish yellow, or some shade of rose or purple, rarely white. The individual flowers are larger than those of *Sedum*, but the clusters are less showy. Houseleeks are cultivated more for foliage than for flowers. They are not used for as great a variety of purposes as sedums, but they are popular for carpet-bedding, rockwork, and covering dry banks and bare sandy wastes. They are of the easiest culture and are quickly multiplied by means of the offsets or rosettes. They may be used alone for permanent carpet-beds, and for this special purpose are preferable to the more popular but tender *echeveria*. The foliage remains green all winter. The leaves are often spotted with red toward the tip, and this color is brighter if the plants have full sunlight. The names "houseleek" and "hen-and-chickens" are loosely applied to the whole genus. If these names are to be restricted, the former should be used for *Sempervivum tectorum* and the latter for *S. soboliferum*. The common species, which grows on the roofs of houses in Europe, is *S. tectorum*. In the case of *S. soboliferum* the young rosettes are attached to the parent plant by a more slender thread than usual and more easily detach themselves and roll about. The spider-web species, of which *S. arachnoideum* is the commonest, are the prettiest of them all, by reason of the webs that cover the young rosettes. These coverings are made by the plants themselves and are incidental to development, but in some species are not strongly developed and in all the group are less noticeable in the old rosettes.

KEY TO THE SPECIES.

- A. Plants without secondary rosettes on offshoots: fls. usually yellow.
 - B. St. herbaceous, with the basal lvs. in a rosette. 1. *poculiforme*
 - BB. St. shrubby, with the lvs. in a rosette at the end of the branches.
 - C. Surface of lvs. villous. 2. *canariense*
 - CC. Surface of lvs. glabrous.
 - D. Lvs. obovate-spatulate or roundish ovate.
 - E. Petals elliptical; calyx-segms. ovate. 3. *arboresum*
 - EE. Petals linear-lanceolate; calyx-segms. short-triangular. 4. *chrysanthum*
 - DD. Lvs. oblong-spatulate.
 - E. Margin of lvs. ciliate. 5. *tabuleforme*
 - EE. Margin of lvs. papillose. 6. *spathulatum*
 - AA. Plants with secondary rosettes on offsets or sessile.
 - B. Fls. usually 6-merous; not wide-spreading at maturity.
 - C. The fls. small; petals not fimbriated on the margin and keel.
 - D. Segms. of calyx linear-oblong; petals linear-oblong. 7. *Heuffelii*
 - DD. Segms. of calyx lanceolate; petals lingulate. 8. *Reginæ-Amaliæ*
 - CC. The fls. large; petals fimbriated on the margin and keel.
 - D. New rosettes rolled up into round balls.
 - E. Lvs. obovate-cuneate. 9. *soboliferum*
 - EE. Lvs. oblanceolate. 10. *arenarium*
 - DD. New rosettes not rolled up into round balls. 11. *hirtum*
 - BB. Fls. usually 12-merous (9-14-merous); widely expanded at maturity.
 - C. Color of fls. yellow or yellowish.
 - D. Surface of lvs. glabrous.
 - E. The lvs. obovate-cuneate. 12. *Wulfenii*
 - EE. The lvs. ovate-lanceolate. 13. *albidum*
 - DD. Surface of lvs. more or less hairy.
 - E. Blade of lf. ensiform, lingulate, or oblanceolate. 14. *Pittonii*
 - EE. Blade of lf. more or less obovate-cuneate.
 - F. Segms. of calyx oblong. 15. *rupicolum*
 - FF. Segms. of calyx lanceolate.
 - G. Petals linear-lanceolate, acute, green-striate externally. 16. *globiferum*
 - GG. Petals lanceolate, acuminate, not green-striate externally. 17. *grandiflorum*
 - CC. Color of fls. reddish or purplish.
 - D. Inner lvs. of rosette with their tips connected by fine hairs like a spider's web. (The following 5 species are very closely related.)

- E. Rosette lvs. glabrous or merely puberulent at apex.
 F. Calyx-segms. lanceolate-linear, acute; cauline lvs. lanceolate-linear.....18. hetero-[trichum
 FF. Calyx-segms. linear, obtuse; cauline lvs. oblanceolate to oblong.....19. Moggridgei
 EE. Rosette lvs. more or less hairy.
 F. Segms. of calyx linear.....20. arachnoideum
 FF. Segms. of calyx ovate to lanceolate.
 G. Cauline lvs. lanceolate; rosette lvs. oblanceolate.21. Doellianum
 GG. Cauline and rosette lvs. lingulate.....22. Laggeri
 DD. Inner lvs. of rosettes not connected by fine hairs like a spider's web.
 E. Tips of lvs. with a tuft of hairs.
 F. Lvs. ovate.....23. Hausmannii
 FF. Lvs. oblanceolate.
 G. Cusp of lf. distinct; fls. rose-red.....24. Pomelii
 GG. Cusp of lf. obscure; fls. bright red.....25. fimbriatum
 EE. Tips of lvs. without a tuft of hairs.
 F. Surface of lvs. of the rosettes pubescent.
 G. Stamens two-thirds as long as petals.....26. assimile
 GG. Stamens half as long as petals.
 H. Barren rosettes not more than 1 in. diam.....27. pumilum
 HH. Barren rosettes more than 1 in. diam.
 I. Fls. numerous, mauve or red-brown.....28. montanum
 II. Fls. few (4-8), bright red.....29. flagelliforme
 FF. Surface of lvs. of the rosettes glabrous.
 G. Rosette lvs. more or less ovate or obovate.
 H. Lf.-blade broadest toward the base.
 I. Color of lvs. dark green.....30. Schnitt-[spahnii
 II. Color of lvs. gray-green.....31. Mettenianum
 HH. Lf.-blade broadest toward the apex.
 I. Petals lanceolate...32. blandum
 II. Petals linear.
 J. Sepals linear-lanceolate.....33. Lamottei
 JJ. Sepals lanceolate.34. tectorum
 GG. Rosette lvs. oblanceolate-cuneate.
 H. Red-brown tip of rosette lvs. none or obscure.
 I. Young rosettes on peduncles 1 in. or more long.....35. Funckii
 II. Young rosettes sessile or nearly so.
 J. Lvs. glaucous...36. glaucum
 JJ. Lvs. pale green but not glaucous.
 K. Cauline lvs. green-tipped; petals rose...37. Verlotii
 KK. Cauline lvs. claret-tipped; petals white-margined...38. atlanticum
 HH. Red-brown tip of rosette lvs. distinct.
 I. The cauline lvs. red-brown throughout.39. triste
 II. The cauline lvs. partly green.

- J. Rosette lvs. glaucous.
 K. Outer lvs. of rosette $\frac{3}{4}$ -1 x $\frac{1}{2}$ in.; fls. about $\frac{1}{2}$ in. across..40. Greenii
 KK. Outer lvs. of rosette 1-1 $\frac{1}{4}$ x $\frac{3}{8}$ in.; fls. about $\frac{3}{4}$ in. across.....41. calcareum
 JJ. Rosette lvs. not glaucous. (The following species are frequently kept distinct but no distinguishing key characters can be detected from the descriptions.)
 42. arvernense
 43. Boutigny-anum
 44. alpinum
 45. Boissieri

1. *poculifórm*e, Berger & DeWild. St. simple, erect, more or less elongated; basal lvs. in a rosette, oblong-lanceolate, cuneate at the apex, serrate-ciliate, otherwise glabrous; cauline lvs. obovate-spatulate; fls. 9-merous, in a glabrous panicle; calyx glabrous, segms. lanceolate-triangular subacute; petals lanceolate, acute. Canary Isls.(?).

2. *canariense*, Linn. Subshrub: st. short, thick; lvs. in a flattened rosette, obovate-spatulate, mucronate, attenuate to a petiole, villous; cauline lvs. obovate-rotundate; fls. 7-9-merous, pale yellow or whitish, in a lax thyrsoid elongated panicle; calyx very villous, segms. ovate-lanceolate; petals linear, acute. Canary Isls.

3. *arbóreum*, Linn. St. arborescent, with terete branches: rosettes concave; lvs. spreading, obovate-spatulate, obtuse, mucronate, base cuneate, rather glabrous; fls. golden yellow in a many-fld. leafy panicle; calyx-segms. ovate, rather acute; petals spreading, 10-12, elliptical. Medit. region.

4. *chrysánthum*, Hochst. Subshrub, 1-2 ft. high: st. thick; lvs. pectinate-ciliate, on barren shoots rosulate, roundish ovate; cauline lvs. obovate-oblong, rounded above, apiculate; fls. about 8-merous, yellow, or white(?), in a thyrsoid corymb; calyx-segms. short-triangular; petals linear-lanceolate. Abyssinia.—Closely allied to *S. arboreum* and possibly not distinct from it.

5. *tabulæfórm*e, Haw. Shrubby: sts. erect-branched: lvs. oblong-spatulate, base attenuate, flat, ciliate, gathered at the tips of the branches in a flat rosette; peduncles minutely glandular; petals linear-lanceolate, very pale sulfur. Canary Isls.

6. *spathulátum*, Hornem. (*S. barbátum*, C. Smith. *Æonium barbátum*, Webb & Berth.). Shrubby: sts. stout; branches horizontal near the st., then arched and erect; rosettes flat, not dense: lvs. of the rosettes oblong-spatulate, acute, margin papillose, both surfaces with linear, red-brown markings; cauline lvs. linear-lanceolate, acuminate; fls. 8-10-merous, in rather open panicles, the fls. on the upper side of the branches; calyx-segms. deltoid; petals oblong-lanceolate, acute. Canary Isls.—Some of the material grown under this name is certainly not the species above described, but probably a form of *S. tectorum*.

7. *Heußfelii*, Schott (*S. párens*, Griseb. & Schenk). Barren rosette 1 $\frac{1}{2}$ -2 in. diam., the young rosettes not peduncled: lvs. 30-40 to a rosette, obovate-cuneate, distinctly cuspidate, glabrous, lower part pale green, upper third or even half tinted bright red-brown, margin crowded, stiff, white-ciliate, outer lvs. $\frac{3}{4}$ -1 x $\frac{3}{8}$ in.;

cauline lvs. close, red-brown, lanceolate, $\frac{3}{4}$ –1 in. long; fl.-st. including the infl. 6–8 in. high, densely short-pubescent; fls. 6-merous, pale straw-color, in a dense panicle $2\frac{1}{2}$ –3 in. diam.; calyx-teeth linear-oblong, finely glandular-pubescent on the back and red-brown when old; petals $\frac{3}{8}$ in. long, linear-oblong, obtuse, with 3 small cusps, keeled and finely glandular outside. Transylvania and Greece in the mountains.—One of the latest in flower.

8. *Reginæ-Amaliæ*, Heldr. & Sart. Rosettes about 3 in. diam., the new ones sessile; lvs. 100 or more to a rosette, obovate-cuneate, distinctly cuspidate, all bright purplish brown in the upper half, green only toward the base, glabrous, margin ciliate, outer lvs. $1\frac{1}{4} \times \frac{1}{2}$ – $\frac{5}{8}$ in.; cauline lvs. crowded, lanceolate, brown, slightly pubescent; fl.-st. including infl. 6 in. high, densely pubescent; fls. 6–7-merous, pale yellow, in a dense many-fld., capitate panicle; calyx finely glandular-pubescent, segms. lanceolate; petals lingulate, obtuse, obscurely tricuspidate, densely glandular externally. Mountains of Greece.

9. *soboliferum*, Sims (*S. globiferum*, Linn. as to synonyms and many other authors, not Linn. as to plant cited). HEN-AND-CHICKENS. HOUSELEEK. Barren rosettes globose, $1\frac{1}{2}$ in. diam., the copious new rosettes sessile and attached to the parent only by a slender thread and easily becoming detached from it and rolling about; lvs. 60–80 to a rosette, obovate-cuneate, obscurely cuspidate, pale light green, glabrous, margin minutely ciliate, outer ones tinted with red-brown especially on their back, $\frac{3}{4}$ –1 $\times \frac{1}{4}$ – $\frac{3}{8}$ in.; cauline lvs. very densely crowded, ovate-lanceolate, acute; fl.-st. including infl. 6–9 in. high, very robust, finely pubescent; fls. 6–7-merous, pale yellow, in a short, dense, many-fld. panicle, which is 3–4 in. diam.; calyx-segms. lanceolate, nearly glabrous on the back, margins strongly ciliate; petals lanceolate, $\frac{1}{2}$ in. long, obscurely tricuspidate, margins conspicuously fimbriate. Mountains of Austria. B.M. 1457.—Unless the young rosettes are thinned out the plants are not so apt to flower.

10. *arenarium*, Koch. (*S. Neireichii*, Schott, Nym. & Kotschy). Rosettes globular, deciduous; lvs. 60–80 to a rosette, oblanceolate, acute, bright green, glabrous, outer lvs. slightly tinted red-brown on the back, $\frac{1}{2}$ – $\frac{3}{4}$ in. long; cauline lvs. ovate-lanceolate; fls.-sts. including the infl. 6–9 in. high, crowded, leafy and finely pubescent; fls. 6-merous, pale yellow, many in a dense head, 2–3 in. diam.; sepals lanceolate; petals lanceolate, $\frac{1}{2}$ – $\frac{5}{8}$ in. long, distinctly tricuspidate with a linear end tooth. Tyrol. Gn. 49, p. 220.

11. *hirtum*, Linn. (*S. Allidonii*, Nym. *S. cornutum*, Hort.). Developed barren rosettes $1\frac{1}{4}$ in. diam., the new ones not rolled up into balls and breaking away as in *S. soboliferum*: lvs. about 50 to a rosette, obovate-cuneate, not distinctly cuspidate, pale gray-green, surfaces finely glandular-pubescent, margins glandular-ciliate, outer lvs. faintly tinted red, $\frac{1}{2}$ – $\frac{3}{4} \times \frac{1}{8}$ in.; cauline lvs. crowded, pubescent, the upper cordate-ovate; fl.-st. including infl. 6–9 in. high, densely pilose; fls. usually 6-merous, pale yellow, in a few- to many-fld. panicle which is $\frac{1}{2}$ –4 in. diam.; calyx-segms. lanceolate, hairy on their back; petals $\frac{1}{2}$ – $\frac{3}{4}$ in. long, lanceolate, tricuspidate, the middle tooth conspicuous, keel prominent, tinted greenish red and is densely glandular. S. Eu.

12. *Wulfenii*, Hoppe. Developed rosettes $1\frac{1}{2}$ –2 in. diam., the new ones nearly sessile; lvs. about 50 to a rosette, obovate-cuneate, cuspidate, slightly glaucous, with only a faint tint of red-brown at the very tip, outer lvs. $\frac{3}{4}$ –1 $\times \frac{3}{8}$ in.; cauline lvs. lanceolate, $1\frac{1}{2}$ in. long; fl.-st. including infl. 6–9 in. high, densely pilose upward; fls. 12–14-merous, pale yellow, in a short dense panicle which is 2–3 in. diam., its branches densely pilose; calyx short-pilose, segms. lanceolate; petals linear, densely glandular-puberulent externally. Mountains of Cent. Eu.

13. *albium*, Schnittsp. & Lehm. Rosettes large, the young ones 1–3 in. away from the old one: lvs. of rosettes ovate-lanceolate, narrowed at their base, apex rather long-acuminate, glabrous, finely ciliate, dark grass-green, tips reddish brown; cauline lvs. equally broad, long-acuminate; fls. whitish, racemose paniculate; petals linear-lanceolate. Hab.(?).

14. *Pittonii*, Schott., Nym. & Kotschy. Rosettes $1\frac{1}{2}$ in. diam., always open, the young ones sessile; lvs. 60–80 to a rosette, ensiform, lingulate or oblanceolate, apex abruptly deltoid-pointed, pale green with large light red blotches, outer lvs. $\frac{3}{4}$ in. long; cauline lvs. dense, lanceolate, red-blotched and purple-tipped, densely glandular-hairy; fl.-st. including infl. 4–6 in. high, glandular-hairy ending in a 3-branched, dense corymbose infl.: fls. 12–20, small, 9–12-merous, yellowish white; petals linear-lanceolate, about $\frac{3}{8}$ in. long, glandular-hairy on the margin and back. Styria.—Rare in cult.

15. *rupicolum*, Kern. Rosettes $1\frac{1}{2}$ –2 in. diam., the young ones on glandular-hairy peduncles which are $1\frac{1}{2}$ –2 $\frac{1}{2}$ in. long; lvs. elongated-obovate, $\frac{1}{2}$ – $1\frac{1}{4} \times \frac{1}{4}$ – $\frac{3}{8}$ in., narrowed gradually from the upper one-third to the reddish base, cuspidate, slightly scattered glandular-hairy; cauline lvs. ovate-lanceolate, $\frac{3}{8}$ – $\frac{3}{4}$ in. long, tip reddish; fl.-st. slender, glandular-hairy; fls. 12-merous, pale greenish yellow, striped red; calyx-segms. oblong; petals narrowly linear-lanceolate, acute. Tyrol.—Probably a hybrid; *S. montanum* $\times$ *S. Wulfenii*.

16. *globiferum*, Linn. in part, excl. synonymy (*S. ruthenicum*, Koch). Rosette $1\frac{1}{2}$ –3 in. across, rather flattened, the young ones globular, borne on scaled peduncles which are rather stout and about $1\frac{1}{2}$ –3 in. long; lvs. obovate-cuneate to elliptical, gray-green, cuspidate; cauline lvs. oblong, acute, about $1\frac{1}{4} \times \frac{1}{2}$ in., tip often red-brown; fl.-st. about 1 ft. high, including infl., densely short-hairy; fls. pale yellow, 12–14-merous, about $\frac{3}{4}$ –1 in. across; calyx-segms. lanceolate, acute; petals linear-lanceolate, acute, externally glandular-hairy and green-striate, margins glandular-ciliate. Russia in Eu.—As Koch points out in Flora 18, part 1:209, t. 1 (1835), the synonymy given by Linnaeus undoubtedly refers to *S. soboliferum*, a 6-merous species, but that the one plant Linnaeus cites and his "habitat in Rutheno. D. Gmelin" undoubtedly refer to the 12-merous plant which Besser knew under the name *S. globiferum* and which he, Besser, sent to Koch in 1834.

17. *grandiflorum*, Haw. (*S. globiferum*, Sims, not Linn.). Rosettes about $1\frac{1}{2}$ in. diam., the new ones on decumbent peduncles 1–2 in. long, which have small lvs.: lvs. about 40 to a rosette, obovate-cuneate, obscurely cuspidate, pale green, pubescent, only the tip obscurely red-brown tinted, outer lvs. $\frac{3}{4}$ –1 $\times \frac{1}{4}$ – $\frac{1}{2}$ in.; cauline lvs. crowded, lanceolate, $\frac{3}{4}$ –1 in. long; fls.-sts. including infl. 3–8 in. high, densely pubescent; fls. 12–14-merous, $1\frac{1}{4}$ – $1\frac{1}{2}$ in. across, pale yellow, subsessile in a dense paniculate head; calyx pubescent, segms. lanceolate; petals lanceolate, acuminate, back glandular. Hab.(?). B.M. 507; 2115(?).

18. *heterotrichum*, Schott. Rosettes $1\frac{1}{2}$ in. diam.: fl.-sts. 3–6 in. high, puberulent pubescent; lvs. of the rosette spatulate-linear, apex acute, with a tuft of hairs and also long web-hairs connecting the lf.-tips, puberulent at the apex above, glabrous beneath, glaucous; cauline lvs. lanceolate-linear, puberulent on both sides; infl. puberulent; fls. 9–12-merous, rose, in a racemose panicle; calyx-segms. lanceolate-linear, acute; petals lanceolate, acuminate, ciliate, apex barbate. S. Eu.—Closely allied to *S. Doellmanum* and *S. arachnoideum*.

19. *Moggridgei*, De Smet. Rosettes 2 in. diam.: lvs. about 100 to a rosette, $\frac{3}{4}$ in. long, elongate-cuneate or oblanceolate, green, glabrous, margins minutely ciliate,

tips acute and hairy tufted; cauline lvs., the lower oblanceolate, $\frac{3}{4}$ in. long, tips bearded, pale green, tips reddish, the upper more oblong; cyme 3-4 times forked: fls. 10-12-merous, $\frac{3}{4}$ in. diam.; calyx glandular-pubescent, segms. linear, obtuse; petals lanceolate, acuminate, apiculate. S. Eu. B.M. 6610.—Allied to *S. arachnoideum*.

20. *arachnoideum*, Linn. (*S. Haussmannii*, Auersd., not Lehm. & Schnittsp. *S. piliferum*, Jord.). COBWEB or SPIDER-WEB HOUSELEEK. Fig. 3601. Barren rosettes

3601. *Sempervivum arachnoideum*.
($\times \frac{1}{2}$)

$\frac{1}{2}$ – $\frac{3}{4}$ in. diam., the new ones crowded and sessile: lvs. about 50 to a rosette, oblong-cuneate, obscurely cuspidate, pale green, tips of nearly all the lvs. connected with long soft white hairs, outer lvs. tinted with red-brown on the back, about $\frac{3}{4}$ in. long; cauline lvs. oblong-lanceolate, small, tips with a dense tuft of hairs: fl.-sts. 3-4 in. high including the dense few-fl. panicle: fls. 9-12-merous, about 1 in. across; calyx-segms. linear; petals lanceolate, bright red. S. Eu. B.M. 68. G.L. 26:201. Gn. 78, p. 437. Var. *tomentosum*, Cariot (*S. tomentosum*,

Schnittsp. & Lehm. *S. Webbii*um, Hort.), has white tomentose rosettes, with more obovate-cuneate lvs. and the rosettes are flatter and more compact. Var. *Hookeri*, Hort., is offered in the trade. Var. *minor*, Hort., is offered in the trade. Var. *rubrum*, Hort., is offered in the trade.

21. *Doellianum*, C. B. Lehm. Barren rosettes $\frac{1}{2}$ – $\frac{3}{4}$ in. diam., the new ones shortly peduncled: lvs. 40-50 to a rosette, oblanceolate, obscurely cuspidate, pale green, surface slightly hairy, the tips of only the inner ones connected by a few arachnoid threads, the outer $\frac{1}{4}$ – $\frac{3}{4}$ in. long, tinted with red on the back; cauline lvs. lanceolate, $\frac{1}{2}$ – $\frac{3}{4}$ in. long, with only an obscure tuft of short hairs at the tips: fl.-st. including infl. 4-6 in. high: fls. 9-10-merous, bright red, in a compact, few-fl. panicle; calyx densely pubescent, segms. lanceolate; petals lanceolate, $\frac{1}{2}$ in. long. Switzerland and Tyrol.—Closely allied to *S. arachnoideum*, by some authorities considered a variant of it.

22. *Lägeri*, Schott (*S. arachnoideum* var. *Lägeri*, Rouy. & Fouc.). Rosettes up to $\frac{1}{2}$ in. diam., open, the young ones close to the old ones or on peduncles up to $\frac{1}{4}$ in. long: lvs. gray-green, red-violet at the tip, short glandular-hairy, at least above, lingulate, about $\frac{1}{2}$ in. long, apex blunt, suddenly apiculate; cauline lvs. $\frac{5}{8}$ – $\frac{1}{2}$ in. long, rather dense, hairy, tip tufted hairy and red- or black-violet and red- or black-violet-dotted: fls. bright rose, in a rather dense panicle borne on a reddish st.; calyx-segms. ovate-elongated, acute; petals oval-lanceolate with the midnerve darker. Switzerland. Gn. 78, p. 470.—Closely allied to *S. arachnoideum* and considered a variety of it by some authorities. There is a strong-growing variant of this species offered in the trade under the name *S. arachnoideum* var. *Lägeri gigantea*, Hort.

23. *Haussmannii*, Lehm. & Schnittsp. Rosette medium-sized, somewhat flat: lvs. of the rosette ovate, cuspidate, glabrous, margins ciliate, tip ciliate-tufted, green, brownish at the tip: fl.-st. 5-6 in. high, erect: fls. 12-14-merous, rose-red in a dense many-fl. panicle; calyx-segms. ovate-lanceolate, acute, glandular-ciliate; petals ovate to linear-lanceolate, lower surface keeled, margin glandular-ciliate. Tyrol.

24. *Pömelii*, Lamotte; also misspelled *Poemlii*. Barren rosette $1\frac{1}{2}$ – $1\frac{3}{4}$ in. diam., the new ones nearly sessile: lvs. 50-60 to a rosette, oblanceolate, with a distinct cusp, a few hairs on both surfaces, the cusp furnished with an inflexed tuft of hairs, outer lvs. $\frac{3}{4}$ – $1 \times \frac{1}{4}$ in., tinged with red; cauline lvs. much imbricated, lanceolate, hairy, the lower $1-1\frac{1}{2}$ in. long: fl.-st. including infl. 6-9 in. high, densely pilose: fls. 10-12-merous, about 1 in. across, rose-red, in a panicle 3-4 in. diam., its simple branches 6-12-fl.; calyx densely pilose, segms. linear-lanceolate, glandular; petals linear-lanceolate. France.

25. *fimbriatum*, Schnittsp. & Lehm. Barren rosette $1-1\frac{1}{2}$ in. diam., the new rosettes nearly sessile: lvs. 50-60 to a rosette, oblanceolate, obscurely cuspidate, green, margins deflexed hairy, tip with a tuft of hairs, outer lvs. becoming red, $\frac{1}{2}$ – $\frac{3}{4}$ in. long; cauline lvs. pilose, lanceolate, red-tinted, much imbricated, lower ones $1-1\frac{1}{2}$ in. long: fl.-sts. including infl. 6-10 in. high, densely glandular-pilose: fls. about 12-merous, 1 in. across, bright red, in an open few-branched panicle; calyx glandular-pilose, segms. linear-lanceolate; petals lanceolate. Pyrenees and Tyrol. Gn. 78, p. 47.

26. *assimile*, Schott. Rosettes of barren lvs. $1\frac{1}{2}$ –2 in. diam., the new ones nearly sessile: lvs. 60-80 to a rosette, obovate-cuneate, cuspidate, pale glaucous green, not red-tipped, margin short-ciliate, surface minutely pubescent, outer lvs. $\frac{3}{4}$ –1 in. long: fl.-sts. including the infl. about 6 in. high: fls. 12-merous, about $\frac{3}{4}$ in. across, pale rose; calyx-segms. lanceolate; petals linear. Transylvania.

27. *pumilum*, Bieb. (*S. anomalum*, Hort.). Barren rosette at most 1 in. diam., the copious new rosettes shortly peduncled: lvs. 30-40 to a rosette, oblanceolate, cuspidate, green, pubescent, end mucro obscure, outer lvs. only tinted red-brown, $\frac{5}{8}$ – $\frac{1}{2} \times \frac{1}{4}$ in.; cauline lvs. lanceolate, hairy all over, tinted red-brown, the lowest $\frac{1}{2}$ – $\frac{3}{4}$ in. long: fl.-st. including infl. not more than 3-4 in. high: fls. few (4-8), about 12-merous, 1 in. across, bright mauve-purple, in a dense head, all sessile or subsessile; calyx very hairy, segms. lanceolate; petals acuminate, very hairy outside. Caucasus.

28. *montanum*, Linn. Barren rosette $1\frac{1}{2}$ – $1\frac{3}{4}$ in. diam., the few new rosettes on red pilose peduncles $1-1\frac{1}{2}$ in. long: lvs. closely packed, 60-80 to a rosette, oblanceolate-cuneate, cuspidate, green up to the tip, both surfaces slightly pilose, outer lvs. $\frac{3}{4}$ – $1 \times \frac{1}{4}$ in.; cauline lvs. densely imbricated, lanceolate, tinted with red-brown toward the tip, the lower $1-1\frac{1}{2}$ in. long; fl.-st. including infl. 3-6 in. high: fls. 12-14-merous, bright mauve-red, in a very dense panicle, which is $1\frac{1}{2}$ –2 in. diam.; calyx very hairy, segms. lanceolate; petals $\frac{1}{2}$ – $\frac{5}{8}$ in. long, linear-acuminate. Alps and Pyrenees. Var. *glaciale*, Lagg. (*S. Lehmannii*, Schnittsp.). Lvs. linear-lingulate, base somewhat narrowed, apex bluntly pointed, upper surface weakly glandular-pubescent; cauline lvs. similar but shorter and brown-tipped: fls. dirty red-brown, 10-12-merous; calyx-segms. linear-lanceolate; petals linear. Switzerland.

29. *flagelliforme*, Fisch. Barren rosette $1-1\frac{1}{2}$ in. diam., with the lax new rosettes on long spreading peduncles and the small lvs. not aggregated into a dense erect head: lvs. 40-50 to a rosette, oblanceolate, obscurely cuspidate, surface minutely downy, pale green without a tint of red-brown at the tip, margin ciliate, outer lvs. $\frac{3}{4} \times \frac{1}{4}$ in.; cauline lvs. imbricated, lanceolate,

hairy, lowest about 1 in. long: fl.-st. 3-4 in. high including the infl.: fls. about 12-merous, about 1 in. across, bright red, about 6-8 in a dense head, sessile, or nearly so; calyx densely pilose, segms. lanceolate; petals linear, acuminate, densely glandular-pilose outside. Siberia(?).

30. *Schnittspahnii*, Lagg. (*S. Fünkii*, Lej.). Rosette medium-sized, open, the young ones on straight peduncles $\frac{1}{2}$ -1 in. long: lvs. of rosette ovate-lanceolate, with a short hair point, glabrous, margin white-ciliate, dark green, tip red-brown, keeled beneath; cauline lvs. lanceolate: fl.-st. erect, furrowed, at top slightly winged, white-hairy: fls. brown-rose, later rose, more than 6-merous; petals broadly lanceolate. Switzerland.

31. *Mettenianum*, Schnittsp. & Lehm. (*S. parviflorum*, Lehm. & Schnittsp.). Rosettes flat, $1\frac{1}{4}$ -2 in. diam., the young ones on peduncles 3-4 in. long, which are commonly lvd. below: lvs. ovate-lanceolate, cuspidate, base narrowed, glabrous, margin ciliate, gray-green marbled with grass-green, tip red-brown; cauline lvs. long, straight-acuminate, appressed: fl.-st. spreading, white-hairy, bearing a racemose panicle: fls. rose; petals linear-lanceolate. Cent. Eu. G.M. 57:847.—Allied to *S. tectorum*.

32. *blándum*, Schott (*S. rubicundum*, Schur). Sts. 7-10 in. high, they and the branches of the propagations densely puberulent: rosettes $1\frac{1}{2}$ -2 in. diam.: lvs. of the rosettes obovate-spatulate, short-cuspidate, margin ciliate, glaucous; cauline lvs. spreading, linear-oblong, apiculate-cuspidate, both surfaces softly-puberulent: infl. puberulent and pilose: fls. 12-merous, pale rose; sepals lanceolate, acute; petals lanceolate, acuminate, midnerve deeper colored. Transylvania.

33. *Lamottei*, Bor. Barren rosettes 3-4 in. diam., the copious young rosettes sessile: lvs. obovate-cuneate, cuspidate, glabrous, marginal cilia stiff, outer lvs. $1\frac{1}{4}$ - $1\frac{1}{2}$ x $\frac{1}{2}$ - $\frac{3}{4}$ in., green or faintly glaucous, with only the faintest tint of red-brown at the tip: fl.-st. including infl. often more than 1 ft. high, densely glandular-pilose: fls. 12-16-merous, 1 in. across, pale pink, in a panicle with the main branches often bifid; calyx densely pilose, segms. linear-lanceolate; petals narrow. France.—Has been referred to *S. tectorum* by some authors.

34. *tectórum*, Linn. (*S. robustum*, Jord. & Fourr. *S. purpurascens*, Schott). HOUSELEEK. OLD-MAN-AND-WOMAN. Fig. 3602. Developed barren rosettes 3-4 in. diam., abundantly stoloniferous, the new rosettes crowded and sessile: lvs. 50-60 to a rosette, obovate-cuneate, cuspidate, $1\frac{1}{2}$ -2 or finally 3 x $\frac{5}{8}$ - $\frac{3}{4}$ in., pale green, with a distinct red-brown tip; cauline lvs. oblong-lanceolate, acute: fl.-st. including infl. about 1 ft. high, densely pilose: fls. 11-15- mostly 12-merous, $\frac{3}{4}$ -1 in. across, pale red, in a scorpioid, 10-12-branched panicle 5-6 x 3-4 in.; calyx densely pilose, segms. lanceolate; petals linear, keeled, the keel deeper red. Eu. and Orient. C.L.A. 25, March, p. 54.—Variable. Var. *câpreum*, Hort., is said to have large rosettes which are glaucous and rose-colored; it flowers rarely. Var. *expânsum*, Hort., is said to have broader lvs. and more open rosettes than the type. Var. *pyrenâicum*, Hort., is offered in the trade. Var. *rûbrum*, Hort., has been grown in botanic gardens. Var. *violâceum*, Hort., has been grown in botanic gardens.

35. *Fünkii*, F. Braun; also spelled *Funkii*. Barren rosettes $1\frac{1}{2}$ -2 in. diam. surrounded by a dense circle of young ones on bright red decumbent peduncles, which are 1 in. or more long and densely rosulate at their tip: lvs. 80-100 to a rosette, oblanceolate-cuneate, cuspidate, green and glaucous or slightly pilose when young, outer lvs. $\frac{1}{2}$ - $\frac{3}{4}$ x $\frac{1}{4}$ in., lower cauline lvs. about 1 in. long: fl.-st. including infl. 6-9 in. high, densely pilose: fls. 11-12-merous, about 1 in. across, bright red-purple, in a panicle 2-3 in. diam.; calyx-segms. lanceolate; petals glandular-pubescent outside. S. Eu.—Allied to *S. montanum*.

36. *glâdum*, Tenore (*S. Comollii*, Rota. *S. acuminatum*, Schott, not Jacquem. *S. Schöttii*, Baker, not Schnittsp. & Lehm. *S. Schlehanii*, Schott). Barren rosettes 2-3 in. diam., the copious young ones sessile or nearly so: lvs. oblanceolate-cuneate, cuspidate, glabrous, glaucous, with a slight red-brown tip, outer lvs. $1-1\frac{1}{4}$ x $\frac{3}{8}$ - $\frac{1}{2}$ in.; cauline lvs. oblong-lanceolate, red-tinted, lowest 1-2 in. long: fl.-st. including the infl. 6-12 in. high, densely pilose, at least above: fls. 12-14-merous, about 1 in. across, pale or bright red, in a short compact panicle, 2-3 in. diam.; calyx densely pilose to glandular-pilose, segms. lanceolate; petals somewhat keeled. Cent. Eu.—The synonymy is much involved and by some authorities *S. Comollii* is said to be a hybrid, *S. acuminatum* and *S. Schöttii* synonymous and distinct, and *S. Schlehanii* also distinct, but the differences seem extremely weak.

37. *Verlöttii*, Lamotte. Barren rosettes $1\frac{1}{2}$ -2 in. diam., the new ones nearly sessile: lvs. about 50 to a rosette, oblanceolate-cuneate, cuspidate, glabrous, pale green, faintly glaucous, only the very tip tinged with red-brown, margin stiff-ciliate, outer lvs. $\frac{3}{4}$ -1 x $\frac{1}{4}$ - $\frac{1}{2}$ in.; cauline lvs. oblong-lanceolate, acuminate, lowest about 1 in. long: fl.-st. including the infl. 6-9 in. high: fls. 12-14-merous, $\frac{3}{4}$ - $\frac{7}{8}$ in. across, rose-red, in a panicle 3-4 in. diam., simple glandular-pilose branched, each branch with 8-12 fls.; calyx densely glandular-pilose; petals densely ciliated on the back. Alps of Dauphiné.

38. *atlânticum*, Baker (*S. tectorum* var. *atlânticum*, Ball). Barren rosettes 2-3 in. diam., the young rosettes nearly sessile: lvs. oblanceolate-cuneate, cuspidate, pale green, glabrous when mature, hardly at all tipped with red-brown, outer lvs. $1-1\frac{1}{2}$ in. long, $\frac{1}{2}$ in. broad above the middle; cauline lvs. oblong-lanceolate, noticeably claret-red-tipped: fls.-st. including infl. nearly 1 ft. high: fls. 12-merous, pale red, 1 in. across, in a short panicle, 3-4 in. diam.; calyx densely pilose; petals linear, acuminate. Morocco. B.M. 6055.

3602. Rosette and offsets of a houseleek.—*Sempervivum tectorum*. ($\times \frac{1}{2}$)

39. *triste*, Hort. Barren rosettes 2-3 in. diam.: lvs. oblanceolate-cuneate, cuspidate, glabrous, margin short-ciliate, lower part dull drab-green, the whole upper part bright red-brown; cauline lvs. red-brown throughout, lower ones 2-3 in. long: fl.-st. robust as in *S. tectorum*: fls. about 1 in. across, bright red, in a panicle 6 x 3-4 in.; calyx moderately hairy, deeply tinted with red-brown. Hab.(?).—A rare form allied to *S. tectorum*. Var. *bicolor*, Hort., is offered in the trade.

40. *Greëni*, Baker. Barren rosette about $1\frac{1}{2}$ in. diam., the new ones nearly sessile: lvs. 40-50 to a rosette, oblanceolate-cuneate, cuspidate, glabrous, glaucous with a distinct red-brown tip $\frac{1}{8}$ - $\frac{1}{2}$ in. long, margins decurved ciliate, outer lvs. $\frac{3}{4}$ -1 x $\frac{1}{4}$ in., cauline lvs. much imbricated, lanceolate, hairy, red-tinted, $\frac{3}{4}$ -1 in. long: fl.-st. including infl. 6 in. high: fls. 11-12-merous,

about $\frac{1}{2}$ in. across, pale red, in a panicle $1\frac{1}{2}$ -2 in. diam.; calyx densely pilose; petals densely ciliated. Habitat unknown, possibly the French Alps.

41. *calcàreum*, Jord. (*S. californicum*, Hort.). Barren rosettes about 2 in. diam., young ones nearly sessile: lvs. oblanceolate-cuneate, cuspidate, very glaucous, with a very distinct red-brown tip, glabrous, outer lvs. $1-1\frac{1}{2} \times \frac{3}{8}$ in.; cauline lvs. densely imbricated, oblong-lanceolate, $1-1\frac{1}{2}$ in. long: fl.-st. less than 1 ft. high, including the infl.: fls. 10-12-merous, $\frac{3}{4}$ in. across, pale red in a panicle 3-4 in. long, with 8-12 simple scorpioid branches; calyx densely pilose, segms. lanceolate; petals greenish down the keel, densely ciliate. France on the calcareous alps of Dauphiné.

42. *arvernense*, Lecq. & Lamotte. Barren rosette $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. diam., copiously stoloniferous: lvs. about same number as in *S. tectorum*, oblanceolate-cuneate, cuspidate, bright pale green, glabrous, tips of lvs. with a distinct red-brown blotch $\frac{1}{8}$ - $\frac{1}{6}$ in. long, outer lvs. $1-1\frac{1}{4}$ in. long: fl.-st. including infl. 6-8 in. high, densely pilose: fls. pale pink, in a panicle 2-3 in. long and broad, the lower fls. distinctly pedicelled; calyx-segms. lanceolate; petals linear. France.

43. *Boutignyànum*, Bill. & Gren. Barren rosette 2-3 in. broad, copiously stoloniferous: lvs. oblanceolate-cuneate, cuspidate, glabrous, green, with a distinct, decurrent red-brown tip, outer lvs. $1-1\frac{1}{4}$ in. long; cauline lvs. lanceolate, 1 in. or more long: fl.-st. including infl. 6-8 in. long, short-pilose: fls. 12-14-merous, about $\frac{3}{4}$ in. across, pale rose, in a panicle 2-3 in. diam. which has 8-12 crowded fls.; calyx-segms. lanceolate; petals densely glandular-ciliate. Eu.—Botanically probably a variant of *S. arvernense*.

44. *alpinum*, Griseb. & Schenk. Rosettes 2-3 in. diam.: lvs. of rosettes oblanceolate, base cuneate, apex short-acute, glabrous, green, red-tipped; cauline lvs. oblong to lanceolate, acuminate, sparsely pilose beneath: fls. purple-reddish in a panicle, star-like, expanded; petals 12, linear-lanceolate, glandular-ciliate, dorsally obscurely striate. Eu.—Botanically it is probably only a variant of *S. arvernense*, though referred by some authorities to *S. montanum*.

45. *Boissieri*, Hort. Barren rosette very dense, 2-2 $\frac{1}{2}$ in. diam., composed of about 100 lvs.; new rosettes short-peduncled: lvs. oblanceolate-cuneate, cuspidate, broadest near the middle, glabrous, green, noticeably red-brown-tinted at the tip, $1-1\frac{1}{4}$ in. long; cauline lvs. closely imbricated, red-tinted, oblong to lanceolate: fl.-sts. including the infl. 8-9 in. high.: fls. pale red, 12-14-merous, about 1 in. across, in a panicle about 2 in. diam. Hab.(?).

S. affine, Lamotte, is offered in the trade as having dark green rosettes marked with rose: fls. red. Eu. The botanical description is not available and the species is not treated in recent European floras.—*S. atropurpureum*, Hort., is offered in the trade as having rosettes washed with purple: fls. red.—*S. chrysanthoides*, Hort., is offered in the trade as a form with white fls.—*S. ciliatum*, Craib. Barren rosettes more or less flat, up to $1\frac{1}{4}$ in. diam.: lvs. oblong-lanceolate, more or less acuminate, up to $\frac{3}{4}$ in. long, keeled beneath, conspicuously long white-ciliate toward the apex, pubescent above, outer lvs. red-tinted; cauline lvs. imbricate, tip red-suffused: fl.-sts. about 2 in. high, bearing about 6 subsessile fls.: fls. about 1 in. across, pale green, 9-11-merous; calyx-segms. oblong-lanceolate, acute, glandular-pubescent; petals linear, glandular-pubescent externally. Hab.(?). Grown in botanic gardens.—*S. còchicum*, Hort., is offered in the trade.—*S. commutatum*, Hort., is offered in the trade.—*S. Delpontii*, Hort., is a trade name.—*S. elegans*, Lagg. Rosettes small, about $\frac{1}{2}$ in. diam., the young ones on short shoots forming a mat: lvs. linear-lanceolate, cuspidate, short-villous, weakly covebebed, pale green, slightly ciliated; cauline lvs. numerous, slightly separated, oval-lanceolate, brown toward their tip and tufted ciliate: fl.-st. weak, almost prostrate on the ground during flowering and glandular-hairy; petals oval-lanceolate, acuminate. Switzerland. Not treated in any of the recent Swiss floras but offered in the trade.—*S. hispanicum*, Willd., is a doubtful species with subulate, semi-terete, ciliate, imbricated lvs.; possibly a *Sedum*.—*S. hispanicum*, Pourr., equals *Sedum nicotense*.—*S. hispidulum*, Hort., is offered in the trade.—*S. hispidum*, Hort., is a horticultural name.—*S. humilum*, Hort., is a horticultural name.—*S. kopanikense*, Panc., is said to be related to *S. Heuffeli* by Panic, but is not well known and it is suggested that it is only a form of that species by recent authors. Serbia.—*S. Laggeti*, Hort., is pre-

sumably an error for *Laggeri*.—*S. leucanthemum*, Hort., is probably an error for *leucanthum*.—*S. leucanthum*, Panc., is described as a form with rather small rosettes, 12-merous fls. and white petals, grown in gardens, now questionably referred to *S. tectorum*.—*S. marginatum*, Hort., is offered in the trade.—*S. pilosum*, Hort., is a trade name.—*S. pyrenidicum*, Lamotte, is offered in the trade as having handsomely formed and dark red rosettes. Eu. The botanical description is not available and the recent European floras do not treat this species.—*S. rubens*, Hort., is offered in the trade.—*S. rubrum*, Hort., is offered as having a dark base to the lvs., possibly the same as *S. tectorum* var. *rubrum*.—*S. rupèstre*, Hort., is a trade name, perhaps a form of *S. tectorum*.—*S. Scherzerianum*, Hort., is offered in the trade.—*S. speciosum*, Lamotte, is offered in the trade. Eu. The botanical description is not available and none of the recent European floras mentions it.—*S. spinosum*, Hort., is a trade name.—*S. spinulifolium*, Hort., is offered in the trade and also occurs in botanic gardens.—*S. Thomsonii*, Lindsay (*S. arachnoideum* $\times$ *S. tectorum*), is offered in the trade; no description of the hybrid is available.—*S. umbicolum*, Hort., is a trade name. Var. *spinosum*, Hort., is a trade name perhaps the same as the plant offered in the trade as *S. spinosum*.—*S. virbicum*, C. Smith. Shrubby: st. erect, 3 ft. high, simple, stout, covered with lf.-scars: lvs. many, rosulate at the top of the st., 4-6 $\times$ $1\frac{1}{2}$ in., narrowly spatulate, cuspidate, very thick, pale green, margins erose-serulate, sessile or short-petioled; panicle very large, pyramidal, 3 ft. high and nearly as broad, many-branched; fls. 10-merous, pale yellow, $\frac{3}{4}$ in. across; calyx cup-shaped; petals lanceolate, acute. Canary Is. B. M. 7893. Belongs to the same group as *S. arboreum*. A very showy species but tender.—*S. violaceum*, Hort., is offered in the trade; possibly the same as *S. tectorum* var. *violaceum*.—*S. Zelbori*, Schott. Barren rosette more than 2 in. diam., the young ones borne on densely puberulent peduncles: lvs. spatulate-ob-lanceolate to spatulate-lanceolate, apex apiculate and purple, short-ciliate, both surfaces densely puberulent, glaucous; cauline lvs. smaller, linear-lanceolate, apiculate and puberulent: fl.-st. minutely glandular and densely hirsute: fls. 11-12-merous, pale yellowish; calyx-segms. lanceolate; petals linear-lanceolate, acuminate, viscid hirtellous dorsally. Serbia. By some authorities referred to *S. Pittonii*, by others to *S. globiferum*; apparently distinct from both of them.

F. TRACY HUBBARD.

SENEBIÈRA (after Johann Senebier, a naturalist of Geneva). *Cruciferae*. Annual or biennial herbs, very diffusely branched from the ground, hardy: lvs. alternate, entire or pinnatisect; racemes short; fls. minute, white, rarely purple; sepals short, spreading; stamens free: silique small, didymous, laterally compressed; valves shut, subglobose, rugose or crested.—About 15 species in the temperate and warmer regions of the world.

The oldest name of the genus and the one now accepted by those following the International rules is *Coronòpus* (Greek *crow* and *foot*, alluding to the form and arrangement of the deeply cut lvs.). *C. didymus*, Smith (*Senebiera didyma*, Pers. *S. pinnatifida*, DC. *Lepidium didymum*, Linn. *Caràra didyma*, Brit.). Plant 6-12 in. high: lvs. 1-2-pinnately parted: fls. white, small, numerous: pods notched at the apex, rough-wrinkled. Widely distributed as a cosmopolitan weed.

SENÈCIO (Latin name for plants of this genus, ultimately from *senex*, "old man," said to be in allusion to the hoary pappus). *Compositae*. **GROUNDSEL**. A various group, some of the herbaceous members of which are grown as border plants for their mostly yellow heads and sometimes for the striking habit; others are climbers, grown mostly indoors, as the so-called German ivy; the shrubby kinds are little known in cultivation.

Senecio is probably the largest genus of plants, comprising some 1,200 species in all parts of the world. A genus comprising so many members and being so widely distributed is necessarily variable and therefore practically impossible of concise definition. A distinguishing mark of the *senecios* lies in the character of the involucre,—scales or bracts in one series, and usually reinforced at the base by shorter scales or bracteoles that give the head the appearance of having a small calyx. Heads usually radiate, the ray-florets pistillate and fertile, but sometimes the rays absent and then the head is homogamous (florets all of one kind, i. e., perfect); disk-florets tubular, 5-toothed; style-branches subterete, truncate, rounded-obtuse, occasionally terminated by a small penicillate tuft of hairs; receptacle usually naked: achenes mostly terete and ribbed; pappus of soft whitish, often copious bristles. Most of

the senecios are yellow-rayed. Of the vast number of species, very few have gained prominence in horticulture.

To Senecio belong the genera known to gardeners as Jacobæa, Kleinia, and Cineraria. The latter is a Senecio, although the florist's cineraria is described under that name in Vol. I of this work. Benthams & Hooker refer to Senecio the genus Cacalia, which is kept distinct by American botanists. Hoffman (in Engler & Prantl's Natürl. Pflanzenfamilien) refers the garden genus Emilia to Senecio, but keeps Ligularia (including Farfugium) and Cineraria (not the florist's cineraria) distinct. See Emilia; also Ligularia.

If the greenhouse cineraria (which is technically a Senecio as understood by Benthams & Hooker) is omitted, the most popular species are *S. mikanioides* or German ivy, *S. elegans* or purple ragwort, *S. pulcher*, and *S. Cineraria*, one of the plants commonly known as dusty miller. Various other plants are known as dusty miller, and one of them, *Artemisia Stelleriana*, is sometimes confounded with *Senecio Cineraria*. Most other species are of very minor importance to the horticulturist. Several species are found in the European trade, and of the sixty or more species native to the United States and Canada, about a half dozen have been offered by dealers in native plants, but they are practically unknown horticulturally. Most of the species are wholly herbaceous, but in South Africa, Australia, Central and South America many species are shrubby. Some species are even arborescent; others are climbers. In South Africa and the Canaries is a small series of species that has been separated as Kleinia, distinguished mostly by their habit, being for the most part fleshy shrubs or herbs, with terete or angular stems and whitish or pale yellow rayless flowers. Species of this group are sometimes seen in collections of succulents. *S. vulgaris*, Linn., from Europe, is a common annual weed in various parts of this country.

Since senecios afford both greenhouse and hardy border plants, it is impossible to give general cultural directions. The species are not difficult to manage, however, and most of them propagate readily by means of greenwood cuttings and seeds; the hardy species may be divided. Most of the tender species require coolhouse conditions.

KEY TO THE SPECIES.

- A. *St. and lvs. more or less fleshy: heads rayless.*
- B. *Lvs. flat, lacinate.*..... 1. *articulatus*
- BB. *Lvs. terete, undivided.*..... 2. *radicans*
- AA. *St. and lvs. not fleshy: heads rayless or radiate.*
- B. *Habit climbing.*
- C. *Heads rayless.*..... 3. *mikanioides*
- CC. *Heads radiate.*
- D. *Plants pubescent.*..... 4. *scandens*
- DD. *Plants glabrous.*
- E. *Lvs. not conspicuously auricled at the base.*..... 5. *macroGLOSSUS*
- EE. *Lvs. conspicuously auricled at the base.*..... 6. *auriculatissimus*

BB. *Habit not climbing.*

C. *Annuals.*

- D. *Lvs. 1-3 cm. long, deeply pinnatifid.*..... 7. *elegans*

- DD. *Lvs. 4-10 cm. long, lobate-dentate.* 8. *pulcher*

CC. *Perennials.*

- D. *Lvs. pinnately veined.*

- E. *The st. herbaceous: plants not densely white-tomentose.*

- F. *Rays purple.*..... 9. *grandiflorus*

- FF. *Rays yellow.*

- G. *All lvs. undivided.*

- H. *Plants glabrous: involucre bracts not black-tipped.*

- I. *Lvs. glaucous.*..... 10. *Doria*

- II. *Lvs. not glaucous.*..... 11. *macrophyllus*

- HH. *Plants more or less pubescent.*

- I. *Involucre bracts black-tipped.*

- J. *Pubescence floccose-woolly.*

- K. *Lower lvs. closely dentate.*..... 12. *Doronicum*

- KK. *Lower lvs. remotely denticulate.*..... 13. *lugens*

- JJ. *Pubescence of hirsute, jointed hairs.*..... 14. *exaltatus*

- II. *Involucre bracts not black-tipped.*..... 15. *saxifragoides*

- GG. *All lvs. or some of them divided.*

- H. *St.-lvs. once-pinnate.*

- I. *Height of plants 6 in. to 3 ft.: basal lvs. undivided.*

- J. *Involucre bracts 13, usually pubescent.*..... 16. *Bolanderi*

- JJ. *Involucre bracts 21, glabrous.*..... 17. *aureus*

- II. *Height of plants 4-7 ft.: lvs. all pinnatifid.*

- J. *Infl. corymbose.*..... 18. *Faberi*

- JJ. *Infl. paniculate.*..... 19. *tanguticus*

- HH. *St.-lvs. 2-3-pinnatisect.*..... 20. *Jacobæa*

- EE. *The st. herbaceous or distinctly woody: plants usually white-tomentose throughout (sometimes glabrous in S. Douglasii).*

- F. *Heads solitary.*..... 21. *uniflorus*

- FF. *Heads several to many.*

- G. *Lvs. all undivided.*

- H. *Shape of lvs. oblanceolate.*

- I. *Sts. not leafy.*..... 22. *fastigiatus*

- II. *Sts. leafy.*..... 23. *Palmeri*

- HH. *Shape of lvs. oblong to ovate; glabrous above.*..... 24. *Greyii*

- GG. *Lvs. all or some of them divided.*

- H. *Lf.-divisions broad, obtuse; bracteoles inconspicuous.*..... 25. *Cineraria*

- HH. *Lf.-divisions narrow, acute; bracteoles conspicuous.*..... 26. *Douglasii*

- EEE. *The st. woody: shrubs or under-shrubs, not white-tomentose.*

- F. *Length of lvs. 3-5 in.*

- G. *Rays yellow.*..... 27. *magnificus*

- GG. *Rays white.*..... 28. *Kirkii*

- FF. *Length of lvs. 6-18 in.*..... 29. *grandifolius*

- DD. *Lvs. palmately veined.*

- E. *Heads rayless.*..... 30. *Prainianus*

- EE. *Heads radiate.*

- F. *St. woody.*

- G. *Lvs. 4-20 cm. broad: heads numerous.*..... 31. *Petasitis*

- GG. *Lvs. 1-3 cm. broad: heads solitary.*..... 32. *Heritieri*

- FF. *St. herbaceous.*..... 33. *cruentus*

1. *articulatus*, Schz. Bip. (*Kleinia articulata*, Haw.).
CANDLE PLANT. Plant branching, glabrous and fleshy, 1-2 ft. high, the branches swollen at intervals: lvs. flat and fleshy, petiolate, lacinate or runcinate, with acuminate lobes: heads discoid and all the florets perfect, white, in small corymbs on naked peduncles: achenes downy. S. Afr.—Perhaps the commonest kleinia in cult., being grown with coolhouse succulents. S.

(*Kleinia*) *Anteuphorbium*, Schz. Bip., is sometimes seen in collections, although it is not known to be in the American trade. It is a glabrous shrub 3–4 ft. high, with fleshy sts. constricted at the joints, small, erect, fleshy, entire lvs. that are decurrent on the st., and solitary cylindric yellow-fl. heads (with rose tinge) an inch long. B. M. 6099. According to J. D. Hooker, this

3603. *Senecio radicans*.

plant "is one of the oldest Cape plants in cult. having, according to Dodonaeus, been brought to Eu. in 1570, and cult. in England in Gerard's garden in 1596. The name *Anteuphorbium* was given because of its being a reputed antidote against the acrid poison of the Cape *Euphorbium*." The names *Kleinia spinulosa*, *K. pendula*, and *K. suspensa* have appeared in the American trade, but they are unidentifiable.

2. *radicans*, Schz. Bip. (*Cacalia radicans*, Linn. f. *Kleinia radicans*, Haw.). Fig. 3603. Sts. prostrate, readily rooting from the nodes: lvs. fleshy, cylindrical, straight or somewhat curved, 1 in. or less in length, $\frac{1}{4}$ in. thick, acute, narrowed at the base into a short petiole: peduncle terminal, bearing a single rayless head. S. Afr.—A desirable plant for the rockery; it grows freely among cacti and other fleshy plants.

3. *mikanoides*, Otto (*S. scandens*, DC.). GERMAN IVY. Fig. 3604. Slender and glabrous, tall-twining: lvs. ovate or deltoid-ovate in outline, mostly with a deep basal sinus, sharply 5–7-angled or angle-lobed: heads small, discoid, yellow, in close clusters on axillary and terminal branches; bracts of the involucre shorter than the disk-fls. S. Afr. G. 35:343.—Very common conservatory and window-garden plant, easily prop. by cuttings.

4. *scandens*, Buch.-Ham., not DC. A hardy plant with woody climbing sts. reaching a height of several feet: branches slightly hirsute: lvs. short-petiolate, elliptic-lanceolate in general outline, undivided or bearing two or more divisions at the base of the blade, triangular-dentate, grayish green and finely pubescent on both surfaces: infl. a terminal panicle; heads radiate, rays commonly 8, yellow. China. R.H. 1909, p. 407.—Intro. by de Vilmorin, Verrières-le-Buisson, France.

5. *macroglossus*, DC. CAPE IVY. An herbaceous glabrous climbing perennial: lvs. petiolate, deltoid-hastate, 1–1½ in. long and broad, usually with 2 salient acuminate basal lobes, entire or subdentate, cordate to almost truncate at the base: flowering branches 1–3-headed: heads radiate with 8–12 yellow rays; disk-fls. 40–50: achenes glabrous. S. Afr. G. 26:26.—A coolhouse climber.

6. *auriculatissimus*, Brit. A perfectly glabrous climbing perennial, freely branching with divaricately spreading branches: lvs. petiolate, transversely oblong to subreniform, 2–3 in. broad, coarsely crenate-dentate, bright green above, paler beneath; petioles 1–2 in. long, slender, channelled above, abruptly dilated at the base into 2 broad auricles completely clasping the st.: heads radiate, about 1 in. diam., disposed in loose terminal corymbose cymes; ray-fls. about 13, rays yellow:

achenes 5-ribbed, puberulent along the ribs. Brit. Cent. Afr. G. C. III. 27:133, desc. B.M. 7731.—On account of the peculiar foliage and bright yellow fls. it is a striking plant and well worthy of more general cult.

7. *élegans*, Linn. (*S. purpureus*, Hort. *Jacobaea elegans*, Moench). PURPLE RAGWORT. Annual, viscid-pubescent, erect or diffuse, 1–2 ft. high: lvs. various, mostly oblong in outline, pinnate, lobed or toothed, the sinuses chiefly broad and rounded, clasping at the base. heads in loose corymbs, the rays purple; disk-fls. yellow. S. Afr. B.M. 238. Var. *erectus*, Harv. St. slender but erect: lvs. pinnate or 2-pinnatifid.—*S. elegans* is an old garden plant. A common form of it has double fls. Var. *álbus*, Hort., has white fls.

8. *púlcher*, Hook. & Arn. Robust, 2–4 ft. high, white-cobwebby: st. simple or nearly so and scarcely leafy: lvs. oblong-lanceolate, 4–10 in. long, thick, shallow-lobed and crenate-toothed: heads 2–3 in. across, with many long, red-purple rays and a yellow disk. Uruguay and Argentina. B.M. 5959. R.H. 1877, p. 94; 1896, p. 329. Gn. 49, p. 122. G.M. 40:745. G. 31: p. 489, desc.—A very bold species, with striking erect habit and large fls. in summer. Perennial, although it has been described as annual. In protected places and well-drained soils, it is hardy in S. New England.

9. *grandiflorus*, Berg. (*S. venustus*, Ait.). An herbaceous perennial 4–5 ft. high: st. simple or sparingly branched, virgate, striate, glabrous or nearly so, rather leafy except toward the infl.: lvs. sessile, pinnately parted into linear divisions with revolute margins, glabrous or sparingly pilose: heads numerous, radiate, strongly calyculate, disposed in a loose nearly naked corymbose cyme; rays purple; disk-fls. yellow: achenes striate, glabrous or puberulent in the furrows. S. Afr. B.R. 901. Var. *álbidus*, Harv. (*S. álbidus*, Mey.). Both ray- and disk-fls. pale or whitish.

10. *Dòria*, Linn. Erect, 3–4 ft. high: radical lvs. oval-oblong or oblanceolate, 6–15 in. long, dentate, glabrous and glaucous, gradually narrowed into a winged petiole; st.-lvs. oblong-lanceolate, sessile and somewhat decurrent: heads yellow, with 5 or 6 rays. Eu.—Hardy perennial.

11. *macrophyllus*, Bieb. (*Jacobaea macrophylla*, Mey.). A stout herbaceous perennial, 3–4 ft. high, glabrous or nearly so: lower lvs. obovate-oblong or oblanceolate, 6–18 in. long, 1–4 in. broad, gradually narrowed into a winged petiole, pale green, not glaucous; upper st.-lvs.

3604. *Senecio mikanoides*, usually called German ivy. ($\times \frac{1}{6}$)

sessile, semi-amplexicaul and somewhat decurrent on the st.: heads radiate, disposed in a terminal compound corymbose cyme. Eu.—Closely related to the preceding. Not infrequent in European gardens and occasionally offered in trade catalogues.—Not the same as *Ligularia macrophylla*, DC.; see supplementary list.

12. *Doronicum*, Linn. LEOPARD'S BANE. A hardy herbaceous perennial, floccose-tomentulose to glabrous: lvs. thickish, ovate to lanceolate, 2-7 in. long, $\frac{1}{2}$ - $1\frac{1}{2}$ in. broad, the lower usually rather coarsely dentate and narrowed into a winged petiole, the upper much reduced, sessile and entire: heads few, large, including the bright yellow or orange-colored rays 1-2 $\frac{1}{2}$ in. diam.; bracts of the involucre as well as the bracteoles attenuate, black-tipped: achenes striate, glabrous. S. Eu.—Frequently offered by European dealers, but seldom grown in American gardens.

13. *lucens*, Richards. An herbaceous perennial, floccose-woolly when young but becoming nearly or quite glabrous: st. practically naked above: lvs. oblong-obovate to lanceolate, $1\frac{1}{2}$ -6 in. long, $\frac{1}{2}$ -1 in. broad, repand-denticulate, the lower narrowed into a winged petiole: heads relatively few, radiate, including the yellow rays $\frac{1}{2}$ - $1\frac{1}{4}$ in. diam.; bracts of the involucre as well as the subtending bracteoles acute, black-tipped: achenes striate, glabrous.

W. N. Amer. in the Rocky Mts. from Mont. to Alaska.—A species very little known horticulturally.

14. *exaltatus*, Nutt. An herbaceous perennial: st. simple, erect, 8 in. to 3 ft. high, striate, glabrous, or somewhat pubescent with long flaccid jointed white hairs: lower lvs. oblong-ovate to lanceolate, including the narrowly winged petiole 3-8 in. long, $\frac{1}{2}$ -2 in. broad, entire to unequally dentate, glabrous or more or less crisp-hirsute; upper st.-lvs. much reduced, sessile: heads nearly $\frac{1}{2}$ in. high, few to many, radiate with yellow rays. Mont. to Ore., Wash. and adjacent Canada.—Little known in horticulture.

15. *saxifragoides*, Hook. f. A perennial herb from a stout rootstock: st. about 1 ft. high, branched, covered at the base with a long silky-woolly tomentum and clothed above with white hairs intermixed with purple setae: radical lvs. petiolate, oblong-elliptic to nearly orbicular, 3-5 in. long, $1\frac{3}{4}$ -4 in. broad, denticulate, appressed-villous, setose near the margin, and more or less glabrous above, hoary-woolly beneath: heads several, corymbose, radiate; rays 18-20, yellow; disk-fls. numerous: achenes glabrous. New Zeal. B.M. 8394.—Intro. into England in 1908 and brought to flower two years later at Kew; it is a strikingly beautiful plant worthy of cult.

16. *Bolanderi*, Gray. A slender herbaceous perennial: st. ascending or erect from a creeping rootstock, 6-20 in. high: radical and lower st.-lvs. undivided and crenately lobate-dentate to pinnately divided into oblong-obovate

to almost rotund divisions, glabrous above, usually pubescent beneath, including the petiole 2-6 in. long, $\frac{1}{2}$ - $1\frac{1}{4}$ in. broad: heads few, radiate, disposed in a corymbose cyme; involucre of about 13 bracts, commonly tawny-pubescent; ray-fls. 5-8, rays yellow; disk-fls. 25-40: achenes glabrous. Calif. and Ore., near the coast.

17. *aureus*, Linn. GOLDEN RAGWORT. Fig. 3605. An herbaceous perennial: sts. 1 to several from a rootstock, 1-2 ft. high, glabrous or not infrequently white-tomentulose in the lf.-axils, along the margins of the petioles, and in the infl.: lower lvs. petiolate, undivided and rotund-ovate, somewhat triangular-ovate to oblong-ovate, $\frac{1}{2}$ -6 in. long, two-thirds to nearly or quite as broad, crenate to doubly serrate-dentate, usually deeply cordate at the base, green on both surfaces or tinged with purple beneath, glabrous or occasionally slightly tomentulose and soon glabrate; petioles $\frac{1}{2}$ -10 in. long; st.-lvs. variable, petiolate to sessile and amplexicaul, lyrate to pinnatisect, reduced toward the infl. sometimes to linear entire bracts: infl. a terminal several-to many-headed corymbose cyme; heads $\frac{1}{3}$ - $\frac{1}{2}$ in. high, radiate; involucre campanulate, calyculate, glabrous or occasionally slightly tomentulose; bracts of the involucre 13-21, linear, acute; ray-fls. 8-12, rays yellow; disk-fls. numerous: achenes glabrous. Lab. to Ga., west to N. D. and Ark. B.B. 3:544.—Frequently grown in American gardens.

18. *Fäberi*, Hemsl. A stout coarse herb, glabrous or glabrescent: sts. several, 4-5 ft. high, striate-angled, hollow: lvs. pinnatifid, coarsely dentate, expanding at the base into 2 large auricles partially clasping the st.; the lowermost lvs. becoming 2 ft. in length: infl. a many-headed corymbose cyme 6-8 in. diam.; heads radiate with 3-5 deep yellow rays; disk-fls. 8-12, yellow.

W. China. G.C. III. 40:43, desc.—Originally intro. by Veitch & Sons, and more recently by E. H. Wilson, who has traveled in China.

19. *tanguticus*, Maxim. (*S. Henryi*, Hemsl.). A tall stout herbaceous perennial, glabrous or nearly so: st. 6-7 ft. high, branched above, leafy: lvs. broadly ovate or deltoid in general outline, 5-7 in. long and broad, pinnately divided into lanceolate coarsely and remotely toothed divisions, dark green above, paler beneath; petioles of the lower lvs. long and dilated below into an amplexicaul base: heads very numerous, radiate, disposed in a terminal pyramidal panicle; ray-fls. 3 or 4, rays yellow; disk-fls. 3 or 4, corolla-lobes revolute. W. China. B.M. 7912. Gn. 64, p. 237.—A con-

3607. *Senecio cineraria*—the typical form with rays.

3606. *Senecio cineraria*. One of the plants known as dusty miller.

3605. *Senecio aureus*.

spicuous and attractive species; flowers in Sept. and Oct. Frequently offered by American dealers.

20. *Jacobæa*, Linn. TANSY RAGWORT. STINKING WILLIE. An erect biennial or perennial herb: st. 1-3 ft. high, leafy: basal lvs. petiolate, sublyrate; st.-lvs. sessile, $1\frac{1}{2}$ -6 in. long, $\frac{3}{4}$ -2 $\frac{3}{4}$ in. broad, 2-3-pinnatisect: heads numerous, radiate with yellow rays. Eu. Naturalized in N. E. Amer. along the coast.—Occasionally cult. in gardens.

3608. *Senecio Douglasii*. ($\times \frac{1}{2}$)

21. *uniflorus*, All. A low herbaceous perennial, densely white-tomentose throughout: st. 2-5 in. high, usually terminated by a solitary head: lvs. mostly radical, spatulate to oblong, entire to incised-dentate, 1-2 in. long, $\frac{1}{2}$ in. or less broad: heads radiate; rays yellow. S. Eu.—An alpine plant, occasionally grown in Amer. and desirable for the rockery.

22. *fastigiatus*, Nutt. An herbaceous perennial, floccose-tomentulose throughout, somewhat glabrate: st. 1-2 ft. high: lower lvs. narrowly oblong-oblancoate, including the long slender petiole 3-6 in. long, $\frac{1}{2}$ in. or less broad, entire or nearly so, usually with revolute margins; upper st.-lvs. much reduced: heads radiate; commonly several in a terminal corymbose cyme; ray-fls. about 8, rays yellow. Idaho, Ore., and Wash.

23. *Pálmeri*, Gray. Suffrutescent, about 3 ft. high, branching, densely white-tomentose throughout: lvs. oblong-oblancoate, $1\frac{1}{2}$ -4 in. long, $\frac{1}{4}$ -1 in. broad, entire to slightly sinuate-dentate, narrowed below into a more or less winged petiole: heads about $\frac{1}{2}$ in. high, radiate, disposed in terminal subcorymbose cymes; ray-fls. 12-18, rays yellow. Guadalupe Isl., Low. Calif.—Intro. by Franceschi, Santa Barbara.

24. *Grèyii*, Hook. f. A small spreading shrub $1\frac{1}{2}$ -3 ft. or more high: branchlets, under surface of lvs., and petioles densely covered with a soft white tomentum: lvs. oblong or oblong-ovate, $1\frac{1}{2}$ -3 $\frac{1}{2}$ in. long, obtuse, entire, nearly glabrous on the upper surface: heads radiate, disposed in large terminal corymbose cymes; ray-fls. 12-15, rays golden yellow. New Zeal. Gn. 54, p. 434.—A hardy perennial grown in the gardens of Veitch & Son, Exeter, England.

25. *Cinerària*, DC. (*Cinerària maritima*, Linn. *Senecio acanthifolius*, Hort.). Figs. 3606, 3607. Perennial, $2\frac{1}{2}$ ft. or less tall, branching from the base, very white-woolly throughout: lvs. pinnatifid, with oblong and obtuse segms.: heads usually radiate, $\frac{1}{4}$ - $\frac{1}{2}$ in. high, disposed in small, compact cymes. F.M. 1872:52. Var. *candidissimus*, Hort., has very white foliage. Var. *aureo-marginatus*, Hort., has lvs. bordered with orange-yellow.—*S. Cineraria* is an old-fashioned garden plant, sometimes known as "dusty miller," and at the present time it is much used in American gardens for ribbon-beds and margins; the commoner "dusty miller" is *Lychnis Coronaria*, and still another one is *Artemisia Stelleriana*.

26. *Douglasii*, DC. Fig. 3608. A tufted perennial, white-floccose tomentose throughout to essentially glabrous: sts. 1-3 ft. high, distinctly woody below, leafy: lvs. undivided and linear or narrowly linear-lanceolate to pinnatifid with few to several linear-attenuate divisions: infl. a terminal open corymbose cyme; heads about $\frac{1}{2}$ in. high, radiate; involucre campanulate, composed usually of 21 bracts subtended by numerous attenuated bracteoles; ray-fls. commonly 13, rays yel-

low; disk-fls. 50-70: achenes pubescent. S. Utah to Ariz., west to Calif., and northern Lower Calif.—First collected in Calif. by Douglas in 1833.

27. *magnificus*, F. Muell. A tall stout undershrub, glabrous and glaucous; st. sparingly branched, terete, leafy: lvs. thickish, sessile, oblong-lanceolate or oblanceolate, 2-6 in. long, coarsely remotely and saliently dentate: heads relatively few, radiate, disposed in terminal corymbose cymes; ray-fls. 8-12, rays golden yellow; disk-fls. numerous. Austral. B.M. 7803.—Intro. by J. H. Maiden in 1899 and brought to flower at Kew in Oct., 1900.

28. *Kirkii*, Hook. f. (*S. glastifolius*, Hook. f. *Solidago arborescens*, A. Cunn.). An erect stoutly branching shrub, 7-15 ft. high, glabrous throughout: lvs. variable, narrowly oblanceolate to oblong-obovate, 2-5 in. long, $\frac{1}{3}$ -2 in. broad, entire or sinuate-dentate, narrowed into a slender petiole or cuneate at the base: heads numerous, large, radiate, disposed in a terminal compound corymbose cyme; ray-fls. 10-12, rays $\frac{3}{4}$ -1 in. long, white; disk-fls. yellow. New Zeal. B.M. 8524.—The white rays and yellow disk-fls., and the profuseness of bloom, render this species a very unusual member of its genus; it should prove an interesting plant in horticulture.

29. *grandifolius*, Less. (*S. Ghiesbreghtii*, Regel). A leafy shrub, 3-15 ft. high: lvs. petiolate, ovate or ovate-oblong, 6-18 in. long, one-half to two-thirds as broad, acute, sinuate-dentate and remotely callous-denticulate, dark green and glabrous or nearly so above, somewhat tawny-tomentulose beneath, cordate to rounded at the base; petioles stout, $1\frac{1}{2}$ -5 in. long: infl. a terminal many-headed subcorymbose cyme; heads radiate; ray-fls. about 5, rays yellow; disk-fls. about 10: achenes glabrous. S. Mex. Gt. 9:296. J.H. III. 60:313.—An attractive leafy winter-flowering shrub.

30. *Prainianus*, Berger. Shrub, about 3 ft. high: lvs. long-petiolate, ovate-deltoid, or suborbicular, 5-7 in. broad, palmately 7-9-lobed, cordate at the base, somewhat hispid above, pubescent on the prominent nerves beneath: infl. a terminal much-branched drooping panicle; heads rayless. S. Mex. G.C. III. 50, p. 82

3609. The florist's cineraria, a very large show specimen.—Supposed to have been developed from *Senecio cruentus*.

(whence the above description, and from which the plant would seem to be a *Cacalia*).—Said to be a very ornamental plant resembling the following species.

31. *Petasitis*, DC. (*Cinerària Petasitis*, Sims). VELVET GROUNDSEL. CALIFORNIA UMBELIFEROUS. A robust perennial 3-8 ft. high, somewhat hirsute-velutinous on the younger parts: lvs. petiolate, broadly ovate or suborbicular, 2-7 in. broad, cordate to subtruncate at the

base, sinuately 9-13-lobed, callous-denticulate, hirtellous above, more or less grayish-tomentose beneath; infl. a terminal many-headed panicle; heads radiate, about $\frac{1}{2}$ in. high; ray-fls. usually 5, rays yellow; disk-fls. about 15; achenes glabrous. S. Mex. B.M. 1536. G.W. 9, p. 137.—A useful plant for winter decoration, and rather common in greenhouse cult.

32. *Heritièri*, DC. A low suffruticose perennial, seldom more than 1 ft. high; st. ascending or erect, at first white-tomentose, later glabrate; lvs. petiolate,

3610. *Senecio cruentus* var. *Webberianus*, one of the early forms of the garden cineraria.

suborbicular, $\frac{1}{2}$ - $1\frac{3}{4}$ in. broad, 5-7-lobed, araneous-tomentulose in the young stages above but soon glabrate, densely and permanently white-tomentose beneath; heads radiate, mostly solitary on an elongated nearly naked peduncle; ray-fls. about 13, rays purple. Teneriffe. B.M. 53 (as *Cineraria lanata*). G.C. III. 50:333.—First brought into cult. about 1793.

33. *cruentus*, DC. (*Cineraria cruenta*, Mass.). Short-stemmed perennial, floccose-woolly: lvs. large, cordate-ovate to cordate-triangular, angled or undulate and sinuate-toothed, rather long-stalked; fls. purple-red. Canary Isls. B.M. 406.—The supposed parent of the florists' cinerarias (Fig. 3609), for discussion of which see p. 771, Vol. II. According to The Garden, March 1, 1890, it was in 1777 that the type of the florists' cineraria was first intro. from the Canary Isls. by Masson. Whether the present highly improved races of cinerarias are direct descendants of *S. cruentus* or the result of hybridization is not now determined. The garden or modified race began to develop very early. Fig. 3610 is *Cineraria Webberiana*, Paxt. (*Senecio cruentus* var. *Webberianus*, Hort.), copied from The Garden, which "was raised in the spring of 1841 by Mr. Smithers, gardener to Mr. R. Williams, and has bright green leaves and boldly coloured flowers—a form that would give delight in these days." It is said that the first double cineraria is thought to have been Mrs. Thomas Lloyd, certificated in March, 1880.

Several species which have been described under the genus *Senecio*, some being of rather recent intro., seem to the writer to be more satisfactorily treated under the genus *Ligularia*. Among those appearing to be of considerable importance from a horticultural

standpoint are the following: *Ligularia chivorum*, Maxim. (*Senecio chivorum*, Maxim.). A robust herbaceous perennial, 4 ft. high, at first tawny-pubescent, glabrate; radical lvs. long-petiolate, reniform or subrotund, sometimes 20 in. diam., sharply mucronate-dentate; heads large, many-fld.; radiate with orange-yellow rays; disk-fls. dark brown. Japan and China. G.M. 51:675. Flowers Aug. and Sept.—*Ligularia macrophylla*, DC. (*Cineraria macrophylla*, Ledeb.—*Senecio Ledebourii*, Schz. Bip.); for description see p. 1859, Vol. IV.—*Senecio Pardonii*, Turill. St. erect, sulcate, densely tawny-pubescent; radical lvs. long-petiolate, broadly orbicular, about 12 in. long, 15 in. broad; infl. paniculate; heads rayless. China. Intro. into England in 1914 by Veitch & Sons. Not yet known in American gardens. Needs further study.—*Ligularia stenocéphala*, Greenm. comb. nov. (*Senecio stenocéphalus*, Maxim. Bull. Acad. St. Petersb. 16:218. 1871. *S. cacaliaefolius* var. *stenocéphalus*, Franch.). Radical lvs. long-petiolate, reniform, about 9 in. long, 16 in. broad, deeply cordate, coarsely toothed, glabrous on both surfaces; infl. racemose. 12 in. or more long, $2\frac{1}{2}$ in. wide at the base; heads radiate; ray-fls. 1-6, rays yellow; disk-fls. 5-6. China. B.M. 8472.—*Ligularia Veitchiana*, Greenm. comb. nov. (*Senecio Veitchianus*, Hemsl. G.C. III. 38:212. 1905). A very stout perennial herb with simple flowering st. 3-6 ft. high; radical lvs. 15-16 in. long, 10-11 in. broad, sharply dentate; heads very numerous, about $2\frac{1}{2}$ in. diam.; ray-fls. 10-12, rays yellow. China. G.M. 50:741.—*Ligularia Wilsoniana*, Greenm. comb. nov. (*Senecio Wilsonianus*, Hemsl. G.C. III. 38:212. 1905). GIANT GROUNDSEL. A robust herbaceous perennial with a flowering st. 3-5 ft. high; radical lvs. long-petiolate, the blade reniform-cordate, 10-20 in. long, 9-10 in. broad, sharply dentate; infl. an elongated columnar-like spike, branched at the base; heads very numerous, radiate, about 1 in. diam.; ray-fls. 6-8, rays yellow. China. G. 34:113. G.C. III. 42:201. This and the preceding one are desirable plants for ditch-borders and bog-gardens.

J. M. GREENMAN.

SENNA: *Cassia*. S., Bladder: *Colutea*.

SENSITIVE FERN: *Onoclea sensibilis*. S. Plant: *Mimosa pudica*.

SEQUOIA (after Sequoyah, otherwise George Guess, a Cherokee half-breed of Georgia, about 1770-1843, originator of the Cherokee alphabet). *Pinaceæ*. BIG TREES OF CALIFORNIA. REDWOOD. Tall massive often gigantic forest trees, grown as ornamental evergreens in Europe, in California, and to a limited extent in the eastern states; of chief interest because of their great age and large size. *S. gigantea* is the most massive of all trees, although exceeded in girth by several others, notably the African baobab. *S. sempervirens* holds the record as the tallest tree in the world, at least so far as actual measurements have been made, one specimen in Humboldt County, California, measuring 340 feet, according to Sargent. Greater heights assigned to species of *Eucalyptus* were erroneous (see note under *E. amygdalina* var. *regnans*, Vol. II, p. 1157).

Large trees with thick red fibrous and deeply grooved bark: heartwood dark red, soft, durable, straight-grained; sapwood thin and nearly white; lvs. persistent, alternate, linear or awl-shaped or scale-like, often dimorphic: fls. monocious; staminate catkins axillary and terminal, each of the numerous spirally arranged stamens bearing 2-5 pollen-sacs; pistillate catkins terminal, composed of many spirally arranged scales, each with 4-7 ovules at base; cone woody, persistent, the divergent scales widened at summit which is rhomboidal, wrinkled, and with a depressed center; seeds flattened; cotyledons 2.

sempervirens, Endl. CALIFORNIA REDWOOD. Fig. 3611 (adapted from Amer. Forestry xx:323). Tree 100 to 340 ft. high, with trunk 10-25 ft. in diam. and often clear of limbs for 100 ft. in mature specimens, the narrow crown with horizontal or downward-sweeping branches: lvs. linear, mostly $\frac{1}{2}$ -1 in. long, 1- $1\frac{1}{4}$ lines wide, spreading in flat sprays, or the upper lvs. and those on main st. of the branches often only 1-5 lines long and awl-shaped: cone oval, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long, $\frac{1}{2}$ - $\frac{3}{4}$ in. broad, maturing the first autumn; scales 14-26; seeds elliptic, narrowly margined, 2 lines long. Confined to northern and central Coast Ranges of Calif. on slopes exposed to sea influences. Gn. 76, p. 172. G.W. 13, p. 331; 14, p. 511.—Reproduces by seeds and by stump-sprouts, the latter numerous and remarkably persistent, often producing merchantable lumber. Var. *glauca*, Hort. Foliage with a decidedly bluish cast.

gigantea, DC. (*S. Wellingtonia*, Seem. *S. Washingtonia*, Sudw.). CALIFORNIA BIG TREE. Fig. 3612. Tree 150-325 ft. high, with trunk 10-30 ft. in diam.: crown pyramidal on young trees, rounded at summit or much broken in age: branches pendulous, cord-like: lvs. scale-like, $\frac{1}{8}$ - $\frac{1}{2}$ in. long, sharp-pointed, adherent to the st. which they thickly clothe, the tip free: cone ovoid, 2-3 $\frac{1}{4}$ in. long, 1 $\frac{1}{2}$ -2 in. broad, opening only slightly, maturing the second summer, persistent; scales 25-45; seeds oblong or somewhat ovate, wing-margined, 2 $\frac{1}{2}$ -3 lines long. Western slopes of Sierra Nevada. C. L. A. 7:364. G. C. III. 27:374; 34:401. G. F. 10:515 (adapted in Fig. 3612). R. H. 1913, p. 55. J. H. III. 67:348. G. W. 2, p. 195; 3, p. 77; 6, p. 397; 13, p. 331. —Reproduces in nature only by seeds. As usually grown the trunk is clothed to the ground with short slender up-curved branches, making a very ornamental tree, but in mature native specimens the trunk is clear of limbs up to 80-200 ft. Var. *péndula*, Hort. WEEPING BIG TREE. A form in which the branches are strongly recurved, closely covering the st. and producing a narrow cylindric effect similar to that of Italian cypress. Originated in Eu. and prop. by grafting upon normal *S. gigantea*. G. C. III. 31:388. R. H. 1906, p. 395. Var. *glauca*, Hort. Foliage bluish green; said to be of slow growth.

HARVEY MONROE HALL.

The sequoias.

The two great sequoias of California have a place of their own in science, history, and literature. Haenke, the botanist of the Malaspina expedition of 1791, first collected *S. sempervirens*, the coast redwood of California. Four years later Menzies, of the Vancouver expedition, secured specimens near Santa Cruz. Lambert published it in 1824 as *Taxodium sempervirens*. Douglas referred it to the same group, but in 1847 Endlicher created the separate genus *Sequoia*.

3611. *Sequoia sempervirens*. ($\times \frac{1}{2}$)

Two living sequoias, *S. sempervirens* and *S. gigantea*, are all that remain of many species that flourished in Tertiary times over a large part of the northern hemisphere. More than forty fossil species have been discovered, but there is still much confusion in regard to the botany of the extinct kinds. They have been found, however, from Italy north to Spitzbergen, and across northern Asia. Several now extinct species, such as *S. angustifolia*, *S. Heerii*, and *S. Langsdorffii*, grew in

California and Oregon in Miocene times. Asa Gray and others have told the story of the rise and fall of this great family of conifers, which was once as abundant as any tree-group in the world, but was cut off, swept away, destroyed by the glacial age, and survived only in parts of California. The *S. sempervirens* seems to be a descendant of the fossil *S. Langsdorffii*; *S. gigantea* appears related to the fossil *S. Sternbergii*. The famous petrified forest of Arizona was a species of *Sequoia*, according to the United States Geological Survey. These Arizonian giants which grew millions of years ago, went down under a permanent ocean, were covered with sandstone, and rose again with the present continent. In like manner vast periods of time lie between the present forests of sequoias and their ancient representatives. The value and interest of these wonderful trees are greatly increased by reason of their botanical and historical importance.

At the present time the coast redwood occupies only a narrow belt of country near the Pacific Ocean, nor is it continuous even there; the giant redwood, or California big tree, exists only in a few small and isolated groves, scattered over less than 60 square miles in all, extending along the western side of the Sierra Nevada range. Compared with the enormous territory once occupied by now extinct species of sequoia, the modern representatives of this ancient and honorable family are reduced to a very small area.

The first-known of the sequoias, and much the more valuable species, economically speaking, was *S. sempervirens*, the coast redwood of California. This is one of the most important timber trees of the world, and its forests, comparatively limited in area, have yielded and are still yielding, the most easily obtained, the most durable and profitable fencing and building lumber of the Pacific coast. The reproductive powers of the tree are enormous; no other known conifer so persistently sprouts from the stump, so rapidly makes new forests, or so well resists fire. But it does not thrive farther inland than the limits of the sea-fog, and a large part of the original area covered by this noble tree has been denuded by successive fires and destructive lumbering methods. Small redwood forests occur in Monterey County, but the most southern forests of commercial importance are in Santa Cruz. The belt, broken by the Bay of San Francisco, extends north through Marin, Sonoma, Mendocino, Humboldt, and Del Norte, and a few miles across into the southern borders of Oregon, which state contains about 400 acres of redwoods. The real redwood forests are all contained within a strip of coastlands 450 miles long and rarely more than 20 miles wide. The actual bodies of redwood within this region are merely a chain of isolated groups separated by clearings or by large areas on which redwoods never grew. A small grove, now practically destroyed, existed fifty years ago on the east side of the Bay of San Francisco, in Alameda County. Well-borers have found redwood logs in a perfect state of preservation in various parts of the Coast Range far south of where the trees now grow, even to Los Angeles and San Diego, showing that in some former period of greater rainfall and more sea-fog, redwood forests extended much farther down the coast.

The climate where the redwood thrives is comparatively equable, marked by fogs and cool summer winds from the southwest. The tree delights in rich sheltered mountain valleys and fertile slopes, in dripping fogs and in heavy winter rains. Going east from the ocean, in the redwood region, one suddenly comes to the top of a ridge, to overlook oaks and pines, and at once reaches the plainly marked edge of the *S. sempervirens* forest.

While *S. sempervirens* is sometimes called second in size among the giant conifers of the Pacific coast, the tallest tree yet authentically measured is 340 feet high, exceeding in height the tallest living tree of the Sierra

species, and it is probable that trees exist which rise to nearly 400 feet, and therefore deserve to take first place among the conifers. Many trees of 20 and even 22 feet in diameter at 5 feet from the ground, and from 300 to 325 feet in height, are still standing in the redwood forests. The finest groves of redwoods contain many specimens that range from 150 to 250 feet or more in height and have a diameter of 12 to 18 feet. In such forests the trunks rise in clear red-brown shafts to a height of 75 to 150 feet before they branch; they stand so close that the masses of timber that exist on each acre are greater than are found in any other known forest, and through their far-distant tops the sun seldom reaches the warm sheltered soil of the Coast Range cañons. With proper management, under the principles of scientific forestry, the redwood region as it exists today could be maintained, and its future yield greatly increased, but otherwise in forty or fifty years the commercial value of the entire area will be practically destroyed.

The annual output of the redwood forests of California has steadily increased in recent years until now (1916) it approximates 25,000,000 feet, board measure (The Pioneer Lumberman statistics). Stands of 250,000 feet, board measure, to the acre are not uncommon. One tree is on record as having yielded 480,000 feet of merchantable lumber.

Nearly all of the coast redwood is in private hands, but the state of California in 1901 appropriated \$250,000 to create a "redwood park" in the famous Big Basin of Santa Cruz County. Here, at the present time (1916) the state owns and cares for 3,800 acres, 1,500 of which are dense virgin forest, and much of the rest is thinly timbered. The possibilities of this superb and easily accessible park are very great. It was secured for the people by the efforts of many organizations and individuals, chief among which were the Sempervirens Club, and the late Professor Dudley of Stanford.

The Muir Grove of 295 acres is a fine forest in Redwood Cañon, Marin County, on the south side of Tamalpais, which was the gift of the Hon. William Kent to the nation. The Bohemian Club Grove on Russian River will probably remain uncut for generations. The beautiful Armstrong Woods in the same region have been offered to the state of California, but have not yet been purchased.

The *S. sempervirens*, even more than *S. gigantea*, is connected historically with many and great names. Not only Haenke, Menzies, and Douglas, but also Coulter and Hartweg aided in its introduction to Europe, where numerous horticultural varieties are in cultivation. *S. sempervirens* var. *adpressa*, Carr., is a smaller tree than the type form, with creamy white younger leaves and more glaucous older leaves. It is called in California the "white redwood" and the "silverleaf redwood." Other horticultural varieties in cultivation are known as *S. gracilis*, *S. taxifolia*, *S. picta*, *S. albo-spica*, and *S. glauca*. The golden forms found in many other conifers occasionally appear, but cannot yet be called fixed. No really dwarf redwood is yet extant. Larger-leaved or more compact forms can be selected from the forest, and the tree responds easily to selection and culture. It thrives in gardens in the Sacramento Valley, in the Sierra foothills, and in many parts of southern California, so that its range for ornamental uses can be greatly extended on the Pacific coast. It has been largely planted in Europe, particularly in English parks, and, as was to have been expected, does best in well-drained rich soil near the ocean but sheltered from cold winds.

The most famous of the sequoias and certainly the most widely known of all living conifers is the great redwood of the Sierras, *S. gigantea*. It is undoubtedly one of the rarest of all living species of trees and one of the most easily visited and studied. It is the best living representation in the whole world of a past geologic

age, and it is the most noble and impressive of trees. The interest attached to this sequoia is therefore distinctly international, and an immense body of literature has gathered about it.

Jepson, in his "Silva of California," 1910, lists thirty-one known groves of big trees in the California Sierras, containing 86,499 trees. While private owners control much of these areas, still a large part is in the National

3612. *Sequoia gigantea*.

Forests and Parks, where, under protection, the safety of the tree is assured and reproduction is excellent. In the Fresno grove, for example (Sierra National Forest), thousands of young trees are now growing. The low vitality of the seeds of *S. gigantea*, long a matter of complaint among nurserymen, appears to be less marked than formerly, and nearly all the groves show young trees.

The measurements of standing trees and the age-estimate made in the last decade have materially altered former conclusions. Sudworth has published an excellent table of measurements in the Calaveras Grove, and Jepson has supplemented them with measurements elsewhere. Sudworth measured thirty trees which were from 9 to 19½ feet in diameter 6 feet above the ground, and from 237 to 325 feet high. Former measurements were generally taken at the surface of the ground and hence were most misleading. A tree in Giant Forest, on the Kaweah, for example, measured (in circumference) at the surface of the ground 72 feet, but at 11 feet, where the bulge ceased, and the true shaft began, was but 57½ feet in circumference. The famous Boole tree, in Fresno County, girths 109½ feet at the surface, and 77 feet at 10 feet from the ground.

The problem of the age of the sequoias has long occupied the attention of students; popular literature has reveled in extravagant statements on this subject, so that many persons believe that trees now standing were in existence before the pyramids were built. As regards the coast redwood, so many trees have been cut and the rings counted that its age is now well known; this species lives from 400 to 1,300 years, or may possibly reach 1,500 years in a few cases. In respect to the Sierra redwoods, *S. gigantea*, the heavy logging done in recent years on private lands has enabled foresters to make careful age-determination. They find that mature trees range from 400 to 1,500 years. It remains to determine the resisting powers of mature trees. A few old fallen trees have been found whose rings showed ages of 2,200 to 2,300 years. John Muir estimated a partly burned tree at 4,000 years, but this is open to discussion.

The economic value of the coast redwood is so high that every principle of wise conservation requires more careful management of private forests, more complete reproduction and the reforestation of cut-over areas. Little attention has yet been paid to the by-products

from the present waste which technical chemists are able to make profitable. This is also true of the *S. gigantea* when lumbered on private lands; the beauty and durability of the timber, and the value of its possible by-products make care in reforesting eminently desirable. Pencil manufacturers are beginning to use the wood of selected trees of *S. gigantea*. The rapidity of growth of both sequoias when young, and when favorably situated, is so great that the forestry of the future is likely to extend rather than diminish these forests.

CHARLES HOWARD SHINN.

SERAPIAS (ancient name of an orchid, derived from Serapis, an Egyptian divinity). *Orchidaceæ*. Terrestrial herbs with the habit of *Orchis*: sepals connivent in the form of a helmet; petals included, small; labellum not spurred, with erect lateral lobes and a larger undivided, middle lobe; pollinia with a common viscid disk; rostellum laterally compressed.—Four or 5 species are known from the Medit. region. Keep the plants partially dry during winter months. Give plenty of water when in vigorous growth. Pot in leaf-mold, loam, and sand.

The above is the genus *Serapias* as formerly understood and known to horticulturists. With the recent use of this name for the *Cephalanthera-Epipactis* group, however, the following species are thrown in the genus *Serapiastrum*, taking the names *S. cordigerum*, A. A. Eaton, and *S. Lingua*, A. A. Eaton. See Vol. III, p. 1357.

Lingua, Linn. St. erect, up to 1 ft. high, bearing several narrow, acute lvs.: sepals lanceolate, greenish or purplish labellum much longer; lateral lobes rounded, erect middle lobe oblong-lanceolate, acuminate, smooth, red. Medit. region. B.M. 5868, B. G.C. III. 48:482.

cordigera, Linn. Resembles the preceding species in habit: labellum brownish red, middle lobe ovate, acuminate, subcordate at the base, pilose. Medit. region. B.M. 5868, A. R.H. 1892:390. G.C. II. 20:341.

S. Helleborine, Linn., of Eu. and very local in this country, is not a horticultural subject.

HEINRICH HASSELBRING.

L. H. B.†

SERENÒA (after Sereno Watson, distinguished American botanist, 1826-1892). Also written *Serenæa*. *Palmdææ*. Low shrubby or tree-like, more or less armed palms.

Caudex creeping, branched, clothed with the fibrous bases of the lf.-sheaths: lvs. terminal, orbicular, coriaceous, deeply plicate-multifid, glaucous beneath, with narrow bifid infolded segms.; rachis none; ligule short; petiole plano-convex, dentate on the margins: spadix long, tomentose, the flexuous rachis covered with deeply obliquely fissured, tubular sheaths, the spreading branches forked, the alternate branchlets very slender: spathes many, sheathing the peduncle: bractlets minute: fls. white: fr. ovoid, black, an inch long.—Species 2, Fla. to S. C. Cult. in the temperate house, or outdoors from Charleston southward.

The saw palmetto is the native creeping fan-leaved palm. Those who are clearing land in Florida consider it a nuisance. It is, however, of great interest to northern tourists, many of whom like to take home a small Florida palm in a pot or tub. This species does very well in pots, though it is of slow growth. Relatively speaking, it is very hardy, as it will stand a temperature of 10° F. The leaves of the saw palmetto, both fresh and dried, are sent north in great quantities for Christmas decoration. The "crowns" are also largely used for the same purpose and deserve a greater popularity. Crowns are whole tops cut off; they have no roots, and only a part of the stem. They give the effect of the whole plant and are therefore much more desirable for some purposes than single leaves. They will last for weeks, if kept moist, in the shade and free from drafts. Crowns 3 to 5 feet high are considerably used for large decorations. (E. N. Reasoner.)

serrulata, Hook. f. SAW PALMETTO. A shrub: st. creeping, branching, 4-8 ft. long: lvs. 2-4 ft., erect, circular in outline, fan-shaped, shorter than the slender, spiny-edged petiole; segms. slightly cleft at the apex, without thread-like filaments: spadix densely tomentose, shorter than the lvs.: drupe black, $\frac{2}{8}$ - $\frac{3}{4}$ in. long. Summer.

arborëscens, Sarg. Tree, 30-40 ft. high, with 1 or several erect or decumbent sts.: lvs. semi-orbicular, truncate at base, yellowish green above, bluish green below, 2 x 2 ft., divided nearly to the base into narrow linear-lanceolate lobes: spadix drooping, about 3 ft. long, the fls. yellow-green. S. Fla.—Differs from foregoing in arborescent habit, more elongated spadix, much smaller fls. and smaller, globose fr. and seeds.

N. TAYLOR.†

SERICOCÁRPUS (Greek, *silken fruit*). *Compositæ*. Five species of perennial herbs from N. E. U. S. closely allied to *Aster* and scarcely distinguishable from the section *Biotia* of that genus. The achenes are not so strongly compressed as in *Aster*. The fl.-heads have white rays and pale yellow disks which sometimes become purplish. They are erect perennials with alternate lvs. and medium-sized heads of white ray- and disk-fls. *S. rigidus*, Lindl., the only western representative of the group (Brit. Col. to Calif.) was once offered.

SERICÓGRAPHIS: *Jacobinia*.

SERÍSSA (from the Indian name). *Rubiaceæ*. Branched shrub, glabrous or the branches puberulent, fetid when bruised, adapted to the greenhouse: lvs. rather small, opposite, subsessile, ovate; stipules persistent: fls. rather small, axillary or terminal, solitary or fascicled, white; calyx-tube obconical, limb 4-6-parted, the lobes subulate-lanceolate; corolla funnel-form, tube and throat pilose inside, limb 4-6-lobed, short, the lobes obtusely 3-lobed; stamens 4-6; ovary 2-celled: fr. subglobose.—One species, S. E. Asia.

fétida, Lam. (*S. japonica*, Thunb.). About 2 ft. high: lvs. rather leathery, ovate, acuminate: fls. white. Japan. B.M. 361 (as *Lycium japonicum*). Var. **variegata**, Hort., has yellow-margined lvs. F. TRACY HUBBARD.

SERJÂNIA (named in honor of Paul Serjeant). *Sapindææ*. Climbing or twining shrubs adapted to the warmhouse, and grown in the open in warm countries: lvs. alternate, without stipules (or with minute stipules), ternate, twice-ternate or odd-pinnate, frequently pellucid-punctate: racemes or panicles axillary, frequently bearing 2 tendrils; fls. yellowish, irregular, polygamous; sepals 5 (or 4, 2 connate), imbricate, the outer ones smaller; petals 4, the fifth seat vacant; disk undulate, swollen into 4 glands, 2 larger and 2 smaller, sometimes obsolete; stamens 8; ovary 3-celled, sessile or short-stipitate: samara 3, indehiscent.—About 190 species, Trop. and Subtrop. S. Amer. Probably very little cult.

cuspidata, Cambess. (*Urvillea ferruginea*, Lindl.). Climbing: branches acutely triangular, the angles densely brown-pilose: lvs. ternate; lfts. somewhat cordate at base, generally ovate in outline, somewhat 3-lobed, irregularly and coarsely toothed, the terminal lft. somewhat decurrent on the petiole: fls. rather large for the genus; petals usually glabrous: fr. large, ovate, 3-winged. Brazil. B.R. 1077. Gt. 63, p. 325.

fuscifolia, Radlk. Tall climbing rufous-pubescent shrub with costate branches: lvs. biternate, the lfts. ovate or ovate-lanceolate, acute or somewhat obtuse, simply or double serrate, more or less rufous pubescent beneath and on the nerves above, minutely pellucid-punctate, the terminal one contracted into a petiole and the lateral ones sessile: fls. small, somewhat pedicellate, sepals tomentose: fr. ovate-elliptic, mostly puberulent or velutinous. Brazil.—Cult. in Calif.

F. TRACY HUBBARD.

SERRADELLA is an annual leguminous plant valuable as a fodder crop on dry and sandy sterile soils. See *Ornithopus*.

SERRÁTULA (from *serra*, alluding to the roughly toothed leaf-margins). *Compositæ*. A horticulturally unimportant group of composites consisting of about 30 species of herbaceous thistle-like perennials grown for their purple or violet fls.: sts. simple or branched: lvs. alternate, dentate, or much cut into sharp but usually unarmed segms., green both sides or sometimes pale and canescent beneath: infl. of a single pedunculate head or, as in the following, of a lax corymb; heads equal-fld., the involucre bracts in many series, narrowly acuminate at the apex, but not as in many thistles, spiny; fls. purple, but not very showy. Cult. in open border, but perhaps not in Amer. outside botanic garden collections. Eu., N. Afr., to China and Japan.

tinctória, Linn. A much-branched, freely flowering perennial, about 2-3 ft. tall: lvs. very variable, usually deeply pinnately cleft or divided and generally lanceolate in outline; the upper sometimes undivided and petioled, the basal usually divided and nearly sessile: fls. in a dense corymbiform infl. or thin, frequently sparse and lax, purple. Cent. Eu. July and Sept.

S. atriplicifolia, Benth. & Hook. Of vigorous growth: lvs. large, heart-shaped: heads globular, attaining height of 5 ft.: fls. purple. Cent. China.

N. TAYLOR.

SÉSAMUM (Greek name taken by Hippocrates from the Arabic). *Pedaliaceæ*. Herbs, erect or prostrate, scabrous or rarely glabrous, suitable for the warmhouse, and for the open in the S.: lowest lvs. opposite, the upper and almost all alternate, petioled, entire, incisedentate, 3-cleft or pedately cut: fls. pale or violet, solitary in the axils; calyx rather small, 5-parted; corolla-limb 2-lipped and 5-lobed; stamens 4, didynamous; ovary 2-celled: caps. oblong or ovoid.—About 20 species, Trop. and S. Afr., E. Asia. The only species of importance is *S. indicum*, which has been extensively cult. in the tropics from ancient times. The seeds are sold in Amer. under the name of bene. They yield about half their weight of oil-of-sesame (known also as benne-, gingili-, or teel-oil), which is odorless and does not easily become rancid. This oil is universally used in India for cooking and anointing. Large quantities of oil and seed are imported from India to Eu. for the manufacture of soap and adulteration of olive-oil. Also cult. in northern states as a medicinal herb, the mucilaginous lvs. being used in dysentery and diarrhea of children. The oil of sesamum, however, which is expressed from the seeds in large doses a laxative.

indicum, Linn. (*S. orientale*, Linn.). Plant 1-2 ft. high: lvs. variable, 3-5 in. long, oblong or lanceolate, the lower often 3-lobed or parted: corolla pale rose or white, 1 in. long, tubular, 5-cleft, the 2 lobes of the upper lip shorter. July. Tropics. B.M. 1688.—White- and black-seeded varieties have been known for at least two centuries. Runs wild in the extreme S. WILHELM MILLER.

SESBANIA (from *Sesban*, the Arabian name of *S. ægyptiaca*). Syns., *Daubenônia*, *Glottidium*. *Leguminosæ*. Herbs or shrubs, sometimes arborescent, but short-lived, suitable for the warm- and coolhouse, and for outdoor planting in the far South.

Leaves abruptly pinnate; lfts. many-paired, very entire; stipels minute or none: racemes axillary, lax; fls. yellow, red-purple, variegated, or white, slender-pedicelled; calyx broad, tube truncate, toothed or subequally lobed; standard orbiculate or ovate, spreading or reflex, wings falcate-oblong, keel incurved, obtuse or obtusely acuminate, with long claws; stamens free from the standard; ovary often stipitate: legume linear or rarely oblong, compressed, 4-angled or 4-winged.—About 30 species, widely distributed in the warmer regions of both hemispheres.

ægyptiaca, Poir. A much-branched, pale green, glabrous shrub, 5-10 ft. high: lvs. nearly sessile; lfts. 10-20 pairs, glabrous, glaucous, oblong-linear, blunt with a faint mucro: fls. bright yellow, standard round, emarginate, more or less clothed with purple: pod 6-8 in. long, distinctly torulose. July, Aug. Tropics of the Old World.—Often cult. in European gardens.

grandiflora, Poir. A short-lived, soft-wooded tree, 20-30 ft. high: lvs. 6-12 in. long; lfts. 41-61, linear-oblong, pale green, glaucous: fls. rose-red, white, or rusty red, 2-4, in short axillary racemes; standard oval-oblong: pod 1 ft. or more long, falcate, firm, not torulose. July, Aug. Mauritius, India to N. Austral. G.Z. 29, p. 170.

punicea, Benth. (*Daubenônia punicea*, DC.). Shrub or small tree, several feet high, somewhat glaucous and glabrous: lfts. commonly 8-9 pairs, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, narrowly oblong; stipules small: fls. 8-10 lines long, bright red-purple, in lax racemes; calyx truncate, teeth small; standard broadly rotundate: pod 2-4 in. long, thick, 4-angled, wings leathery, about 2 lines broad. Brazil.—Intro. into S. Calif.

Tripétii, Hort. (*Daubenônia Tripétii*, Poit. *D. Tripetiána*, Poit.). Shrub or small tree, about 6 ft. high: lvs. pinnately compound, dull green above, glaucescent beneath: fls. orange-red, rather large, in drooping racemes; standard scarlet, much paler on the inner face, with a yellow spot on the claw; wings and keel paler. Argentina.

F. TRACY HUBBARD.

SÉSELI (old Greek name for an umbelliferous plant). *Umbelliferae*. MEADOW SAXIFRAGE. Perennial and biennial herbs in the temperate and cold regions of the Old World, of perhaps 50-60 species, sometimes mentioned in horticultural literature as acceptable border plants. Erect and branched, with lvs. decompound or 2-3-pinnate, and compound umbels of small white fls., the involucres of few or many bracts or sometimes wanting; calyx-teeth either prominent or minute; petals notched; styles very short: fr. nearly terete, ovoid or oblong. *S. Libanotis*, Koch, of wide distribution in Eu., is perhaps most likely to appear as a cult. plant: perennial, 1-2 ft., erect and stout, glabrous or slightly pubescent: lvs. bipinnate, the lfts. ovate and sessile: umbel rounded, with many pubescent rays, and many-bracted involucres and involucrels.

SESÛVIUM (derivation unknown). *Aizoaceæ*. Erect or prostrate, branched, succulent herbs or subshrubs, adapted to the warm- or coolhouse: lvs. opposite, somewhat fleshy, linear or oblong: fls. axillary, sessile or pedunculate, solitary, clustered or rarely subcorymbose, frequently flesh-colored or purple, with 2 bracts or bractless; calyx-tube turbinate, the lobes 5, oblong, obtuse, colored inside; petals none; stamens 5; ovary free: caps. oblong, membranaceous, 3-5-celled, circumscissily dehiscent.—About 13 species, warmer temperate and tropical regions of the world, usually littoral. *S. Portulacástrum*, Linn. A diffuse procumbent or prostrate herb often wholly blood-red or purple: lvs. succulent, linear to oblanceolate or obovate-oblong, much narrowed at the base: fls. axillary, purplish or rose, peduncles equaling or shorter, rarely longer than the fls.; calyx deeply 5-lobed, the lobes ovate-lanceolate, obtuse with a mucro just below the apex behind; ovary usually 3-celled. Tropics and warmer regions of both hemispheres.—Sometimes used as a pot-herb.

SETÀRIA (Latin, *seta*, a bristle). *Gramineæ*. Annual or sometimes perennial grasses with bristly spike-like panicles: spikelets as in *Panicum*, but subtended by 1 to several bristles that extend beyond the spikelet and persist after the spikelet falls: the fr., that is, the mature fertile floret, usually transversely wrinkled.—Species about 40 in the warmer regions of the world.

Several species are annual weeds, such as YELLOW FOX-TAIL (*S. glauca*, Beauv.) with oblong yellow spikes, and 5 or more bristles below each spikelet, and GREEN FOX-TAIL (*S. viridis*, Beauv.), with somewhat pointed green spikes and 1-3 bristles below each spikelet. Many American botanists use the name *Chætochloa* instead of *Setaria*. (Dept. Agric., Div. Agrost., Bull. 21, is devoted to this genus.) The setarias are scarcely horticultural subjects, being primarily forage plants; but they are so widespread in cult. and the forms are so confused that a somewhat full discussion of them may be inserted here.

A. *Plant perennial.*

macrostachya, HBK. (*S. Alopecurus*, Fisch. *S. alopecuroides* var. *nigra*, of the trade). An erect or ascending perennial: spike slender, tapering at apex; bristles 1 or sometimes 2, $\frac{1}{2}$ -1 in. long; spikelets $\frac{1}{2}$ in. long; first glume one-third to one-half, second two-thirds to three-fourths as long as the equal sterile lemma and fr.; first glume inflated about the base of the spikelet. Texas to S. Amer.

AA. *Plants annual.*

magna, Griseb. A coarse stout native, resembling common millet: spike $\frac{1}{2}$ in. thick, as much as a foot long, tapering above and below; bristles 1-3, scarcely $\frac{1}{2}$ in. long; spikelets $\frac{1}{2}$ in. long, elliptical; first glume one-third as long as second glume and sterile lemma, equaling the spikelet; fertile lemma smooth. Marshes of Gulf States as far north as Md.

italica, Beauv. COMMON MILLET of the U. S. (but not of Eu., this being *Panicum miliaceum*); also called GERMAN MILLET and HUNGARIAN GRASS. Culm 3-5 ft. high: spike yellow or purple, compound, more or less glomerate; bristles 1-3, often shorter than the spikelet. Thought to have been derived from *S. viridis*. Gn. 12, p. 69.—The cult. of millet dates from prehistoric times. At present it is raised extensively in parts of Asia as a food-plant. In the U. S. millet is raised for fodder. The "Japanese millets" belong to *S. italica*, while the "Japanese barnyard millets" are *Echinochloa Crusgalli* or *E. frumentacea*.

The forms of *S. italica* may be distinguished from *S. viridis* by the articulation of the fruit (fertile floret), or what is commercially known as the seed. In the former species the fruit at maturity disarticulates above the glumes and falls away free from them. In *S. viridis* the fruit falls away surrounded by the glumes. The varieties of *S. italica* have been classified by Hubbard (Amer. Journ. Bot. 2:187.1915) as follows:

A. *Fr. yellowish to straw or light brown.* (Stramineo-fructa.)

B. *Bristles green.*

c. *Panicle more or less open-lobulate.*

Subsp. **stramineo-fructa**, Hubb. Bristles noticeably longer than spikelets: a large plant with heads 4-12 in. long, and as much as 2 in. wide, usually strongly lobed. This is one of the forms cult. as German millet. Forma **brevisetà**, Hubb. Bristles shorter than the spikelets or barely exceeding them. Cult. as Golden Wonder millet.

cc. *Panicle dense or slightly lobulate at base.*

Subvar. **germanica**, Hubb. Bristles noticeably longer than spikelets: head usually 2-3 in. long, $\frac{1}{4}$ - $\frac{1}{2}$ in. broad. One of the forms cult. as common millet.

BB. *Bristles purple.*

c. *Panicle more or less lobulate.*

Var. **Höstii**, Hubb. Head large, lobulate, purple. Cult. as German millet.

cc. *Panicle dense or slightly lobulate at base.*

Subvar. **Métzgeri**, Hubb. Bristles noticeably longer than spikelets. Cult. as common millet, a common

form. Sometimes called Hungarian grass, a name that should apply to var. *atra* (see below).

BBB. *Bristles brown.*

Var. **brunneoseta**, Hubb. Head large, lobulate, brown. Aino millet, occasionally cult. Subvar. **dénsior**, Hubb. Head compact, scarcely lobulate. Another form of Aino millet.

AA. *Fr. reddish or orange.* (Rubrofructa.)

Subsp. **rubrofructa**, Hubb. The form cult. in U. S. is var. **purpureoseta**, Hubb., with lobulate head and purple bristles. Turkestan millet. Subvar. **violacea**, Hubb., with dense head and purple bristles. Kursk millet. Siberian millet.

AAA. *Fr. blackish, brownish black or purplish black with pale yellowish straw lines intermingled, these sometimes predominating.* (Nigrofructa.)

Subsp. **nigrofructa**, Hubb. The common form cult. in U. S. is var. *atra* with small dense heads, 1-3 in. long, with purple-brown bristles. Commonly cult. as Hungarian grass.

Many other varieties are cult. in the Old World.

A. S. HITCHCOCK.

SEVERÍNIA (named for M. A. Severino, a Neapolitan). *Rutaceæ*, tribe *Citrææ*. Small woody plants distantly related to the orange.

Spiny shrubs or small trees with short and stiff branches: spines single, at one side of the bud in the axils of the lvs.: lvs. simple, conspicuously veined, borne on short apterous petioles: fls. 5-merous, occurring 2 or 3 together in the axils of the lvs.; petals small, white; stamens 10, free; ovary 2-celled, with 1 ovule in each cell: fr. a small nearly globular berry, black when mature.—Only one species is known, usually called *Atalantia buxifolia*, native to S. China and Formosa. See Swingle, in Journ. Wash. Acad. Sci., Vol. 6, No. 19. 1916.

buxifolia, Ten. (*Citrus buxifolia*, Poir. *Limnoria bilocularis*, Roxbg. *Sclerostylis buxifolia*, Benth. *Atalantia buxifolia*, Oliver). A spiny shrub or dwarf tree native to S. China, intro. into cult. in Eu. late in the 18th or early in the 19th century and often considered by botanists to belong to the genus *Atalantia*, from which it differs widely in the character of the fr. which is a black berry, the ovary walls becoming succulent as the fr. ripens: lvs. simple, obovate-oblong, very obtuse or emarginate, $1\frac{1}{2}$ in. long, having numerous fine veins; spines solitary: fls. axillary, in fascicles or solitary, small, subsessile; stamens 10, free: fr. a true berry, becoming more or less fleshy at maturity, turning black, 2 (or sometimes 3) -celled, each cell containing a single seed, cells not filled with gum or pulp vesicles; seedlings with subterranean cotyledons, first lvs. very small, spirally arranged. Ill. Seemann, Bot. Voy. Herald, pl. 81; Penzig, Studi bot. sugli agrumi, Atl., pl. 11, figs. 6-17; Swingle in Journ. Wash. Acad. Sci., Vol. 6, No. 19. 1916.—This plant, which has lvs. resembling the box (*Buxus sempervirens*) is common in S. China and Hongkong, and occurs also in Formosa. It is grown in botanic gardens and Eu. and has been intro. in this country. It is erroneously listed by some nursery firms as *Triphasia monophylla*. It is sometimes used as a hedge-plant in La. and other Gulf states, and is well adapted for this purpose, as it does not grow to large size and has very spiny forms that can be prop. from cuttings. It is being tested by the Dept. Agric. as a stock for the cult. citrus frs., as it is able to thrive in soils too salty to permit Citrus to grow.

WALTER T. SWINGLE.

SEYMERIA (named in honor of Henry Seymer, an English naturalist). *Scrophulariaceæ*. Erect branched annual or perennial, mostly hardy herbs, used for bedding on account of their fls.: lvs. mostly opposite, incised-dentate or dissected, the uppermost floral ones reduced

to entire bracts: fls. in interrupted racemes or spicate, the pedicels solitary and without bracts, yellow; calyx campanulate, with 5 narrow, entire or denticulate lobes; corolla-tube short and broad, rarely exserted, the throat broad, 5-lobed, the lobes broad or oblong, spreading; stamens, 4, subequal: caps. globose at base, the apex frequently compressed, acuminate or beaked.—Ten species, 9 from N. Amer., Texas-Mex. region and 1 from Madagascar. Seeds are sown in a well-drained bed of rather light rich soil. *S. pectinata*, Pursh. About 1 ft. high, minutely viscid-pubescent or glabrate: lvs. pinnately parted into rather few short- or oblong-linear divisions or the upper incisely few-toothed or entire: calyx-lobes linear; corolla hairy outside. N. C. to Fla. and Ala., perhaps to Texas. *S. tenuifolia*, Pursh. About 2-4 ft. high, very slender: lvs. copiously 1-2-pinnately parted: fls. on filiform pedicels; calyx-lobes setaceous; corolla very deeply cleft, the lobes oblong. N. C. to Fla. and Texas.

SHAD-BUSH: *Amelanchier*.

SHADDOCK. A name used in the West Indies and Florida for the forms of the pummelo, *Citrus grandis*, supposed to have been introduced from India into the West Indies sometime in the seventeenth century by a Captain Shaddock.

The shaddocks are large usually pear-shaped fruits with a thick peel and have a firm pulp of rather poor flavor. The leaves have very broad, winged petioles and the twigs are usually more or less hairy, especially when young. Shaddocks were formerly grown in Florida but have been superseded by the grapefruit (see page 1391, Vol. III) as the latter finds more favor in American markets. Pummelos, very like shaddocks, are still grown in India, China, and the East generally. See *Pummelo* (page 2857, Vol. V).

WALTER T. SWINGLE.

SHAGBARK: *Hickory*.

SHALLOT is *Allium ascalonicum*, Linn., native of Syria. It is grown chiefly for the small oblong-pointed gray bulbs (into which the parent bulb separates after harvesting in summer), which are used in cookery for flavoring; the leaves are sometimes eaten in a green state. The bulbs are of mild flavor. Shallots are little known in North America. They are grown as are garlics (see *Garlic*), the bulbs or cloves being separated and planted early in spring in any good garden soil. Each bulb produces several, all cohering by the base. The mature bulbs are 2 inches or less long and only about half that in diameter. The leaves are small, terete, and hollow. The plant is hardy. The bulbs will keep several months or even a year. Small onions are sometimes sold as shallots.

L. H. B.

SHAMROCK. Half the world is sure that shamrock is the wood-sorrel, *Oxalis Acetosella*. The other half is equally certain that the true shamrock is white clover, *Trifolium repens*. In the time of Spenser's "Faerie Queene," shamrock was said to be good to eat. This applies to the former plant, but not to the latter. Moreover, according to Sowerby, the wood-sorrel is in perfection on Saint Patrick's Day, while white clover is not. The wood-sorrel is sent in great quantities from Ireland to London for Saint Patrick's Day. On the other hand, it is said that clover is the plant most commonly used in Ireland. Half a dozen other plants have their followers, and these are all plants with three leaflets. Nevertheless there are those who deny that Saint Patrick used the shamrock as a symbol of the trinity. These declare that the water-cress is the true shamrock. The question will always remain an open one. See Dyer's "Folk-Lore of Plants."

WILHELM MILLER.

SHAMROCK, INDIAN: A name found in some English books for the *Trillium*. *S. Pea:* *Parochetus communis*.

SHEPHERDIA (named for John Shepherd, an English botanist). *Elæagnaceæ*. Shrubs, or small trees with scurfy scales, two of which are in cultivation, one for its striking appearance, the second for its edible fruit.

Leaves opposite, petiolate, oblong and entire: fls. small, dioecious, in very short spikes or racemes, opposite to small bracts along the rachis, male spikes many-fld., female 2-fld. in the axils of lvs. or often sessile at leafless nodes; calyx of male fls. 4-parted, of female fls. urn-shaped, 4-cleft; stamens in male fl. 8, alternating with 8 lobes of a thick disk; ovary becoming a nut or achene and invested by the fleshy calyx, forming a drupe-like fr.—Three species, N. Amer. The genus *Shepherdia* was founded by Nuttall in 1818. Rafinesque's *Lepargyræa*, 1817, is equivalent, and the species have been placed under this name; it is not accepted under the International Rules. In *S. argentea*, the buffalo berry, the fr. is edible when made into jellies and conserves, and is much prized in the upper plains region for household uses.

The shepherdias are hardy plants, withstanding extremes of cold and drought. They are of easy culture, and grow readily from stratified seeds. For ornamental planting, they are prized for bold positions in front of shrubby masses, where their gray or white colors afford excellent contrasts. *S. canadensis* is particularly well adapted for planting on dry rocky sterile banks, where most bushes find great difficulty in securing a foothold. *S. argentea* succeeds better in the upper Mississippi Valley than in the eastern states. Staminate and pistillate plants of it have different forms of buds.

A. Lvs. green above.

canadensis, Nutt. (*Lepargyræa canadensis*, Greene). Spreading twiggy bush 3-6 or even 8 ft. tall, the young branches brown-scurfy: lvs. ovate, oval, or elliptic, rather thick, green above but rusty beneath: fls. yellowish, in short clusters at the nodes: fr. small ($\frac{1}{4}$ in. or less long), oval, red or yellow, insipid. Along streams and on lake-banks, Newfoundland to Brit. Col. and in the northern tier of states, and southward in the mountains to Utah.—The yellow-fruited form has been distinguished as *f. xanthocarpa*, Rehd.

AA. Lvs. silvery above.

argentea, Nutt. (*L. argentea*, Greene). **BUFFALO BERRY.** Fig. 680, Vol. I. Upright shrub, or sometimes almost tree-form, reaching 18 ft. tall, thorny, the young growth silvery tomentose: lvs. oblong, cuneate-oblong or oblong-lanceolate, silvery on both sides: fls. yellowish, in dense small fascicles at the nodes: fr. globular or ovoid, about $\frac{1}{4}$ in. long, red or yellow, acid, edible. Kans. to Minn., west and north. See *Buffalo Berry*.

S. rotundifolia, Parry, from Utah, is a silvery tomentose and scurfy evergreen bush: lvs. round-oval or ovate, mostly somewhat cordate, short-petioled: fls. stalked in the axils of the lvs., the staminate mostly in 3's and the pistillate solitary: fr. globular, scurfy, ripening in July.

L. H. B.

SHERWOODIA: *Shortia*.

SHÓRTIA (named for Dr. Charles W. Short, a botanist of Kentucky). *Diapensiaceæ*. Two acaulescent herbs, with the habit of galax.

Rootstocks creeping: lvs. evergreen, round-cordate: fl. solitary on a slender leafless scape, the calyx with scaly bracts, the corolla bell-shaped and obtusely 5-lobed; stamens 5, the filaments adnate to the corolla, alternating with 5 scale-like staminodia; pistil 3-angled and 3-loculed; style filiform and stigma 3-lobed: fr. a globular caps. From this, *Schizocodon* is distinguished by linear-elongated staminodia and fringed corolla. Allied genera mentioned in this Cyclopædia are *Galax*, *Pyxidanthra*, and *Schizocodon*. *Diapensia* has two alpine and boreal species, one in the Himalayas and the other in N. Eu. and N. Amer. *Berneuxia*, the remaining genus, has a single species in Thibet, not in the American trade. *Shortia californica* of seedsmen

will be found under *Actinolepis*. Of the little family Diapensiaceæ, with its 6 genera and 9 species, *Shortia galacifolia* is historically the most interesting. Michaux collected the plant in 1788 in the high mountains of Carolina, but as his specimen was in fr. rather than in fl., Richard, the author of Michaux's *Flora Boreali-Americana*, did not describe it. Asa Gray examined Michaux's specimen, preserved in Paris, in 1839, and afterward founded the genus *Shortia* on it. Great search was made for the plant in the mountains of Carolina, but it was not rediscovered until 1877. The history of the efforts to find the plant is one of the most interesting chapters in American botany. For historical sketch, see Sargent, Garden and Forest, vol. 1, p. 506 (1888). Torrey & Gray founded the genus *Shortia* in 1842. In 1843, Siebold & Zuccarini founded the genus *Schizocodon*, from Japan. To this genus Maximowicz added a second Japanese species, *S. uniflorus*; the fls. of this plant, as of *Shortia*, were unknown when the plant was first recognized. It transpires, however, that *S. uniflorus* is really a *Shortia*, thus adding another instance to the growing list of bitypic genera that are endemic to Japan and E. N. Amer.

Shortia, like most plants considered rare, is really not so rare as local, though the few stations where it is

3613. *Shortia galacifolia*. (×½)

found abundantly do not seem to present special conditions not to be found elsewhere, and it is hardly understood why it should, in common with certain other plants, have remained strictly local, in an indigenous state. For the successful culture of *Shortia*, humus and leaf-mold seem to be absolutely required, and it should either be planted where these conditions are natural or else be constantly supplied with this food. This suggestion, if carried out with many plants, such as galax, pyrola, chimaphila, and probably *Epigæa repens*, will ensure success, where if ordinary garden treatment only is given the entire disappearance of the plants may be expected in a season or two. Semi-double and pink-flowering plants are not rarely found, and it seems likely that cultivation may bring out several worthy varieties. In England *Shortia* is often grown successfully as a pot-plant, and is far more appreciated than in America. It is difficult to procure seed, as the flowering-stem usually withers away before maturing, though *Shortia* is readily propagated by division and runners. It is a shade-loving plant and is a choice addition to the ericaceous bed, where it will thrive under rhododendrons and kalmias. (Harlan P. Kelsey.)

galacifolia, Torr. & Gray (*Sherwoodia galacifolia*, House). Fig. 3613. Lvs. all radical, long-petioled, the blades orbicular or broadly ovate-orbicular, often slightly cordate, at the apex obtuse or even retuse, the margin repand-serrate; peduncles slender, 3-8 in. tall,

1-fl., bracted near the top; fl. inclined or nodding, white, 1 in. across, the obtuse lobes undulate. Mountains of N. C. B.M. 7082. G.C. II. 15:596; III. 5:397; 17:453. G. 34:521; 36:121; 37:309. Gn. 38:204; 67, p. 285; 71, p. 7; 73, p. 189. J.H. III. 30:299; 58:373. G.M. 34:353. G.F. 1:509 (adapted in Fig. 3613). Gn.W. 7:605; 20:295. A.G. 12:287. Mn. 6, p. 83. C.L.A. 17:414. F.S.R. 3:8.—A very attractive plant with the look of a pyrola; very local. Var. *rosea*, Hort., has rose-colored fls.

uniflora, Maxim. (*Sherwoodia uniflora*, House). Very like *S. galacifolia*: lvs. cordate, broader than long and deeper toothed,—sinuate-toothed in *S. uniflora* and only repand-toothed in *S. galacifolia*. Japan. B.M. 8166. G.C. III. 31:337; 43:220, 221. G. 36:803. Gn. 67, p. 192; 71, p. 310; 72, p. 202. F.S.R. 3, p. 247.—Offered by importers of Japanese plants, but little known horticulturally. Var. *grandiflora*, Hort., has larger fls. than the type, being as much as 1½ in. across. G. 32:253. Gn. 74, p. 164; 78, p. 177. G.M. 53:205. L. H. B.

SHRUBBERY: Planting, Vol. V.

SHÛRIA: Scheeria.

SIBBÁLDIA (named for Robert Sibbald, Scotch naturalist). *Rosaceæ*. Low and depressed perennials, hardy and rare in cult., sometimes used in alpine-gardening: lvs. 3-foliolate, alternate; stipules prominent: fls. cymose, yellow, small; calyx flattish, 5-cleft and with 5 bractlets; petals 5, linear-oblong, minute; stamens 5, alternate with the petals: achenes 5-10.—About 5 species, natives of the colder parts of the North Temperate Zone. Reduced by Bentham and Hooker to a section of *Potentilla*, but separated by most authorities.

procumbens, Linn. Lfts. 3, wedge-shaped, 3-toothed at the apex: petals yellow. Ranges from the arctic regions to the summits of the White Mts. and in the Rockies comes as far south as Utah. It is also found in arctic and alpine Eu. and Asia. B.B. 2:217.—This plant is recommended by some persons, but is not known to be advertised for sale in Amer.

F. TRACY HUBBARD.†

SIBIRÆA (named for the habitat of the plant, Siberia). *Rosaceæ*, subfam. *Spirææ*. Two shrubs from N. E. Asia and W. China closely allied to *Spiræa*, but differing in the narrow entire lvs., the polygamodioecious fls. disposed in paniced racemes and in the 2-seeded carpels connate at the base. *S. lævigata* is a deciduous upright shrub with rather stout branches, with alternate, entire, generally oblong lvs. and with small short-stalked white fls. in spike-like racemes crowded into terminal panicles. It possesses no particular ornamental qualities and is rarely cult.: hardy N. The hardness of the recently intro. *S. tomentosa* has not been sufficiently tested. Prop. is by seeds sown in spring or by layers. *S. lævigata*, Maxim. (*S. altaïensis*, Schneid. *Spiræa lævigata*, Linn.). Shrub, 5 ft. high, with stout upright branches: lvs. cuneate-oblong, bluish green, glabrous, 1½-3½ in. long: fls. polygamous, greenish white, in terminal panicles, 3-5 in. long, those of the staminate plant somewhat showier. May. Siberia. G.O.H. 89. Var. *angustata*, Rehd. Lvs. narrow-lanceolate, 1-4 in. long and rarely more than ½ in. broad: infl. pubescent, W. China. Var. *croatica*, Schneid., from S. E. Eu., is similar to the preceding variety, but the lvs. are obtuse and the infl. not pubescent. It is not yet intro. *S. tomentosa*, Diels. Low shrub, to 2 ft.: lvs. oblong-obovate to oblanceolate, acutish and mucronulate, with silky silvery white tomentum beneath while young, glabrous above, 2-3 in. long: fls. greenish yellow in dense panicles about 2 in. long. S. W. China.

ALFRED REHDER.

SIBTHORPIA (named in honor of John Sibthorp, 1758–1796). *Scrophulariaceæ*. Hardy or greenhouse perennial herbs, often rooting at the nodes, grown mostly for the flowers.

Leaves alternate or fascicled, petioled, orbiculate-reniform, coarse-crenate or incise-pinnatifid; pedicels axillary, solitary or fascicled; fls. yellow, yellowish rose or red; calyx campanulate, 4–8-cleft, the lobes slightly unequal; corolla-tube short or very short, rotate, limb spreading; anthers sagittate; caps. membranaceous, compressed, loculicidally dehiscent, the valves splitting to the middle.—About 7 species, E. Eu., Trop. and N. Afr., mountains of India and S. Amer.

europæa, Linn. A hardy trailing perennial with very slender sts.: lvs. orbicular, less than $\frac{1}{2}$ in. across, 7–9-lobed: fls. small, on rather short pedicels, the 2 upper lobes of the corolla yellowish, the 3 lower pink. Deep woods, Eu. Var. *variegata*, Hort., a form with bright golden green foliage, is cult. abroad.

peregrina, Linn. Tender trailing greenhouse perennial: lvs. much crenated; peduncles frequently fascicled, 2 in. long: fls. yellow, 5–8-parted; stamens slightly shorter than the corolla. June. Mauritius. B.M. 218 (as *Disandra prostrata*). F. TRACY HUBBARD.

SICANA (Peruvian name). *Cucurbitaceæ*. Annual slender subglabrous tall-climbing vines, used out-of-doors in the S. for ornament: lvs. palmately 5–9-lobed, very glabrous and shiny; tendrils 3–5-cleft, the branches adhering at the tip: fls. rather large, yellow, monœcious, all solitary; calyx-tube short-campanulate, 5-lobed, the lobes ovate-lanceolate, recurved; corolla inflated-campanulate, 5-lobed above the middle, the lobes broad-ovate; stamens 3 in the male fl.: fr. large, fleshy, many-seeded, fragrant and edible.—Three species, Trop. Amer. Allied to *Cucurbita*, but differing in having wide-spreading or reflexed calyx-lobes and the anthers not united.

odorifera, Naudin, the CURUBA and PEPINO ANGOLO of the tropics, has been intro. in the U. S. as the CASABANANA. Fig. 3614. It is a very quick-growing and interesting ornamental vine: plant glabrous, the sts. angled: lvs. large (often 1 ft. across), nearly orbicular in outline, deeply cordate at the base, strongly about 5-lobed and the lobes repand-toothed or angled: fls. solitary, monœcious, the corolla small and yellowish, urn-shaped, with small reflexed lobes; stigmas 3, each 2-lobed: fr. like a slender vegetable marrow, 1–2 ft. long, smooth, nearly cylindrical, orange-crimson, with a very strong aromatic odor. R.H. 1890:516.—Probably native to Brazil, but occurring also in Mex. and the W. Indies. The curuba seems to be grown in the tropics as an ornamental plant, although it is said to afford edible preserves. The plant climbs 30–50 ft. It is well worth growing on summer arbors, or under glass if one has room for it. The frs. are very interesting, fragrant, and ornamental. Perennial.

S. atropurpurea, André. Has shorter subpyriform, brilliant violet-purple frs., and purple-tinted under surfaces of the lvs. Perhaps a form of *S. odorifera*. Uruguay. R.H. 1894:108.—*S. spherica*, Hook. f. Fls. large and spreading, more like those of *Cucurbita*: lvs. reniform, 3–5-lobed: fr. globose, size of a small orange. Jamaica. B.M. 7109.

L. H. B.

SÍCYOS (Greek name for the cucumber). *Cucurbitaceæ*. Climbing or prostrate annual herbs useful for ornamental purposes, one especially for covering walls and the like: lvs. membranaceous, angulate or lobed, rarely deeply 3–5-lobed; tendrils 3-cleft: fls. small or minute, whitish, monœcious, the sterile and fertile mostly from the same axis, the former corymbd, the latter in a capitate cluster, long-peduncled; petals 5, united below into a bell-shaped or flattish corolla; ovary 1-celled: fr. ovoid, dry, and indehiscent, 1-seeded.—About 50 species, warmer parts of N. and S. Amer., Pacific islands, and Austral.

angulatus, Linn. BUR CUCUMBER. Annual climbing herb: lvs. very broadly rhombic-ovate, more or less shallow, 5-angled or lobed, palmately veined; the lobes rather broad-deltoid, the midlobe abruptly and narrowly acuminate, the lateral lobes apiculate, base somewhat halberd-shaped with a rounded rather narrow sinus; the petiole slender and glandular-pilose. S. Maine and W. Que. to Fla. and west to Minn., E. Kans., and Texas.—Used on account of its rapid growth for screening walls, lattice-work, and the like.

SIDA (from the old Greek name for *Nymphæa alba*; given without explanation by Linnæus). *Malvaceæ*. Herbs or shrubs with the indumentum frequently soft or tomentose, adapted to the warm- or coolhouse or some of them hardy; one species, *S. rhombifolia*, now cultivated in India for its fiber.

Leaves simple or lobed, usually serrate or dentate: fls. sessile or pedunculate, solitary or glomerate, axillary or in terminal racemose spikes or heads, various colored and sometimes showy, often small, yellow or whitish; calyx 5-toothed or 5-cleft; staminal column divided at the top into numerous filaments: carpels 5 or more, when ripe separating from the axis, generally 2-awned at the summit; seed 1 to a carpel and pendulous.—About 120 species, widely distributed in Afr., Asia, Austral., and N. and S. Amer.

3614. *Sicana odorifera*, the cassabanana. ($\times \frac{1}{4}$)

A. Lf.-blades palmately lobed: fls. white.

hermaphrodita, Rusby (*S. Napæa*, Cav. *Napæa hermaphrodita*, Linn.). A hardy herbaceous perennial 5–8 ft. high, from a stout root: lvs. 3–8 in. long, 3–7-lobed; lobes triangular, long-acuminate, irregularly serrate: fls. perfect, white, about 1 in. across, in terminal corymbose panicles. June–Aug. S. Pa., W. Va., and Va. B.B. 2:422.—Cult. same as for hollyhocks; prop. by seed. Index Kewensis refers the above species to *Napæa dioica*, Linn., but according to Gray's Synoptical Flora of North America the two species belong to separate genera, the fls. of the first being hermaphrodite, of the second dioecious. *Napæa dioica* is a strong-growing perennial 5–9 ft. high, with large radical lvs. often 1 ft. across and 9–11-cleft, the segms. cut into lanceolate serrate lobes: fls. dioecious, white, smaller than in *Sida Napæa*. For pictures of the two plants, see B.B. 2:420, 422.

AA. Lf.-blades merely toothed: fls. of various colors.

B. Lvs. ovate to cuneate or lanceolate.

rhombifolia, Linn. Shrubby or subshrubby: lvs. very variable, rhomboid-lanceolate to lanceolate, lower surface usually paler or even hoary: fls. axillary, solitary, pale yellow, rarely white, the petals blotched with red at the base. Tropics and subtropics of both hemispheres.—Yields a good fiber, and its cult. for this purpose has recently been encouraged in India. Probably of little value for ornament.

BB. *Lvs. linear or linear-oblong.*

Élliottii, Torr. & Gray. A hardy perennial herb, slender, 1-3 ft. high, with lvs. 1 in. long and yellow fls. Sandy soil in the southern coast states. Offered by western collectors in 1881. B.B. (ed. 2) 2:520.

F. TRACY HUBBARD.†

SIDÁLCEA (compound of *Sida* and *Alcea*, related genera). *Malvaceæ*. Some of the sidalceas are annuals, but those in cultivation are hardy perennials, being recommended for the herbaceous border.

Leaves palmately cleft or parted, stipular: fls. often showy, pink, purple, or white, in terminal racemes or spikes, mostly without bracts or involucels beneath; stamens united into groups in a double series; carpels 5-9, reniform, separating at maturity.—About 30 species, natives of W. N. Amer. For monograph, see Gray, *Syn. Fl. N. Amer.*, vol. 1, p. 302. Of easy cult. Prop. by seeds or division.

A. Fls. white, with bluish anthers.

cándida, Gray. Fig. 3615 (adapted from Pacific R. R. Report). Plant erect, from more or less creeping root-stocks, the sts. somewhat branched above, 2-3 ft. tall, glabrous or nearly so: radical lvs. nearly orbicular, cordate, obtusely lobed or deeply crenate; st. lvs. 5-7-parted, the divisions narrow and often notched: fls. 1 in. or more across, white, in an erect spike-like raceme. Rocky Mts. Gn. 24, p. 396; 28, p. 29. G.M. 49:316. Gn.W. 24:299 (as *S. malvæflora*). J.H. III. 56:451. R.H. 1891, p. 356.

3615. *Sidalcea candida*. (×½)

AA. Fls. normally colored (rarely white forms).

B. Mature carpels smooth (not reticulated).

spicàta, Greene (*S. Murrayana*, Hort.). One or 2 ft. tall, sparingly branched or simple, often more or less hirsute: upper lvs. parted into linear and often lobed divisions: fls. rather small, purplish, in an oblong, more or less interrupted spike, the pedicels short or almost none. Calif., Nev., and Ore.

BB. Mature carpels conspicuously reticulated.

malvæflòra, Gray. Sts. erect or ascending, 1-6 ft. or even more, sparingly hirsute: lvs. green, small, incised-crenate, the upper ones 5-cleft or 5-divided, segms. nar-

row and entire or broader and pinnate-lobed: fls. 2 in. or less across when fully expanded, purple. Calif. H.U. 2, p. 65 (as *Nuttallia malvæflora*). Var. **atropurpùrea**, Hort. (*S. atropurpùrea*, Hort.), grows 2-3 ft. high, with large, open, purple fls. Var. **Listeri**, Hort. (*S. Listeri*, Hort.), known also as "pink beauty," has satiny pink fls. It is of European origin.

neo-mexicàna, Gray. One to 8 ft. high: sts. hirsute-pubescent, more or less branched: radical lvs. orbicular, 5-9-lobed or incisedly crenate; cauline lvs. parted, segms. 3-lobed: raceme many-fl'd.: fls. rose; calyx hirsute: carpels smooth and glabrous. Mountains of New Mex. and Ariz. northward to Wyo.

campèstris, Greene. Two to 5 ft., often branching above, glabrous or sparingly hirsute-pubescent: lvs. green, the lower ones rounded and variously lobed, the upper ones 5-7-parted into narrow divisions: fls. about 1½ in. across, in strict spike-like racemes, purplish, the petals often lacinate. N. Calif. to Brit. Col.

oregàna, Gray. Less hairy than *S. campestris*, the racemes becoming branched and paniculate: fls. smaller. Ore. and Wash.

The following are offered in the trade, but unknown botanically: *S. mariana*, Hort., growing 3 ft. high: fls. bright pink.—*S. mexicana*, Hort., a strong grower, 3 ft. high, with satiny rose fls. borne on wiry sts.

F. TRACY HUBBARD.†

SIDERÏTIS (Greek, *iron*; the plants were supposed to have a healing power for wounds caused by iron. Dioscorides also used the name for other plants credited with the same ability). *Labiatæ*. Herbs, subshrubs, or shrubs frequently lanate or softly pilose, mostly hardy or half-hardy but some of them coolhouse plants: lvs. entire or toothed, the floral ones reduced to bracts or similar to the lower cauline: fls. in axillary clusters of 6 to many fls. or in interrupted or dense spikes, small, often yellowish; calyx tubular, 5-10-nerved, with 5 erect somewhat spiny teeth, or rarely muticous; corolla-tube included, bare or with a pilose ring inside, the limb 2-lipped, the posterior somewhat flat, entire, emarginate or 2-cleft, the anterior spreading, 3-cleft; stamens 4, didynamous: nutlets ovoid, smooth, obtuse, not truncate at the top.—About 60 species, Medit. region, Canary Isls., and the Orient. Probably the commonest is *S. scordoides*, Linn., a hardy subshrub, about 1 ft. high, with ovate, oblong, or oblong-linear, incised-toothed lvs., spikes which are 1-3 in. long of yellowish fls. with the upper lip of the corolla paler or white. S. Eu. Variable.

Other species which have been mentioned are: *S. canariensis*, Linn. A greenhouse shrub several feet high, with ovate, crenate lvs. which are cordate at the base, and subglobose whorls of 20-30 fls. Canary Isls.—*S. cándicans*, Ait. A greenhouse shrub about 3 ft. high, covered with white wool, with ovate lvs. which are truncately cordate at the base, whorls of about 10 subsessile fls., the lower ones distant. Madeira and Canary Isls.—*S. incana*, Linn. A half-hardy subshrub about 1 ft. high, with white-woolly branches, sessile, oblong-linear, obtuse, white-woolly lvs. and distant whorls of about 6 fls. Spain.—*S. perfoliàta*, Linn. A half-hardy subshrub about 1-1½ ft. high, with half-clasping, ovate-oblong or lanceolate softly villous lvs. and distant whorls of sessile fls. S. Eu.—*S. taurica*, Willd., is a half-hardy shrub about 1½ ft. high with thick oblong-lanceolate or spatulate lvs., the lower ones crenulate, densely white-woolly. Caucasus region and Asia Minor.

F. TRACY HUBBARD.

SIDEROXYLON (Greek, *iron* and *wood*, referring to the hardness of the wood). *Sapotaceæ*. Trees and shrubs, with simple lvs. and small fls. in axillary clusters: fls. 5-merous or rarely 6-merous; calyx-lobes roundish or ovate, usually obtuse, nearly equal; corolla more or less bell-shaped; stamens attached to the tube at the base of the lobes and opposite to them; staminodia scale-like or petaloid; ovary usually 5-loculed: berry ovoid or globose.—About 110 species, mainly tropical, a few extra-tropical. S. Afr., Austral., and New Zeal.

Mastichodéndron, Jacq. Tree, to about 50 ft., with somewhat variable lvs. usually oval or ovate-oblong, 2-8

in. long, and small yellow fls.: fr. about $\frac{3}{4}$ in. through. W. Indies; cult. in S. Calif.—Said to yield a sort of chewing-gum. Wood useful in furniture-making.

F. W. BARCLAY.

SIEVEKINGIA (named for Dr. Sieveking). *Orchidaceæ*. Pseudobulbous orchids suitable for the warm-house; of secondary importance.

Pseudobulbs usually clustered, 1-lvd.: lf. usually petioled: labellum immobile, angled with the column, ventricose, either simple or tridentate at the apex.—About 3 species, natives of Cent. and S. Amer. Allied to *Lacæna*.

Reichenbachiana, Hook. f. Pseudobulbs clustered, 1 in. long, ovoid or obpyriform, blotched with blood-red when old: lf. single, 4-5 in. long, petioled, elliptic-lanceolate, acuminate at both ends, dark green, strongly 5-ribbed: fls. about 6 in a pendulous corymb, about $1\frac{1}{4}$ in. across; sepals subequal, ovate, pale straw-colored; petals linear, acute, golden yellow, they and the lip margined with long flexuous golden hairs; lip spread out, side lobes large, dimidiate-ovate, subfalcate, golden yellow, blotched with blood-red, midlobe small, linear, lacerate. Ecuador. B.M. 7576.

suavis, Reichb. f. Pseudobulbs pyriform, approximate: lf. petioled, cuneate-oblong, acute, plicate: fls. about 3 in a pendulous raceme; sepals greenish yellow, ovate; petals and lip deep yellow, the latter with a few minute blackish dots inside and some larger ones on the basal crest. Costa Rica.

There is a third species in the trade, *S. peruviana*, Rolfe, but while mentioned in *Orchid Review* it seems never to have been described. A native of Peru.

F. TRACY HUBBARD.

SIGMATÓGYNE (Greek *S* and *female*, referring to the S-shaped gynostemium, the peculiar column of the orchids). *Orchidaceæ*. Epiphytic herbs with perennial 2-lvd., small pseudobulbs: lvs. perennial, membranaceous: scape various-fld.(?), rising below the pseudobulb, 1-fld.: fls. perfect, small, diaphanous; perianth spreading, upside down, withering; sepals 3, free, the dorsal keeled, the lateral almost straight forward and symmetrical; petals 2, rather similar to the sepals; labellum free, inserted at the base of the S-bent rather broad gynostemium, somewhat mobile; column broad, thick, much shorter than the labellum; pollinia 4, in pairs; rostellum (beak) little bent down: caps. unknown. Two species, Himalayas. *S. Panilungii*, Pfitz. Plant small: scape scarcely exceeding the narrowly ovate pseudobulbs: sepals scarcely $\frac{1}{2}$ in. long, oblong, the dorsal carinate, acute, the lateral concave at base; petals similar, narrower; labellum entire, oblong, slightly dilated toward the apex. Assam.—The color of the fl. is not described and the scape including the fl. is only about $1\frac{1}{4}$ in. long.

F. TRACY HUBBARD.

SIGMATÓSTALIX (Greek *S* and *stake*). *Orchidaceæ*. Low herbs with very short, few-lvd. sts., covered with distichous sheaths and terminated by a 1-lvd. pseudobulb, suitable for the warmhouse: fls. in racemes, short-pedicelled, pendulous, medium-sized or small; sepals free, about equal, spreading, acute or acuminate; petals similar to the sepals only narrower; labellum long-clawed, 2-keeled; column elongated, very narrow; pollinia 2: caps. ovoid, 3-edged, beakless.—About 12 species, Trop. Amer. *S. bicornuta*, Rolfe. Cespitose, about 2 in. high: pseudobulbs elliptic-oblong, apex 1-lvd., base 4-lvd.: lvs. linear, subobtusate or minutely denticulate: scapes lateral, slender, few-fld.: fls. small, yellow with deep purple-red stripes; sepals linear-lanceolate, reflexed; petals linear-lanceolate, with 2 fleshy conical horns; labellum sessile, somewhat spreading, reniform-orbicular. Peru. *S. Elia*, Rolfe. Pseudobulbs compressed, ovate-oblong, apex 1-lvd., base 2-3-lvd.: lvs. oblong and very short bidentate, base attenuate: scapes slender, many-fld.: fls. yellow, spotted with red-

dish brown; sepals and petals oblong-lanceolate, acute, reflexed; labellum spreading, broad-clawed, 3-lobed, midlobe reniform-orbicular, lateral lobes reflexed, linear-oblong. Colombia. *S. peruviana*, Rolfe. Cespitose, about 2-3 in. high: pseudobulb ovoid or ovoid-oblong, apex 1-lvd., base 4-lvd.: lvs. linear, subobtusate, or minutely denticulate, base conduplicate: scapes lateral, slender, few-fld.: sepals and petals straw-colored with purple band at base of dorsal sepal and the petals, lip light yellow with a shiny orange-yellow crest; sepals oblong spreading; petals suberect, oblong; labellum sessile, deltoid-reniform, undulate. Peru.

F. TRACY HUBBARD.

SILÈNE (Greek name of one of Bacchus' companions described as covered with foam, also connected with *sialon*, saliva; referring to the stickiness of the stem and calyx of some species). Including *Heliospërma* and *Melandrium* in part. *Caryophyllaceæ*. **CATCHFLY**. **CAMPION**. Erect, cespitose, decumbent or diffusely climbing annual, biennial, or perennial herbs, some of them tender and grown in the greenhouse, others hardy and planted outdoors for their ornamental effect; often excellent plants for the rock-garden.

Leaves opposite, entire: fls. solitary or variously cymose, white, through pink to rose and purple; calyx 5-toothed, 10- to many-nerved, naked at the base; petals mostly crowned with a scale at the base of the blade; stamens 10; styles 3, rarely 4: pod 1-celled, sometimes 3-celled.—Over 400 species described, widely scattered over the world. There is a monograph of *Silene*, with a key, in the *Journal of the Linnean Society*, vol. 32 (1896), by F. N. Williams, with 390 good species. Williams refers the common *S. virginica* and *S. pennsylvanica* as well as the European *S. viscosa* to the genus *Melandrium*, characterized by a strictly unicellular caps. with no trace of septation at the base. Only a few of the known species are in cult.

Silenes are of easy culture. They mostly bloom in summer, and a few continue well into autumn. By good management the season of bloom may be continued through spring and summer. Toward this end the seeds of the common annual kinds should be sown in early autumn, instead of spring. As a rule, the common kinds prefer a sandy loam and full sunlight, but the rock-garden kinds require special treatment, and other suggestions for cultivation are given after the specific descriptions. The most popular kinds are the pink and rose annuals, *S. Armeria* and *S. pendula*. Of the perennials the most popular among the white-fld. kinds are *S. maritima* and *S. alpestris*, while *S. virginica*, *S. pennsylvanica* and *S. Schafta* are amongst the most popular kinds with colored flowers. A good horticultural review of the kinds in cultivation is found in *The Garden*, vol. 11, pp. 10-13 (1877).

KEY TO THE SPECIES.

- A. Duration annual or biennial.
- B. Plants glabrous, although viscid above in No. 1.
- C. All except the lowest lvs. ovate or ovate-lanceolate from a subcordate, clasping base. 1. *Armeria*
- CC. All except the lowest lvs. oblong or oblong-lanceolate from a connate base. 2. *compacta*
- BB. Plants pubescent or tomentose.
- C. Sts. simple. 3. *viscosa*
- CC. Sts. dichotomously branched, at least above.
- D. Fls. sessile, white. 4. *dichotoma*
- DD. Fls. pedicelled, finally pendulous, usually flesh-colored to purple but white in one variety. 5. *pendula*
- AA. Duration perennial.
- B. Height 1 ft. or more (Nos. 8, 12, 17, and 18 are usually less than 1 ft.; No. 9 is placed here with uncertainty as its height is not definitely stated).
- C. Nerves of the calyx 20.
- D. Sts. erect: base of lvs. cordate. . . 6. *fimbriata*
- DD. Sts. procumbent or ascending: base of lvs. narrowed.
- E. Fls. several to a st.: sts. ascending. 7. *latifolia*
- EE. Fls. 1 or few to a st.: sts. procumbent. 8. *maritima*
- CC. Nerves of the calyx 10.
- D. Plants glabrous.
- E. Lvs. linear-oblong. 9. *tatarica*
- EE. Lvs. lanceolate-spatulate. 10. *Asterias*
- DD. Plants pubescent or at least puberulent or pruinose-scabrous.
- E. The lvs. in whorls of 4 (the uppermost and lowest sometimes opposite). 11. *stellata*
- EE. The lvs. not in whorls of 4.
- F. Blades linear or narrowly lanceolate or oblanceolate.
- G. Sts. more or less decumbent or geniculate at the base.
- H. Fls. solitary on the peduncles. 12. *multicaulis*
- HH. Fls. mostly in 3-fld. cymes.
- I. Calyx oblong or obovate: fls. white or pink. 13. *Douglasii*
- II. Calyx long-cylindrical, pink, green-nerved: fls. bright carmine. 14. *laciniata*
- GG. Sts. erect.
- H. Fls. erect. 15. *Fortunei*
- HH. Fls. nodding. 16. *Scouleri*
- FF. Blades broader, usually ovate or obovate, sometimes broadly lanceolate or oblanceolate.
- G. Sts. more or less decumbent or procumbent.
- H. Infl. leafy and borne in the forks of the branches. 17. *Menziesii*
- HH. Infl. not leafy, usually at least partly terminal.
- I. Petals obcordate: fls. rose. 18. *rosiflora*
- II. Petals 4-cleft or 4-lobed: fls. scarlet. 19. *californica*
- GG. Sts. erect, usually stout.
- H. Fls. crimson or scarlet.
- I. Lvs. thin, spatulate or oblanceolate; apex blunt or abruptly acute. 20. *virginica*
- II. Lvs. thick, ovate-lanceolate; apex acute or acuminate. 21. *regia*
- HH. Fls. white, greenish white, or bright green.
- I. The fls. erect: lvs. tomentose. 22. *gigantea*
- II. The fls. nodding: lvs. pubescent but not tomentose.
- J. Base of calyx gradually attenuate to the pedicel. 23. *viridiflora*
- JJ. Base of calyx truncate and umbilicate. 24. *mellifera*
- BB. Height 2-10 in. (Nos. 8, 12, and 18 occasionally reach 1 ft.; No. 17 is often 1 ft. or more high; No. 9 may belong here but is probably taller than 1 ft.).
- C. Nerves of the calyx 20.
- D. Plant not caespitose. 25. *Zawadskii*
- DD. Plant caespitose.
- E. Lvs. linear: plant dwarf, 2-4 in. high. 26. *pumilio*
- EE. Lvs. lanceolate or ovate-lanceolate: plant 8-16 in. high. 8. *maritima*
- CC. Nerves of the calyx 10.
- D. Blades linear or narrowly lanceolate (the lowest lvs. of No. 30 are somewhat spatulate, the others linear).
- E. Species strictly glabrous.
- F. Peduncles 5-11-fld. 27. *Lerchenfeldii*
- FF. Peduncles 1-, rarely 2-fld.
- G. Sts. lacking or almost so: plants not more than 2 in. high. 28. *acaulis*
- GG. Sts. present: plants 4-6 in. high. 29. *dianthifolia*
- EE. Species more or less pubescent or at least viscid above.
- F. Petals 4-lobed.
- G. Fls. solitary or in 3's. 30. *quadrifida*
- GG. Fls. in panicles.
- H. Color of fls. white. 31. *alpestris*
- HH. Color of fls. cardinal-red. 14. *laciniata* var. *Purpusii*
- FF. Petals 2-lobed or 2-cleft.
- G. Calyx glabrous.
- H. Claws of the petals dilated and glabrous; calyx-teeth alternately oblong, obtuse and lanceolate, acute. 12. *multicaulis*
- HH. Claws of the petals ciliate; calyx-teeth ovate, obtuse. 32. *Saxifraga*
- GG. Calyx pubescent.
- H. Tube of calyx campanulate. 33. *odontopetala*
- HH. Tube of calyx clavate or tubular becoming oval.
- I. Fls. rose. 34. *Elizabethae*
- II. Fls. white.
- J. Infl. cymose, few-fld. 5. *ciliata*
- JJ. Infl. racemose-paniculate.
- K. Fls. erect. 36. *repens*
- KK. Fls. nodding. 37. *Reichenbachii*
- DD. Blades broader, when lanceolate, relatively broad as compared with the length.
- E. Plant glabrous. 38. *rupestris*
- EE. Plant pubescent or at least velvety.
- F. Lvs. lanceolate, oblong-lanceolate, or ovate-lanceolate, blade broadest at or below the middle.
- G. Fls. white.
- H. Infl. leafy, borne in the forks of the branches. 17. *Menziesii*
- HH. Infl. terminal on a st. ascending from below the rosette. 39. *caucasica*

- GG. Fls. rose or rose-purple. 18. *rosiflora*
 FF. Lvs. obovate or more or less spatulate, at least the lower, blade broadest above the middle.
 G. Claw of petal ciliate.
 H. Petals bifid. 40. *vallesia*
 HH. Petals 4-cleft. 41. *Hookeri*
 GG. Claw of petal glabrous.
 H. Apex of petal 4-toothed. 42. *pusilla*
 HH. Apex of petal 2-lobed or notched.
 I. Calyx long-cylindrical: fls. 1-5, axillary and terminal, solitary. 43. *Schafta*
 II. Calyx clavate: fls. in small dense terminal cymes. 44. *pennsylvanica*

1. *Arméria*, Linn. SWEET WILLIAM CATCHFLY. Fig. 3616. Annual, glabrous, viscid above: sts. 1-1½ ft. high, erect, simple or slightly branched: lowest lvs. spatulate, the others ovate or ovate-lanceolate, from a subcordate, clasping base: fls. pink or rose, in dense cymes, corymb-like, often dichotomous; calyx 10-nerved, cylindrical, clavate in fr.; petals obovate-cuneate, subretuse: caps. oblong. July-Sept. S. Eu. B.B. (ed. 2) 2:66. Var. *álba*, Hort., is a white-fl. form.

2. *compácta*, Fisch. Biennial, glabrous, glaucescent: sts. about 1½ ft. high, stout, simple or slightly short-branched above: lowest lvs. spatulate-lanceolate, the others oblong or oblong-lanceolate from a connate base: fls. pink, crowded in dense, sessile heads, with the uppermost lvs. involucrate; calyx clavate; petals obovate, entire: caps. oblong. July. E. Eu., Asia Minor. L.B.C. 17:1638.—Most of the material cult. under this name is *S. pendula* var. *compacta*.

3. *viscôsa*, Pers. Biennial, somewhat tomentose, very viscid: sts. stout, leafy, simple: lvs. somewhat undulate, radical oblong; cauline lanceolate, acute: fls. white, in short-peduncled, opposite cymelets, forming a long verticillate raceme; calyx very viscid, long-cylindrical, 10-nerved, in fr. clavate; petals deeply 2-parted into obovate-oblong segms.: caps. oblong. June, July. Eu., N. Asia. Var. *plena*, Hort., is said to grow 1 ft. high and to have bright rose double fls.—Use basal cuttings.

4. *dichôtoma*, Ehrh. Annual or biennial, minutely pubescent: sts. strictly dichotomous: lower lvs. spatulate, the others lanceolate, acuminate: peduncles very short, racemes in pairs, many-fl.: fls. white, sessile; calyx 10-nerved, the nerves green, more or less hirsute, oblong-cylindrical; petals 2-parted to the middle or more, the segms. obovate-oblong: caps. oblong. Eu., also intro. in N. Amer. and extensively escaped. B.B. (ed. 2) 2:67.

5. *péndula*, Linn. (*S. græca*, Hort., not Boiss. *S. ròsea*, Hort.). Fig. 3617. Annual, crisp-pubescent: sts. 6-10 in. high, decumbent at base, dichotomously branched above: lvs. oblong-spatulate to lanceolate;

floral lvs. oblong-lanceolate: fls. flesh-colored or rosy, in lax racemes, finally pendulous; calyx hirsute, reddish. 10-nerved, somewhat inflated after anthesis; petals large, obovate or 2-parted: caps. ovate. May-Aug. Medit. region. B.M. 114.—A variable species whose varieties seem to be nomenclatorially in confusion as the same form appears to bear several names; some of the forms offered in the trade are:

Var. *álba*, Hort., is a white-fl. form.
 Var. *Bónnettii*, Hort. (*S. Bónnettii*, Hort.), has brownish red sts. and lvs.: fls. shiny purple-red or dark purple.
 Var. *cárnea*, Hort., is a flesh-colored form of which there is a double variant known in the trade as *cárnea plena*.
 Var. *compácta*, Hort., is probably a compact-growing strain rather than a true variety; occurring in several color variations and both single and double.

G.C. III. 43:345; 55:174. Gt. 49, p. 555. G.Z. 18:32. A good bedding plant. Var. *lilácina*, Hort., is a form with rather lilac-purple fls. Var. *rubérrima*, Hort., Vilm., is a form with brownish red branches and bright rose or carmine fls. (R.H. 1884, p. 113); there is also a variation of this known in the trade as *rubérrima Bónnettii*, with reddish purple sts. and lvs. and rose-red fls., probably the same as var. *Bónnettii*.

6. *fimbriáta*, Sims. Perennial, about 2 ft. high, pubescent: sts. erect, leafy and sometimes branched from the axils: lvs. large, ovate, base more or less cordate, margin undulate; the upper lvs. lanceolate, all dark green: infl. a dichotomous panicle: fls. white; calyx whitish, inflated, ovate-campanulate, teeth short-triangular; petals cuneate at base, obovate above, deeply many-cut and fringed. Caucasus. B.M. 908.

7. *latifolia*, Brit. & Rendle (*Cucubálus latifolius*, Mill. *S. Cucubálus*, Wibel. *S. inflàta*, Sm. *S. venôsa*, Aschers. *S. vulgàris*, Garcke. *S. Zawádsckii*, Hort., not Herbach). BLADDER CAMPION. BLADDER CATCHFLY. COWBELL. WHITE BEN. Perennial, 1-3 ft. high, glaucescent, usually glabrous: sts. ascending: lvs. elliptical or lanceolate, acuminate, base narrowed: fls. polygamous-dioecious, numerous, white or pinkish, drooping, in corymbose cymes or panicles; calyx campanulate to subglobose, 20-nerved, glabrous, strongly inflated; petals narrow, 2-cleft: caps. ovate-globose. Eu., N. Afr., Asia, and naturalized in N. Amer. B.B. (ed. 2) 2:64.—The young shoots are said to be eaten by the poor folk of England as a substitute for asparagus; they taste something like green peas.

8. *marítima*, With. Perennial, caespitose, gray-green, 8-16 in. high: sts. numerous, the barren shoots procumbent, the flowering ascending: lvs. lanceolate or ovate-lanceolate, margin cartilaginous or crenate: fls. white, 1 or few to a st., but numerous, paniculate; calyx 20-nerved, inflated after anthesis; petals somewhat cleft and with 2 small scales at the base. June-Aug. Eu., N. Afr. Gn. 57, p. 372. G.M. 52:273.—The seaside form is said to be more glaucous than the mountain form. Allied to *S. latifolia*, but fewer- and larger-fl. Var. *plena*, Hort. (*S. marítima* var. *flòre-*

3617. *Silene pendula*. (×¼)

3616. *Silene Armeria*. (×½)

pleno, Hort.), grows 4–10 in. high and has fewer fls. than the type, but they are much larger, extremely double and remain in bloom longer. Niven says, "This variety makes a lovely rock-plant, and ought always to be placed in such a position that its stems, borne down by the weight of blossoms, may hang over the ledge of a rock; otherwise, if planted in a border, they get besprinkled with soil after every shower of rain." Niven adds that this variety produces no seed and is more easily prop. by cuttings than by division. Gn. 11, p. 12; 57, p. 126. R.H. 1906, p. 181. Var. *rôsea*, Niven, grows about 6 in. high and is said to have a less rambling habit and rose-colored fls. Origin unknown. This desirable form seems unknown in Amer.

9. *tatârca*, Pers. Perennial, glabrous: sts. geniculate, approximate, densely leafy: lvs. linear-oblong, attenuate toward the base, margin serrulate, glabrous: fls.

3618. *Silene virginica*. ($\times \frac{1}{2}$)

in second racemose panicles; peduncles opposite, 1–3 fld.; calyx subclavate, obscurely 10-striate, glabrous; petals 2-cut, the segms. oblong-linear, obtuse: caps. elliptical. E. Eu., W. Asia.

10. *Astêrias*, Griseb.; also misspelled *Asteris*. Perennial, glabrous, 3–4 ft. high: sts. tall, simple, rather viscid: lvs. lanceolate-spatulate, 4–5 in. long, obtuse, base attenuate; the uppermost oblong, elliptic-lanceolate: fls. purple, subsessile, in a many-fld., capitate cyme; calyx membranaceous, reddish, obconic-cylindrical; petals oblong, entire: caps. oblong. Macedonia and Roumania. Var. *grandiflora*, Hort., is about 3 ft. high and has the crimson-scarlet fls. in globose heads. Balkan Mts.

11. *stellata*, Ait. STARRY CAMPION. Perennial, 2–3 ft. high: sts. erect, branched, pubescent: lvs. in whorls of 4 (the uppermost and lowest sometimes opposite), ovate-lanceolate, acuminate, 2–3 in. long: fls. white, nodding, in an open panicle; calyx campanulate, pubescent, inflated; petals laciniately cleft, unappendaged.

Woods, Mass. to Neb., south to Ga. and Texas. B.M. 1107 (as *Cucubalus stellatus*). B.B. (ed. 2) 2:63.

12. *multicaulis*, Guss. (*S. Waldsternii*, Griseb. *S. Kitaibëlii*, Vis.). Perennial, 1 ft. or less high: caudices prostrate: sts. ascending, pruinose-scarious below, viscid above: lvs. linear-lanceolate, acute: fls. solitary on the peduncles, greenish white; calyx pale, glabrous, cylindric-clavate, base strongly attenuate; petals linear-cuneate, 2-cut: caps. oblong. S. Eu.

13. *Doúglasii*, Hook. Perennial, 1 ft. or more high, finely pubescent, scarcely viscid: sts. very slender, decumbent and geniculate at base: lvs. remote, long, linear to narrowly lanceolate-linear, 2–3 in. long: fls. white or pink, borne mostly in 3-fld., long-peduncled cymes; calyx oblong or obovate, rather narrow at base; petals 2-lobed, appendaged. June–Sept. Utah to Cent. Calif. north to Mont. and Brit. Col.—A variable species. Var. *Macounii*, Rob. (*S. Lyallii*, Wats.), is minutely pubescent: lvs. tapering gradually from near apex to base: calyx oblong, teeth purple-tipped. Wash. and Brit. Col., summits of the Rocky and Selkirk Mts.

14. *laciniata*, Cav. Perennial, $1\frac{1}{2}$ –3 ft. high: sts. pubescent, decumbent and erect-branched: lvs. large, lanceolate to narrowly linear, acute, attenuate at base, subsessile: fls. axillary and terminal, paniculate, somewhat nodding, bright carmine, about 1 in. across; calyx long-cylindrical, pink with 10 green nerves, slightly inflated after anthesis; petals 4-cleft to about their middle, lobes acute. Mex. B.R. 1444. P.M. 1:267. Var. *Purpusii*, Hort., is a dwarf, spreading plant, 6–8 in. high: lvs. narrow, green, somewhat woolly: fls. rich cardinal-red. Mex.

15. *Fórtunei*, Vis. Perennial, $1\frac{1}{2}$ –3 ft. high, woody at base, scaberulous-pubescent: sts. numerous, erect: lvs. linear-lanceolate, acute, attenuate to a ciliate petiole: fls. racemose with short cymose or approximate single-fld. branches, rose or white; calyx elongate-tubular, glabrous, strie netted above, teeth ovate, broad white-margined; petals with 2-aucricled claws, blade 2-parted, the lobes more or less deeply incised: caps. oblong. China. B.M. 7649. Var. *nana*, Hort., a dwarfier form with more deeply colored fls. Var. *rôsea*, Hort., has more brilliant pink fls. than the type.

16. *Scoûleri*, Hook. Perennial, $1\frac{1}{2}$ –2½ ft. high, pubescent, glandular-viscid above: root stout: sts. simple, erect: lvs. narrowly oblanceolate or lanceolate-linear, acuminate: fls. white or purplish, verticillately spicate or the lower ones in short appressed cymes; calyx clavate, nerves definite, teeth membranous and ciliate margined; petals auricled-clawed, bifid. Mountains of Ore., Idaho, and Mont., northward to Vancouver Isl.

17. *Ménziesii*, Hook. Perennial, 6 in. to 1 ft. or more high, finely glandular-pubescent: sts. weak, leafy, dichotomously branched above: lvs. ovate-lanceolate, acuminate at both ends, thin: fls. white, very small for the genus, borne in the forks of the branches and forming a leafy infl.; calyx obconical, obovate, or oblong, 2½–4 lines long; petals 2-cleft, commonly appendaged: caps. small. Mo. and Neb. to Assiniboia, westward and southward to Vancouver Isl., S. Calif. and New Mex. B.B. (ed. 2) 2:68.

18. *rosiflora*, F. K. Ward. Perennial, 6–12 in. high, branched: sts. suberect or procumbent, densely pubescent: lvs. scarcely petioled, up to 1 in. long, lanceolate, base slightly attenuate, apex acute, sparsely puberulous above, densely so beneath, margin ciliate: infl. terminal, laxly dichotomously cymose-corymbose: fls. rose; calyx tubular, 10-nerved, purple-saturated, densely glandular-pubescent; petals about ¾ in. long, clawed, blade broadly obovate.

19. *californica*, Durand. Perennial, 1–4 ft. high, hirtellous-pubescent: root vertical, simple, 2–3 ft. long: sts. procumbent or suberect, leafy: lvs. lanceolate or

ovate-elliptic, more or less narrowed at base, acuminate, rarely obtusish: fls. scarlet, large, 1 in. or more across, scattered; calyx funnelform-clavate; petals 4-lobed, commonly with 2 broad ones flanked by 2 narrower ones: caps. ovoid, concealed until dehiscence by the rather broad calyx. Coast Range, Ore. to N. and Cent. Calif.—Doubtful whether in cult.

20. *virginica*, Linn. FIRE PINK. Fig. 3618. Perennial, 1–2 ft. high, viscid-pubescent: sts. striate, single, simple: lvs. spatulate or oblanceolate, the lower narrowed to ciliate-fringed petioles, the upper sessile: fls. very large, 1 in. or more across, crimson or scarlet, loosely cymose, commonly nodding or reflexed after anthesis; calyx clavate or oblong; petals broadly lanceolate, 2 (rarely 4) -toothed at the apex. Open woods and rocky hills, N. Y. to Minn., south to Ga. and Ark. B.M. 3342. Gn. 22, p. 375. G. 8:417. B.B. (ed. 2) 2:64.

21. *regia*, Sims (*S. Bérgeri*, Hort., not Schott). ROYAL CATCHFLY. Perennial, 3–4½ ft. high: st. erect, stout, slightly viscid and rough-pubescent: lvs. sessile all but the lowest, thick, ovate-lanceolate, acute, 2–3 in. long: fls. numerous, deep scarlet, in a narrow cymose panicle, about 1 in. across; calyx oblong-tubular; petals emarginate or lacinate, crowned. July. Ohio to Ala., Tenn., and Mo. B.M. 1724. B.B. (ed. 2) 2:65.

22. *gigantæa*, Linn. Perennial, 3–4 ft. high: st. tall, stout, 4-angled below, viscid-pubescent: lvs. tomentose, the radical densely rosulate, thick, obovate, mucronate; the floral lvs. minute, linear-lanceolate: panicle long, raceme-like, with the cymes densely many-fld., remotely whorled and the uppermost sessile: fls. white; calyx hairy, obconical, 10-nerved; petals 2-parted into oblong segms.: caps. large, ovate. E. Medit. region.

23. *viridiflora*, Linn. Perennial, 1–2 ft. high: sts. simple or branched above, soft-pubescent, very viscid above: lvs. petioled, ovate-oblong, acute: fls. greenish white, in loose, elongated panicles, few, nodding; calyx glandular, reticulately green-nerved, narrowly cylindrical; petals deeply 2-cut into linear segms.: caps. oblong. S. Eu.

24. *mellifera*, Boiss. & Reut. Perennial, caespitose, 1½–2½ ft. high: sts. erect, stout, very short-puberulent below, very viscid above: lvs. acute, pubescent, the lower and rosette lvs. oval or spatulate-lanceolate, attenuate to a long petiole; the upper lanceolate or linear: fls. small, bright green, in long lax cymose panicles; calyx umbilicous, clavate, green-striate; petals clawed, the limb deeply 2-lobed, cuneate: caps. ovate-conical. Spain, Portugal, and Algeria.

25. *Zawádsckii*, Herbach. Perennial, 4–8 in. high: sts. rather erect, hirtellous-pubescent, densely villous above: lvs. rosulate, lanceolate, acuminate, narrowed to the ciliate base, densely punctulate-ciliate; cauline lvs. few, linear-lanceolate: fls. white, in a few-fld. raceme; calyx broadly ovate-campanulate, densely pubescent; petals bifid: caps. ovate. Austria.

26. *pumilio*, Wulf. Dwarf perennial: sts. a few inches high, caespitose, glabrous: lvs. linear, obtuse, ciliate: fls. solitary, rose, 1½ in. across, on slender pedicels; calyx faintly 20-nerved, oblong-campanulate, pubescent, somewhat inflated after anthesis, green or violaceous green; petals undivided or notched: caps. ovate-cylindrical. June. Austrian Alps.—A rare and choice plant. Niven says it has hard woody roots which are easily damaged in transit, and therefore those who wish the species should secure seeds.

27. *Lerchenfeldiana*, Baumg. Low caespitose perennial, glabrous and glaucous: sts. decumbent ascending: lvs. rosulate below, long-lanceolate, acute, attenuate at base; cauline lvs. oblong: fls. 5–11, in terminal corymbose cymes, rose; the peduncles short; calyx glabrous, hyaline-membranaceous, cylindrical-clavate; petals narrow-elongate, linear, retuse: caps. ovate. S. E. Eu.

28. *acaulis*, Linn. CUSHION PINK. MOSS CAMPION. Fig. 3619. Moss-like tufted perennial, about 2 in. high, glabrous: sts. almost lacking: lvs. clustered at the end of the much-branched rootstock, green, short, linear-subulate: peduncles 1-fld.: fls. reddish purple, ½ in. across; calyx campanulate, 10-nerved, glabrous; petals slightly notched, obovate, with a small scale at the base: caps. long-cylindrical or oval. May–Aug. Eu. L.B.C. 6:568. Gn. 75, p. 285; 76, p. 614. B.B. (ed. 2) 2:63.—According to Niven, this species is readily increased by division or by seeds, which it produces sparingly. The fls. have a tendency to become dicecious. Var. *álba*, Hort., forms dense cushions and has snow-white fls. somewhat smaller than the type. Var. *aurea*, Hort., has golden foliage and bright rose fls. Var. *exscäpa*, Koch (*S. exscäpa*, All.), has dense bright green cushions and paler pink (according to the trade sometimes white) fls. Var. *grandiflora*, Hort., forms moss-like tufts with crimson fls. June, July. Var. *plena*, Hort. (*S. acaulis* var. *flöre-plena*, Hort.), has dense cushions of light green foliage and double bright rose fls.

29. *dianthifolia*, J. Gay. Perennial, densely caespitose, 4–6 in. high, glabrous: sts. erect, 1 (rarely 2) -fld.: lvs. ciliate at the broadened base, narrowly linear, acute, the lower congested, the upper shorter; calyx reddish nerved, short obconic-cylindrical, teeth ovate; petals 2-parted above the middle into linear-oblong segms.: caps. ovate. Asia Minor.

30. *quadrifida*, Linn. (*S. quadridentata*, Pers.). Perennial, 2½–4 in. high, rather glabrous, caespitose many-stemmed: sts. slender, rather viscid, dichotomous: lower lvs. spatulate; the others linear: fls. solitary or in 3's; peduncles long and capillary, white; calyx oblong-turbinate; petal glabrous-clawed, blade obovate-spatulate, obtusely 4-lobed: caps. globose. S. Eu.

31. *alpéstris*, Jacq. Perennial, 4–6 in. high, caespitose, more or less viscid above: sts. dichotomous: lvs. mostly radical, lanceolate-linear, rather obtuse: fls. white, rather large, shining, in corymbose panicles; calyx

3619. *Silene acaulis*. (×½)

short, campanulate-clavate, not inflated, 10-nerved; petals obovate, 4-lobed at the apex, and with 2 teeth at the base of each petal. May–Aug. Mountains of E. Eu. Gn. 63, p. 231.—It forms a dense mass of underground sts. and is easily prop. by division or seeds. Var. *grandiflora*, Hort., is a large-fld. form offered in the trade. G.C. III. 55:442. Var. *Richentreichii*, Hort., is offered in the trade as a smaller form, about 6 in. high.

32. *Saxifraga*, Linn. (*S. petræa*, Waldst. & Kit., not Adams). Perennial, somewhat shrubby, densely caespitose, bright green: sts. numerous, 3–10 in. high, ascending, filiform, glabrous or scabrous-puberulent, viscid above: lvs. linear or linear-lanceolate, acute, glabrous or scabrous-puberulent, margin serrulate-ciliate: fls. whitish, very often solitary or in 2–3-fld. cymes, erect on very long pedicels; calyx tubular-clavate, glabrous, 10-striate, striæ green or reddish, puberulent; petals 2-parted, the lobes oblong: caps. ovoid-oblong. Eu. and Asia Minor. L.B.C. 5:454.

33. *odontopétala*, Fenzl. Perennial, densely pubescent: sts. 4-6 in. long, leafy, subsimple, glandular-villous above: lvs. lanceolate or linear-lanceolate, 1-nerved, acute or somewhat obtuse: fls. cymose, 1-7-fl., white; calyx pubescent, rather viscid, whitish, campanulate; petals 2-lobed: caps. ovate. Asia Minor and Syria.

34. *Elizabethæ*, Jan. Perennial, 4-6 in. high: sts. tufted, erect or ascending, viscid-pubescent: lvs. narrowly lanceolate, acute, the lower 2-3 in. long, gradually becoming smaller upward; panicle terminal; fls. bright rose to rose-purple, $1\frac{1}{2}$ in. across; calyx tubular, at first cylindrical, at length oval and bladdery, pale dull green, veined and margined purple; petals 2-lobed, white-clawed, blade cuneate-flabellate, margin crenate-dentate. Italy. B.M. 5400. G. 8:412.

35. *ciliata*, Pourr. Perennial, 3-6 in. high, pubescent, cespitose from a woody rhizome: sts. slender, simple, or slightly branched, nearly naked: lvs. of the rosette and lower st. linear-lanceolate or linear, the upper shortened and gradually narrowed from a broadened base: fls. in a few-fl. cincinnus, pedicelled, white or ivory-white; calyx clavate, short-pubescent, green-, red-brown-, or purplish striate; petals 2-lobed. Eu.

36. *rêpens*, Patrin. Perennial, 8-10 in. high, with a long repent root: sts. several, erect, simple or branched, more or less scabrous-pubescent: lvs. narrowly oblong or lanceolate, acute: fls. white, racemose-paniculate on opposite, axillary, 1-5-fl. peduncles; calyx cylindrical-clavate, inflated, 10-striate, pubescent-villous; petals 2-cut, the segms. oblong, obtuse, the claw glabrous. Russia, E. Siberia, Caucasus, China and Japan, and in N. Alaska.

37. *Reichenbachii*, Vis.; also spelled *Reichenbachiana* in the trade. Perennial, miniature, shrub-like, tufted: sts. somewhat woody at base, puberulent below, glabrous, somewhat viscid above: lower lvs. oblanceolate-spatulate, acute, ciliate on the ribs and margin; upper lvs. linear, acute: fls. white, racemose-paniculate, nodding; peduncles usually 1-fl.; calyx linear-clavate, 10-nerved, nerves red or green, margin of teeth lanuginous; petals obovate, 2-parted: caps. oval-oblong. Dalmatia.

38. *rupéstris*, Linn. Perennial, 2-8 in. high, loosely cespitose, glabrous: sts. numerous, erect from a branched base, $1\frac{1}{2}$ -7 in. high: lvs. lanceolate, acute, the lower attenuate at base: fls. flesh-color, in repeatedly dichotomous cymes, numerous, long-pedicelled; the pedicels filiform; calyx oboconical, base slightly umbilicate; petals obovate, deeply emarginate: caps. ovoid-oblong. Eu.

39. *caucásica*, Boiss. Perennial, 4-5 in. high, velutinous: caudicles filiform, nude: sts. ascending from below the rosette: lvs. in a rosette, oblong-lanceolate, elongated; cauline lvs. abbreviated: fls. 1, often 2-3 to a st., subsessile, white; calyx rather softly glandular-hairy, 10-nerved, narrowly cylindrical; petals obovate. Caucasus.—Closely allied to *S. valesia*, from which it differs in being velvety instead of glandular, in having shorter cauline lvs. and almost sessile, instead of long-peduncled fls. and not inflated calyx.

40. *vallèsia*, Linn. Perennial, cespitose, about 4 in. high, viscid-pubescent: sts. assurgent, slightly branched: lowest lvs. spatulate, others lanceolate; cauline lvs. long: fls. long-peduncled, terminal, rarely in pairs; calyx very long, glandular-pubescent, somewhat inflated after anthesis; petals bifid, rose-violet above, greenish beneath, claw ciliate. High Alps.

41. *Hookeri*, Nutt. Perennial, tomentose-pubescent: sts. many, decumbent, 6-10 in. high, slender: lvs. 2-3 in. long, the lower elliptic-spatulate, narrowed to the petiole; the remainder elliptic-lanceolate, acute, both surfaces pubescent: fls. solitary in the lf.-axils or sometimes in terminal or axillary few-fl. cymes, $2\frac{1}{2}$ in. across, pale pink; calyx soon turgid, 10-nerved, veins

obscure green, with membranaceous edges; petals ciliate-clawed, limb broad, 4-cleft. Ore. and Calif. B.M. 6051. F.S. 20:2093. G.C. III. 52:44. G. 34:643. Gn. 79, p. 389.

42. *pusilla*, Waldst. & Kit. Perennial, dwarf, villous on the petioles and at the base of the sts., viscous above, cespitose, many-stemmed: sts. low, slender, leafy, dichotomous: lvs. radical, spatulate, the others short-lanceolate: peduncles long, capillary, 1 (rarely 2) -fl.: calyx glabrous or minutely glandulose, turbinate; petals glabrous-clawed, blade white, obtuse, 4-toothed: caps. ovate-globose. S. Eu.—Considered by some to be only a variety of *S. quadrifida*.

43. *Schäfta*, Gmel.; also spelled *Schaftæ*. Perennial, 3-6 in. high, pubescent-scabrous: roots woody: sts. many, arising laterally from the rosettes, weak and procumbent, short, simple or slightly branched: lvs. rosulate, small, obovate-oblong, acute: fls. rose or purple, 1-5, axillary and terminal, solitary; calyx somewhat hirsute, reddish, 10-nerved, long, cylindrical, not inflated; petals broadly obovate, notched, with 2 scales at their base, claw glabrous. June-Oct. Caucasus. B.R. 32:20. F.S. 3, p. 286C. Gn. 78, p. 135.

44. *pennsylvànica*, Michx. (*S. caroliniana*, Walt.?). WILD PINK. Perennial, 6-9 in. high, from a strong taproot, viscid-pubescent: sts. few: lvs. mostly basal, spatulate or oblanceolate, acutish, base tapering to the long, ciliate petioles; cauline lvs. 2-3 pairs, shorter, lanceolate or narrowly oblong: fls. rose or white, in small, dense, terminal cymes; calyx purplish, clavate; petals obovate, claw glabrous, appendaged, 2-lobed. Apr., May. E. N. Amer., New England to S. C. and Ky. B.R. 247. L.B.C. 1:41 (as *S. incarnata*). B.B. (ed. 2) 2:65.—*S. caroliniana* is accepted by some authors as the name of this species, but there is considerable doubt as to the identity of Walter's species and it is questionable whether the plant he described is *S. pennsylvànica*.

S. Schafta, Hort., is probably a misspelling of *S. Schaftæ*.—*S. Correoniæna*, Hort., is offered as a rare plant growing in "compact tufts, with rosy pink fls. which almost resemble minute roses."—*S. graminifolia*, Hort., is not recognizable, as there are three plants going under that name.—*S. Kiabehiana*, Hort., may be *S. multicaulis*.—*S. orientalis*, Mill., is according to Miller a plant with st. erect, hirsute: lvs. nerved: fls. purplish; calyx conical. It is not treated botanically by Williams, DeCandolle, Boissier, Nicholson, or Voss, but is offered in the trade as a perennial, 2-2½ ft. high: fls. bright rose, in a head. Var. *alba*, Hort. and var. *compacta*, Hort., are also offered.—*S. pteris grandiflora*, Hort., is offered in the trade; the species is unknown botanically.—*S. Wardsii*, Hort., is likened to *S. Schafta* on a large scale: said to grow about 1 ft. high, to have a loose graceful habit and an abundance of bright pink fls. Offered in the trade.

F. TRACY HUBBARD.†

SILK-COTTON TREE: *Ceiba*. S. Flower: *Albizia*. S. Oak: *Grevillea robusta*. S. Tree: *Albizia julibrissin*. S. Vine: *Periploca græca*. S.-weed: *Asclepias*.

SÍLPHIUM (from the Greek name of an umbelliferous plant of northern Africa). *Compósitæ*. ROSIN-WEED. Tall-growing hardy perennial herbs native of the United States which are grown for their rather large sunflower-like heads of flowers which, except in one species, are yellow.

Leaves opposite, alternate or verticillate, often forming water-holding cups by perfoliation of the st.: heads many-fl.; involucre of thick, somewhat foliaceous bracts; ray-fls. or at least their ovaries in more than 1 series, fertile, and with elongated exserted deciduous ligules: achenes much flattened, falling free or only with the subtending bract.—About 25 species. Silphiums are of easy cult. in any good soil. They require full sunlight and are prop. by division or seed.

A. *Foliage much cut.*

laciniatum, Linn. COMPASS PLANT. St. about 6 ft. high, leafy at the base, much less so above, very rough: lvs. 1 ft. long or more, once or twice pinnately parted, the lobes oblong or lanceolate: fl.-heads several, sessile or short-peduncled, 2-5 in. across; rays 20-30.

July–Sept. Ohio, west and south. B.B. (ed. 2) 3:461.—It is said of this species that the st.-lvs. tend to point north and south.

AA. *Foliage not cut.*

B. *St.-lvs. small.*

terebinthinaceum, Jacq. PRAIRIE DOCK. St. about 6 ft. high, nearly or quite smooth: lvs. nearly all basal, usually 1 ft. long, ovate, cordate, dentate: fl.-heads $1\frac{1}{2}$ –3 in. across; rays 12–20. July–Sept.—Ont. and Ohio to Iowa and La. B.B. (ed. 2) 3:462.—A striking and decorative herb.

BB. *St.-lvs. large.*

C. *Lvs. connate-perfoliate.*

perfoliatum, Linn. (*S. erythrocarilon*, Bernh.). CUP PLANT. INDIAN CUP. St. square, usually dentate, branched above, about 6 ft. high: lvs. thin, ovate or deltoid-ovate, the lower contracted into margined petioles, the upper opposite, connate-perfoliate: fl.-heads 2–3 in. across, with 20–30 rays. July, Aug. Ont. to S. D. and Ga. B.B. (ed. 2) 3:460. G.W. 11, p. 473.

CC. *Lvs. petioled or simply sessile.*

integrifolium, Michx. St. 2–6 ft., obtusely 4-angled to terete, corymbosely branched above: lvs. lanceolate-ovate to ovate-lanceolate, opposite: fl.-heads numerous, 1–2 in. across, with 15–25 rays. Aug., Sept. Western prairies. B.B. (ed. 2) 3:460. N. TAYLOR.†

SILYBUM (an old Greek name applied by Dioscorides to some thistle-like plants). *Compositæ*. Erect, glabrous herbs, sometimes grown in European gardens for ornament and also for the edible heads, roots, and lvs.: lvs. alternate, white-maculate above, sinuate-lobed or pinnatifid, the teeth and lobes spiny: heads large, solitary, terminal, nodding, homogamous; involucre broadly subglobose, the bracts in many rows: fls. purplish, all perfect; corolla-tube slender, limb 5-cleft to the middle or base: achenes smooth, obovate, oblong.—Two species, Eu., Afr., and Asia.

Mariànum, Gaertn. (*Cárduus Mariànus*, Linn. *Mariàna lactea*, Groves). ST. MARY'S, BLESSED, or HOLY THISTLE. Annual or biennial, shining: st. 1–4 ft. high, grooved not winged: lvs. large, with strong spines: heads 1–2 in. diam.; involucre bracts leathery with a spine $\frac{1}{2}$ – $\frac{3}{4}$ in. long, the outermost mucronate; receptacle fleshy: fls. rose-purple: achenes transversely wrinkled or smooth, black or gray. S. Eu., N. Afr., and Asia, also intro. in many places, including N. Amer.; naturalized on the Pacific coast. F. TRACY HUBBARD.

SIMARÛBA (the Caribbean name of *S. amara*); also spelled *Simarouba*. *Simarubaceæ*. Evergreen trees sometimes grown in the warmhouse, or hardy outdoors in the far S.: lvs. alternate, abruptly pinnate; the lfts. alternate, entire, leathery: fls. somewhat cymose, in axillary or terminal elongated and branched panicles, dioecious; calyx small, 5-lobed, imbricated; petals 5, spreading at the top, imbricated; stamens 10 in the male fl.; ovary deeply 5-parted in the female fl.: drupes 1–5, sessile, spreading.—About 7 species, Trop. Amer.

amàra, Aubl. (*S. officinalis*, DC.). A tall tree: lfts. oblong or oblong-lanceolate, mucronate with a bluntish point, green on both surfaces, glabrous or pubescent beneath: panicle exceeded by the lvs.: fls. yellowish white; petals spreading. W. Indies (probably not Porto Rico) and Trop. Amer.—This yields the drug known as *simaruba-bark*.

Tùlæ, Urban. A tree 25–50 ft. high: lfts. elliptic-oblong, short-pointed: branches of the corymb (as well as the petioles) purple-tinted: fls. bright carmine; petals much longer than *S. amara*, and having smooth, staminal scales. Porto Rico. Gt. 36:1298.

F. TRACY HUBBARD.

SIMMÓNDIA (for the naturalist, F. W. Simmonds). *Buxaceæ*. Evergreen shrubs, sometimes cult. for ornament or for the oily seed and edible fr.: lvs. opposite: fls. dioecious, in the lf.-axils, apetalous; sepals imbricate; staminate fls. in clusters; stamens numerous; pistillate fls. single; ovary 3-celled, 1 ovule in each cell. A single species. Related to *Buxus*.

californica, Nutt. PIGNUT. JOJOBA. A much-branched shrub, 5–15 ft. high: lvs. small, sessile, entire, coriaceous, oblong-lanceolate, obtuse: fls. small. S.W. Calif. to W. Mex.

J. B. S. NORTON.

SINNINGIA (for Wilhelm Sinning, gardener at the University of Bonn). Including *Dolichodèira*, *Ligeria*, and *Rosanòvia*. *Gesneriaceæ*. Tropical herbs with handsome tubular flowers, of glasshouse culture; includes the florists' *gloxinia*.

Pubescent or villous, from a tuberous rhizome: lvs. opposite, usually large, petioled, the floral ones reduced to bracts: fls. usually large, solitary or fascicled in the axils, pedicelled; calyx-tube shortly and broadly turbinate, adnate, 5-angled or 5-winged, the limb foliaceous, broadly 5-cleft or -parted; corolla-tube nearly equal at the base or the posterior gibbous, long or broadly cylindrical, the upper part swollen or bell-shaped; lobes 5, spreading, or the 2 posterior smaller; stamens included, attached to the tube of the corolla; anthers broad, the cells confluent at the apex; glands of the disk 5, distinct, or the 2 posterior more crowded together or connate; ovary half inferior; style dilated at the tip; stigma concave, entire or slightly 2-lobed.—Species 20–25, Brazil. Allied to *Gesnera*, *Isoloma*, and *Achimenes*, and of similar cultural requirements. The genus includes the cult. *gloxinia*, which is properly *Sinningia speciosa*, Benth. & Hook., but which is treated in this book under *Gloxinia*. Other than this species, the *sinningias* are little known horticulturally, although some of the species have much merit.

speciòsa, Benth. & Hook. (*Gloxinia speciòsa*, Lodd. *Ligeria speciòsa*, Deene.). St. short or not evident: lvs. oblong, petiolate, obtuse or acutish, villous-hairy, convex on top, usually attenuate at base, crenate: peduncles, with fls., about the length of the lvs.: fls. large, tubular, showy, usually violet or purplish; calyx-lobes ovate-lanceolate and somewhat villous, longer than calyx-tube; corolla broadly campanulate. Brazil. Variable, giving rise to such forms as var. *caulescens*, Hanst. (*Gloxinia caulescens*, Lindl.), with thick elongated st. and larger lvs. B.R. 1127. L.B.C. 16:1566. Var. *macrophylla*, Hanst. (*Gloxinia speciòsa* var. *macrophylla*, Hook.), has large white-nerved lvs. B.M. 3934. Var. *albiflora*, Hanst. (*Gloxinia speciòsa* var. *albiflora*, Hook.). White-fl. B.M. 3206. Var. *rùbra*, Hanst. (*Gloxinia rùbra*, Paxt.). Fls. beautiful red. P.M. 7:271. From this species, and perhaps from hybrid offspring, have descended the florists' *gloxinias*. To the historical discussion on pp. 1350 and 1351, Vol. III, may be added the following quotation from T. A. Sprague, G.C. III, 36, p. 88: "The turning-point in the history of our cultivated 'gloxinias,' however, was in 1845, when an erect and regular-flowered plant was raised by Mr. John Fyfe, gardener at Rothesay, Bute; this had a white corolla with a violet center, and five perfect stamens, instead of the four usual in *Gesneriaceæ*. Unfortunately for the systematic botanist, no exact record of its parentage was made, though in *Flore des Serres*, t. 311, where it was figured three years later, *Sinningia speciosa* is stated to have been one of its parents."

Regina, Sprague (*Gesneria Regina*, Hort.). Handsome plant about 9 in. high: lvs. broad-ovate with auriculate-cordate base and acutish apex, 4–8 in. long, somewhat velutinous above and glabrous beneath, white-veined, crenate: fls. pale violet, drooping, long-stalked, 4–6 together from the axils, and "as two suc-

cessive pairs of leaves are usually close together on the stem, the effect is that of two many-flowered whorls, and is very fine." Brazil. G.C. III. 36:201. B.M. 8182. Gt. 53, p. 525. G.W. 9, p. 277. A handsome plant, with long flowering period. Var. *hybrida*, Hort., is a garden hybrid with much larger fls. Var. *grandiflora*, Hort., is advertised, the fls. "several times larger than the type, and well displayed above the handsome dark green and purplish red foliage."

conspicua, Nichols. (*Rosandwia conspicua*, Regel). Root tuberous: st. 1 ft. high: lvs. ovate-oblong, short-acuminate, somewhat heart-shaped at the base and dentate: fls. yellow, paler on the outside, marked on the lower part of the tube with purple dots and lines; calyx-tube entirely united with the ovary, equally 5-parted, the segms. lanceolate, spreading; corolla-tube obliquely and narrowly campanulate, swollen and recurved at the base; glands of the disk 2: caps. 1-celled; seeds many.

ornata, Benth. & Hook. (*Rosandwia ornata*, Van Houtte). A hybrid of the above species with a garden variety of *Gloxinia* with fls. of a bright red; the result is a plant resembling *S. conspicua*, but differing in having the lvs. tinted on the veins and petioles with purple and in having a somewhat more elegantly shaped fl., pure white with purple lines on the outside of the corolla-tube and the inside of a yellowish green, lined with purple. F.S. 23:2423.—Probably not now in the market.

L. H. B.†

SINOFRANCHÈTIA (for Adrien Franchet, French botanist who wrote much on Chinese botany). *Lardizabalaceæ*. Deciduous climbing shrub allied to *Holboellia*, but easily distinguished by the deciduous lvs., by the rounded small sepals of the fls. borne in very long racemes and by the small berry-like frs. The only species is *S. chinensis*, Hemsl. (*Holboellia chinensis*, Diels). Twining, to 30 ft., glabrous: lvs. long-petioled, 3-foliate; lfts. stalked, short-acuminate, broadly cuneate at the base, entire, the terminal broadly obovate, 4-5 in. long, the lateral lfts. obliquely ovate: racemes axillary, 8-12 in. long; fls. unisexual, short-stalked, $\frac{1}{4}$ in. across, white striped brownish; sepals obovate; stamens 6, free, short: carpels 3, developing into ovoid many-seeded, bluish purple berries about $\frac{3}{4}$ in. across. Cent. China. H.I. 29:2842.—The long racemes of bluish purple berries are strikingly handsome: the plant has proved perfectly hardy in southern England, but is tender at the Arnold Arboretum. Prop. is by seeds and by layers, possibly also by cuttings like *akebia*.

ALFRED REHDER.

SINOMÈNIUM (*Sina*, China, and Greek, *men*, moon, meaning Chinese moon-seed). *Menispermaceæ*. A shrubby vine from E. Asia closely related to *Menispermum* and *Cocculus*; from the first it differs in the parts of the fl. being arranged in whorls and in the 9-12 stamens, and from the second chiefly in the structure of the flattened curved seed: lvs. deciduous, alternate, long-petioled: fls. dioecious, small, in axillary and terminal panicles; sepals 6, pilose outside; petals 6, inflexed at the base and inclosing the filaments; the pistillate fls. with 9 staminodes and 3 carpels with recurved styles: fr. a drupe with a compressed crescent-shaped stone ribbed on the back. A handsome vigorous-growing twining vine with large lustrous often lobed lvs. remaining green until late in autumn, with inconspicuous fls. in long pendulous racemes and bluish black frs. It has proved only half-hardy at the Arnold Arboretum. Prop. like *cocculus* and *menispermum*.

acutum, Rehd. & Wilson (*S. diversifolium*, Diels. *Menispermum acutum*, Thunb. *Cocculus diversifolius*, Miq., not DC. *C. heterophyllum*, Hemsl. & Wilson. *C. varifolius*, Hort.). Twining, to 20 ft.: branchlets terete, striped, glabrous: lvs. long-stalked, ovate, acuminate, usually cordate at the base, palmately 5-7-nerved,

entire or palmately lobed, rarely sagittate with 2 lobes at the base only, glabrous, 4-7 in. long: fls. $\frac{1}{2}$ in. across, greenish, in slender panicles 4-8 in. long: drupes compressed, bluish black, $\frac{1}{4}$ in. across, in pendulous panicles to 8 in. long. June; fr. in Sept. and Oct. Japan and China. G.C. III. 52:411. Var. *cinereum*, Rehd. & Wilson. Lvs. densely grayish pubescent beneath.

ALFRED REHDER.

SINOWILSONIA (for Ernest Henry Wilson, who collected extensively in China during 1900-1910 and intro. numerous new plants into cult.). *Hamamelidaceæ*. A deciduous tree similar in foliage to *Hamamelis*, but in its fls. more closely related to *Corylopsis*, from which it is chiefly distinguished by the unisexual, apetalous fls., and the tubular-urceolate calyx-tube: fls. in pendulous racemes; tube of the calyx urceolate, inclosing the ovary, with obovate-spatulate lobes; petals wanting; the pistillate fls. with 5 staminodes opposite to the sepals; ovary with 2 long and slender styles: fr. a dehiscent 2-seeded woody caps. The only species is *S. Henryi*, Hemsl. Shrub or tree, to 25 ft., more or less stellate-pubescent: lvs. short-petioled, membranous, broadly obovate to elliptic, acute or short-acuminate, denticulate, 4-6 in. long: calyx-tube yellowish, stellate-tomentose, nearly $\frac{1}{4}$ in. long: caps. sessile, nearly $\frac{1}{2}$ in. long; seeds black. May. Cent. and W. China. H.I. 29:2817.—Botanically interesting, but without particular ornamental qualities; has proved hardy at the Arnold Arboretum. Prop. is by seeds and probably by layers and by grafting on *hamamelis*.

ALFRED REHDER.

SIPÀNEA (native name in Guiana). *Rubiaceæ*. Annual or perennial herbs, hispid-setose, pilose or glabrate, erect or prostrate, with terete branches: lvs. opposite, petiolate, ovate or lanceolate; stipules linear, elongate, persistent: fls. paniculate or cymose, the cymes in corymbs, axillary, terminal or dichotomously disposed, white or rose, the throat frequently golden villous; calyx-tube turbinate or ovoid, the limb with 5 elongate-subulate, persistent lobes; corolla funnelliform or salver-shaped, tube elongated with the throat dilated, the limb with 5 equal, broad-ovate spreading lobes; stamens 5; disk annular; ovary 2-celled: caps. ovoid or subglobose, leathery.—About 5 species, Trop. Amer. *S. carnea*, Neumann. Perennial herb, about 3 ft. or more high: lvs. oval, lanceolate, acute: fls. pale rose-violet, arranged in a corymb; corolla-tube cylindrical, 5-parted, oval, acute: fr. hemispherical. Cent. Amer. H.U. 4, p. 193. R.H. 1843:445.

SIPHOCAMPYLUS (Greek, *siphon*, tube, and *kampylos*, curved, referring to corolla); sometimes misspelled *Syphocampylus*. *Campanulaceæ*. Herbs, subshrubs, or shrubs, sometimes climbing, glabrous, hirsute or stellate-tomentose, adapted to the warm or coolhouse: lvs. alternate, rarely verticillate, entire or denticulate, rarely incise-dentate or pinnately lobed or divided: peduncles 1-fld., axillary or corymbosely grouped at the ends of the branches or laxly racemose: fls. often rather large, red, orange, or purplish, rarely green; calyx 5-lobed; corolla straight or incurved: caps. loculicidally 2-valved.—About 100 species, Trop. Amer.

betulaefolius, Don. Height 2-3 ft.: st. woody at base: branches rounded: lvs. alternate, petiolate, 3-4 in. long, cordate, acuminate, doubly serrate, nearly glabrous: peduncles 1-fld., as long as the lvs., thickened upward: calyx-segms. long awl-shaped, with a few notches; corolla $2\frac{1}{2}$ -3 in. long, tube vermilion, limb yellow. Brazil. B.M. 3973. H.U. 5, p. 97.—Tender perennial, not cult. in Amer., but interesting as one supposed parent of *Centropogon Lucyanus*, itself of little value.

S. bicolor, Don=*Lobelia laxiflora*, HBK.—*S. giganteus*, Don (*Tupa salicifolia*, Don) grows 14 ft. high: lvs. lanceolate, 6-9 in. long, scarcely petioled: fls. reddish yellow; corolla falcate, velvety. Ecuador.—*S. Lindleyi*, Lem., has ovate-oblong, glandulose-serrate

lvs. and approximate red fls. Colombia. J.F. 2:142.—*S. Orbignianus*, A. DC., is herbaceous; has ternate, ovate-acuminate, short-petioled lvs. and numerous red-and-yellow fls. in the upper axils. Bolivia. J.F. 4:425.—*S. rugosus*, A. DC., has pendulous branches, ovate-rotund coriaceous and rugose lvs., the corolla with lanceolate, acute lobes and the caps. 10-angled. Peru. H.U. 3, p. 368.

F. TRACY HUBBARD.†

SIPHONIA: *Hevea*.

SISYRINCHIUM (an old Greek name first applied to some other plant). *Iridaceæ*. SATIN FLOWER. BLUE-EYED GRASS. RUSH LILY. Hardy or half-hardy perennials, usually with fibrous roots, sometimes used in the hardy border.

Stems simple or branched, 2-edged or winged: lvs. grass-like, lanceolate or terete: fls. small, fugacious, in umbellate clusters from a usually 2-lvd. spathe, blue or yellow, perianth nearly flat or bell-shaped, segms. 6, nearly alike: caps. globular, 3-angled.—About 150 species, all American, mostly in moist fields and sandy places and along shores. The species are of easy cult. in any good garden soil. They are very little known as horticultural subjects.

A. *Fls. yellow.*

B. *St. leafless.*

californicum, Dry. (*Marica californica*, Ker-Gawl.). A half-hardy perennial: st. $1\frac{1}{2}$ ft. high, 2 lines through, broadly winged: lvs. many, shorter than the st., about $\frac{1}{2}$ in. broad: spathe 3-6 fld.: segms. of perianth yellow, lined with brown, $\frac{1}{2}$ in. long: caps. oblong. Calif. to Ore. B.M. 983.—Swampy grounds.

BB. *St. ly-bearing.*

C. *The st. slightly 2-edged.*

tenuifolium, Humb. & Bonpl. A half-hardy perennial: roots fleshy, fibrous: st. $\frac{1}{4}$ –1 ft. high, often branched low down: lvs. subterete or narrowly linear: spathes 3-4 fld.: segms. of perianth pale yellow, $\frac{1}{2}$ in. long. Mountains of Mex. B.M. 2117; 2313.

striatum, Smith (*S. lutescens*, Lodd. *Marica striata*, Ker-Gawl.). Perennial, 1-3 ft.: sts. compressed-ancipital, leafy: lvs. ensiform, glaucous, radical equitantly imbricate toward their base, cauline remote, clasping: fls. in sessile fascicles laxly and closely disposed along the flexuous rachis, yellow, darker striate at center, about $\frac{3}{4}$ –1 in. across; perianth-segms. cuneate-ligulate, the outer ones twice as broad as the inner, blades rotately spreading, obtuse and mucronate. Chile and Argentina. B.M. 701. L.B.C. 19:1870. Gn. 70, p. 202. R.H. 1910, p. 457.

CC. *The st. broadly winged.*

convolutum, Noeca. A tender perennial: root fibrous, slender: st. about 1 ft. high, usually forked: lvs. linear: spathes 3-4 fld.: segms. of perianth yellow, veined with brown, $\frac{1}{2}$ in. long. Trop. Amer.

AA. *Fls. purple, blue, or white.*

B. *St. terete.*

grandiflorum, Douglas (*S. Douglasii*, A. Dietr.). A hardy perennial: root-fibers slender, long: st. simple, about 1 ft.: lvs. short, sheathing the lower part of the st.: fls. 2-3, cernuous; perianth-segms. bright purple, rarely white, $\frac{3}{4}$ in. long. May, June. N. W. U. S. B.M. 3509. B.R. 1364. G. 2:100; 5:559.—This is possibly the handsomest species in the trade. Var. **album**, Hort., is also offered and is equally desirable.

BB. *St. flat.*

C. *Spathes equal in length.*

graminoides, Bicknell (*S. anceps*, Wats., not Cav.). A hardy perennial: st. winged, about 1 ft. high, usually terminating in 2 unequal branches, subtended by a lf.: lvs. nearly equaling the st., grass-like, 1-3 lines wide: spathes about 1 in. long, 2-4 fld.: pedicels longer than the spathes: fls. blue, $\frac{1}{2}$ – $\frac{3}{4}$ in. across. April-June. E. U. S. B.B. 1:453.

CC. *Spathes very unequal in length.*

angustifolium, Mill. (*S. anceps*, Cav. *S. bermudianum*, Authors). A hardy perennial: root-fibers long: st. about 1 ft. high, $1\frac{1}{2}$ lines through, with 2-3 clusters on long-winged peduncles: lvs. linear, shorter than the st., 1- $1\frac{1}{2}$ lines wide: spathes 1-4 fld., about 1 in. long: pedicels about 8 lines long. May-Aug. Maine to Va., west to Colo. Var. **bellum**, Hort. (*S. bellum*, Wats.). Sts. more narrowly winged, usually without any lf. below the fork: spathes shorter: pedicels longer. Calif., New Mex.

mucronatum, Michx. Hardy perennial similar to the last: sts. narrowly winged: spathes usually purpletinged, not gibbous; outer bract with the margin united a little above the base, $\frac{3}{4}$ – $2\frac{3}{4}$ in. long, the inner $\frac{1}{4}$ – $\frac{3}{4}$ in. long: perianth violet (rarely white): caps. straw- or greenish yellow. W. Mass. to Va. and Mich. B.B. (ed. 2) 1:544.

F. W. BARCLAY.

F. TRACY HUBBARD.†

SITOLØBIUM (name refers to the grain-like fructification). *Polypodiaceæ*. Under this name one fern is still listed, but the group now forms a section of *Dicksonia* or *Dennstaedtia* characterized by prostrate rhizome and a cup-shaped nearly spherical involucre placed at the base of the depression of the lobes. The fern in question is *Dennstaedtia cicutaria*, Moore (*Sitolobium cicutarium*, J. Smith. *Dicksonia cicutaria*, Hook. & Baker), a W. Indian species with bipinnate lvs.: lower pinnae 12-18 in. long and 6 in. broad, with deeply cut linear-acuminate pinnules, the segms oblong-deltoid and deeply cut.

SÏUM (from *Sion*, old Greek name used by Dioscorides). *Umbelliferae*. Glabrous herbs, including one of economic value, *S. Sisarum* or skirret (which see), the roots of which are used as a vegetable: lvs. pinnate, the pinnae dentate: umbels composite, terminal or lateral; involucre and involucre bracts numerous: fls. white; calyx-teeth acute; petals inflexed: fr. ovate or oblong, laterally compressed or constricted at the junction of carpels.—About 4 species, northern hemisphere, also one species in S. Afr., apt to be subaquatic.

Sisarum, Linn. SKIRRET. Plant, 3-4 ft. high, tuberous-rooted: lvs. pinnatisect; segms. oblong-acute, serrate: involucre 5-lvd., reflexed. E. Asia.

latifolium, Linn. WATER PARSNIP. Sts. 3-5 ft. high, angular, furrowed and erect: lvs. pinnate; lfts. oblong-lanceolate, evenly serrate, pointed: umbels terminal; involucre lvs. many, lanceolate. Ditches and rivers, England.—Like *Ferula* and certain other umbelliferous plants, it is valued more for its stately habit and handsome foliage than for its fls. F. TRACY HUBBARD.

SKIMMIA (Japanese, *Skimmi*, meaning a hurtful fruit). *Rutaceæ*. Ornamental woody plants grown chiefly for the bright red berries and the handsome foliage.

Evergreen glabrous shrubs: lvs. alternate, short-petioled, entire, dotted with translucent glands: fls. perfect or dioecious, the staminate fragrant and in large panicles; sepals and petals 4-5; stamens 4-5; style with 2-5-lobed stigma; ovary 2-5-loculed: fr. a drupe with 2-4 1-seeded stones.—Four species from the Himalayas to China and Japan.

The skimmias are densely branched, usually low shrubs with medium-sized generally oblong acute leaves, small white flowers in terminal panicles and showy bright red, rarely black, berry-like fruit. They are tender, not being reliably hardy as far north as Washington, D. C. *S. Fortunei* is somewhat hardier than *S. japonica*. Handsome shrubs for borders of evergreen shrubberies and especially valuable for planting in cities, as they belong to the best smoke-enduring evergreen shrubs; they are particularly beautiful when

covered with their bright red fruits, which are retained through the whole winter if not eaten by birds. In the greenhouse two crops of berries on a plant may be seen occasionally. The skimmias are of rather slow growth and thrive best in a sandy loamy soil, but also grow well in strong clay; they prefer a partly shaded situation. On account of their handsome fruits they are sometimes cultivated in pots in a sandy compost of peat and loam. As the skimmias are polygamous and mostly unisexual, it will be necessary to plant staminate plants among the pistillate ones to secure well-fruited specimens. Propagation is by seeds sown in fall or stratified and by cuttings under glass with gentle bottom heat. William Scott writes: "Seeds sown in the fall and grown along in a coolhouse during winter can be planted out in a good loam the following spring, when they will make a vigorous growth, and can be lifted the following October. Their red berries make them very desirable as a Christmas berry plant."

japonica, Thunb. (*S. oblata*, Moore. *S. fragrans*, Carr. *S. fragrantissima*, Hort.). Shrub, 5 ft. high, except the minutely pubescent infl. quite glabrous: lvs. crowded at the ends of the branchlets. Short-petioled, elliptic-oblong to oblong-obovate, narrowed at both ends, obtusely pointed, bright or yellowish green above, yellowish green beneath, $3\frac{1}{2}$ -5 in. long; panicles 2- $3\frac{1}{2}$ in. long; fls. polygamous, usually 3-merous, yellowish white: fr. coral-red or bright scarlet, globose or depressed-globose. $\frac{1}{4}$ in. across. Spring. Japan. S.Z. 1:68. B.M. 8038. G.C. II. 25, p. 244; I.I. 5, pp. 521, 524. Gn. 7, p. 183; 35, p. 480; 42, p. 135. J.H. II. 30, p. 525; 66:175; 70:343. R.H. 1869, p. 259; 1880, p. 56. F. 1865, p. 161. G.W. 5, p. 261.—*S. fragrans* and *S. fragrantissima* are names of the staminate plant; *S. oblata* of the pistillate. Var. *ovata*, Rehd. (*S. oblata ovata*, Carr.), has larger and broader lvs. Var. *Veitchii*, Rehd. (*S. oblata Veitchii*, Carr.), has obovate lvs. and often perfect fls. R.H. 1880, p. 57.

Fórtunei, Mast. (*S. japonica*, Lindl.). Similar to the preceding but of dwarfer habit: lvs. lanceolate or oblong-lanceolate, acuminate, dark green above, light green beneath, $3\frac{1}{2}$ -10 in. long; fls. white, in oblong-ovate panicles, perfect; fr. obovate, dull crimson-red. Spring. China. G.C. II. 25, p. 245 (as *S. oblata*); III. 5, p. 525. The following as *S. japonica*: B.M. 4719; F.S. 7, p. 39; Gn. 7, p. 183, and 8, p. 519; G. 1:40; R.H. 1869, p. 259, and 1880, p. 56. This species fruits more freely than the preceding. Var. *rubella*, Rehd. Peduncles, pedicels, and buds reddish; staminate form. R.H. 1874:311; 1885, p. 189. Var. *argentea*, Mast., has the lvs. bordered with white. A hybrid between this and the preceding species is probably *S. intermedia*, Carr., with narrow oblong-elliptic lvs. dark green above. To this hybrid belong also *S. Foremanii*, Hort., with lanceolate or oblanceolate yellowish green lvs. and subglobose and obovate fr. on the same panicle (G.C. III.

5:553. Gn. 61, p. 160; 67, p. 57) and *S. Rogersii*, Hort., with similar but deep green lvs. and globose squarish fr.

S. Laureola, Sieb. & Zucc. Shrub, 5 ft. high, of a strong aromatic odor when bruised: lvs. narrow-oblong to obovate, acute or acuminate, bright green; fls. 5-merous. Himalayas. G. 32:255.—*S. melanocarpa*, Rehd. & Wilson. Shrub, or small tree, to 15 ft.: lvs. oblong-lanceolate or lanceolate, dark green and lustrous above, $1\frac{1}{2}$ - $3\frac{1}{2}$ in. long; fls. diceious, in panicles about $1\frac{1}{2}$ in. long; fr. purplish black, globose, $\frac{1}{2}$ in. across. W. China, Himalayas.

ALFRED REHDER.

SKIRRET (*Sium Sisarum*, Linn.) is a vegetable of minor importance, the roots of which are used like salsify or oyster plant. It is a hardy perennial umbelliferous herb, native to eastern Asia. It grows 3 to 4 feet high, has pinnate foliage and small white flowers in compound umbels. The roots grow in large clusters, something like those of a sweet potato or dahlia, but they are much longer, more cylindrical, and somewhat jointed. The roots have a sweet and slightly floury taste and, if well grown, are tender. The chief objection to this vegetable is the woody core, which must be removed before cooking, as it is not easily separated from the fleshy part at the table and detracts from its quality. The thickness of the core varies greatly, no matter whether the plants are propagated by seed or otherwise.

Skirret needs a rich soil. The seeds may be sown in autumn or spring and the plants yield well the first season. For European practice Vilmorin recommends that the seedlings be grown in a seed-bed until they have made four or five leaves and then transplanted into permanent quarters. Sow the seed in drills $\frac{1}{2}$ inch deep, and thin out the seedlings to 8 inches in the row. The roots may be left outdoors in the ground all winter, but others advise storing them in sand or earth.

WILHELM MILLER.

SKUNK CABBAGE: *Symplocarpus foetidus*.

SLIPPER FLOWER: *Calceolaria*. Lady's: *Cypripedium*.

SLOE: *Prunus spinosa*.

SMALL-FRUIT: Blackberry, Blueberry, Currant, Dewberry, Gooseberry, Raspberry.

SMELÓWSKIA (named for Prof. T. Smelowski, botanist of St. Petersburg, died 1815). *Cruciferae*. Somewhat caespitose gray-white-tomentose perennial herbs, rather rare in cult., suitable for the rock-garden: lvs. pinnately or bipinnately cut; fls. racemose, without bracts, white or yellow, frequently small; sepals short, lax, uniform at the base: silique rather short, narrowed at both ends, somewhat 4-sided or laterally compressed; seeds few, arranged in one series.—About 10 species, Asia and N. Amer.

calycina, C. A. Mey. Low, tufted perennial, very variable in foliage: lvs. soft, usually deeply pinnatifid, with 2 or several pairs of linear to obovate, obtuse segms. and a terminal one: rarely a few lvs. entire: racemes at first dense and subcorymbose, but elongating in fr.: fls. white or nearly so; petals about 2 lines long. Arctic regions.—Recommended by some persons for rock-gardens, but it does not seem to be advertised in Amer. F. TRACY HUBBARD.†

SMILACINA (resembling smilax). *Liliaceae*. FALSE SOLOMON'S SEAL. Perennial herbs, with simple stems from rootstocks (Fig. 3620), used for the hardy border or the wild-garden.

Leaves alternate, nerved, and usually sessile: panicles or racemes terminal; fls. white or greenish white, sometimes fragrant; perianth 6-parted, spreading, withering-persistent; stamens 6; ovary 3-celled: berry globular, 1-2-seeded.—About 25 species, N. and Cent. Amer. and Temp. Asia. Vagnera is an older name for this genus and is used by some American writers; but on the principle of fifty years of established usage, *Smilacina* is retained in the "nomina conservanda" list of the Vienna Congress.

3620. Rootstock of *Smilacina racemosa*. The figures designate the position of the stalks in the different years. Between each of the figures or scars is a year's growth. ($\times\frac{1}{2}$)

Smilacinas are of easy culture in any good soil. They prefer a rich loam in a moist but not wet partly shaded place. They are handsome plants both in foliage and flower, particularly when growing with natural companions. *S. racemosa* is probably the most attractive.

The plants may be forced slowly for bloom in the late winter and early spring.

davurica, Turcz.; also spelled *dahurica*. St. many-lvd., rather pilose: lvs. alternate, semi-clasping, oblong, glabrous above, rather pilose beneath: racemes terminal; pedicels in pairs or ternate. Dahuria and Japan. — Related to *S. stellata*, which is distinguished by the solitary pedicel.

paniculata, Mart. & Gal. Glabrous herb: sts. erect: lvs. ovate-lanceolate, long-acuminate, 5-6 in. long, much narrowed at the very base, main nerves 5-7: panicle terminal, racemously branched, 2½ in. long and as much across, all parts snowy white: fls. about 4 lines across; perianth-segms. elliptic; ovary ovoid. Mex. B.M. 8539.

3621. *Smilacina racemosa*. (X about ½)

racemosa, Desf. (*Vagnèra racemosa*, Morong). Figs. 3620, 3621. Rootstock rather stout: st. 1-3 ft. high: lvs. 3-6 in. long, oblong-lanceolate or oval, sessile or nearly so: fls. numerous, in a panicle: berry ¼ in. through. In shaded or partly shaded places throughout the greater part of the U. S. B.B. (ed. 2) 1:515. A.G. 13:519.

sessilifolia, Nutt. (*Vagnèra sessilifolia*, Greene). Rootstock slender: st. 1-2 ft. high, slender: lvs. 2-6 in. long, lanceolate, acute, flat and spreading: raceme open, sessile, or short-peduncled: berry 3-5 lines through. Early summer. Pacific States.

stellata, Desf. (*Vagnèra stellata*, Morong). Very near to *S. sessilifolia*: lvs. usually folded and ascending: raceme shorter and more crowded. May, June. Moist soil, greater part of the U. S. B.B. (ed. 2) 1:516.

trifolia, Desf. (*Vagnèra trifolia*, Morong). Rootstock slender: st. 2-15 in. high: lvs. sessile, oval to oblong-lanceolate, 2-5 in. long: fls. in a simple raceme, few to several: berry ¼ in. through. Bogs and moist soil in the N. U. S. and Asia. B.B. (ed. 2) 1:516.

S. bifolia, Schult. f. = *Maianthemum bifolium*.

F. W. BARCLAY.

F. TRACY HUBBARD.†

SMILAX (ancient Greek name). *Liliacæ*. The greenbriers, useful for winter greens and outdoor planting.

Usually woody climbers with paired tendrils on the base of the petiole; sometimes shrubs or herbaceous perennials, young shoots little branched, old woody shoots becoming much branched above; shoots arising from a rootstock, slow-growing and woody or with large fleshy tubers; in some species with long creeping rhizomes: lower lvs. reduced to scales, the upper simple

or slightly lobed, 3-7 (or more) -nerved, deciduous to completely evergreen, usually variable in outline on different types of branches: fls. rather small, dicecious, usually numerous in axillary peduncled umbels; pedicels uniform in length: berries normally globose, 1-6-seeded, blackish or red.—Over 200 species generally distributed over the world.

The genus *Smilax*, of which there are twenty-five species native to the United States, has been used very little in this country for planting in ornamental grounds, its value as a decorative plant having been largely ignored. The vines of the wild plants have been gathered locally for decorations and *S. lanceolata*, the Florida smilax of the trade, is extensively shipped from the southern states to the northern centers for use in large decorations. Most of the common woody species of the North are unsuited for planting in restricted areas as they spread rapidly by underground stems. None of the native species listed below is ordinarily handled by nurserymen.

The smilax of florists is *Asparagus asparagoides*. See p. 3175; also p. 409, Vol. I.

KEY TO THE SPECIES.

- A. Shoots herbaceous.
 - B. Fls. carrion-scented..... 1. *herbacea*
 - BB. Fls. not carrion-scented..... 2. *lasioneuron*
- AA. Shoots woody.
 - B. Umbels in axils of normal lvs.
 - C. Foliage completely deciduous.
 - D. Plant not at all glaucous: berries green-black, usually 1-seeded: rootstock short, woody, slow-growing, without long rhizomes: spines long, slender, black, dense below.
 - E. Lvs. orbicular to ovate, not crenulate..... 3. *hispida*
 - EE. Lvs. triangular, ovate, crenulate..... 4. *Sieboldii*
 - DD. Plant, i.e., pedicels, fls., and fr. glaucous: berries 3-seeded: rootstocks long and creeping: spines stout, few, never at nodes.
 - E. Berries blue-black: lvs. broad, ovate: st. green..... 5. *rotundifolia*
 - EE. Berries coral-red.
 - F. Lvs. broad-ovate: st. stout, green..... 6. *excelsa*
 - FF. Lvs. oblong: st. slender, brown..... 7. *Walteri*
 - C. Foliage at least partly evergreen.
 - D. Flowering in the spring: fr. ripe the same season: lvs. partly deciduous in the N.: plants with long-creeping rhizomes.
 - E. Lvs. glaucous, entire-margined: sts. glabrous below, slender, brownish: berries 3-seeded, blue-black..... 8. *glauca*
 - EE. Lvs. green, on vegetative sts. usually hastate and spiny-margined: sts. stout, green, stellate pubescent below: berries 1-seeded, greenish black. 9. *Bona-nox*
 - DD. Flowering in the summer: fr. ripe the next season: lvs. evergreen: underground sts. large, short, fleshy tubers, without long rhizomes.
 - E. Lvs. thin, lanceolate to ovate, slightly glaucous beneath: berries mostly 3-seeded: not a swamp plant..... 10. *lanceolata*

- EE. Lvs. thick, narrow-oblong, green beneath: berries 1-seeded: growing in swamps. 11. *laurifolia*
- BB. Umbels borne on special leafless flowering branches on the old wood: exotic species.
- C. Flowering branch spike-like, with numerous umbels: plant and lvs. spiny..... 12. *aspera*
- CC. Flowering branch short, with 1 or 2 umbels: plant unarmed..... 13. *australis*

1. *herbacea*, Linn. A hardy perennial vine 4-10 ft. high, unarmed: lvs. ovate to lanceolate, acute to cuspidate, obtuse or cordate at base, long-petioled, 7-9-nerved, glabrous and glaucous beneath: umbels 15-80-fld., long-peduncled: fls. carrion-scented: berry bluish black, about $\frac{1}{4}$ in. diam., normally 3-6-seeded. April-June. N. E. U. S. B.M. 1920. B.B. (ed. 2.) 1:527.—This species is undesirable on account of the strong carrion odor of the fls. There are several herbaceous species in N. Amer. and E. Asia, but only this and the following have been intro. to the trade.

2. *lasioneuron*, Hook. (*S. herbacea* var. *inodora*, Hort. *Nemexia herbacea* var. *mexica*, A. Nels). Similar to the above but with the lvs. pulverulent-pubescent beneath: peduncles shorter than the lvs.: fls. not carrion-scented. From Colo. to Man. in the Great Plains and E. Rocky Mts.—Distinguished from the other herbaceous forms by the lack of the carrion odor.

3. *hispida*, Muhl. (*S. Pseudo-china*, Auth., not Linn.). BAMBOO BRIER. Fig. 3623. Rootstock short, woody, slow-growing, never spreading far: sts. clustered, high-climbing, 20-50 ft., green, densely spiny below, unarmed or nearly so above: spines straight, black, slender, usually most numerous at lower nodes, never on upper nodes: lvs. ovate, larger ones heart-shaped, deciduous: peduncle longer than the petiole. Conn. to Minn., south to N. C. and Texas, absent from the coast. B.B. (ed. 2) 1:529. G.F. 5:53 (adapted in Fig. 3623).—This is the only one of the northern species that does not spread rapidly by rootstocks; by proper attention to pruning this species will make an upright hedge-plant of merit.

4. *Sieboldii*, Miq. Closely related to *S. hispida* from which it differs in its weaker habit, more pointed narrower lvs. which in the growing plant are distinctly crenulate: peduncles fewer-fld. and little longer than petioles. Japan and Korea.

3622. *Smilax glauca*. ($\times$ about $\frac{1}{2}$)

5. *rotundifolia*, Linn. HORSE-BRIER. Rootstock scarcely tuberous, long-creeping: sts. stout, green, often angled, never spined at nodes: spines stout, few, black-tipped, straight, often absent on flowering branches: lvs. ovate to orbicular: peduncle scarcely longer than the petiole: berries blue-black, glaucous, less than $\frac{1}{4}$ in., 3-seeded. Nova Scotia to Ill., south to Ga. and Texas.

The common horse-brier of the E. U. S. B.B. (ed. 2) 1:528.—A rank weedy vine with nothing to recommend it for general planting as it spreads rapidly by underground rhizomes.

6. *excelsa*, Linn. Similar to the above in habit: sts. large, angled, with few heavy spines: lvs. heavier and larger: fls. 3-10 in umbel: berries $\frac{1}{3}$ in. diam., coral-red. Persia, S. Eu. to Azores.

3623. *Smilax hispida*. ($\times$ about $\frac{1}{2}$)

7. *Walteri*, Pursh. Underground sts. slender, creeping: st. slender, terete, brownish: armed below with stiff short spines, naked above: lvs. ovate to oblong: umbels few-fld. on short peduncles: berries over $\frac{1}{2}$ in., densely packed in umbels, bright coral-red, white-berried sports are known. Swamps in sandy regions, N. J. to Fla. west to Mississippi River Valley. B.B. (ed. 2) 1:530.—The berries of this species are useful for winter decorations in the holiday season.

8. *glauca*, Walt. CAT-BRIER. Fig. 3622. Underground sts. spiny, tuberous but with long slender rhizomes: sts. slender, brown, spines below, disappearing above, when present always some at nodes: spines stout, recurved: the entire ovate lvs. and often whole plant glaucous: berries 3-seeded, small, peduncles and pedicels slender, longer than petioles. Dry ground, Mass. to Fla. and Texas. B.B. (ed. 2) 1:528. G.F. 5:425 (adapted in Fig. 3622).—Ordinarily counted a bad weed, but perhaps of use in large landscape plantings.

9. *Bona-nôx*, Linn. SAW-BRIER. Underground sts. spiny, often with large tubers, also long, creeping rhizomes: sts. stout, green, densely covered with stiff spines below, lower part of large sts. with a characteristic stiff stellate pubescence not found elsewhere in the genus: lvs. variable, on vegetative branches distinctly hastate or with basal lobes, spiny on margins and midnerve below, smooth and green on both sides; upper lvs. triangular, ovate, thick, fine net-veined: peduncles much longer than petioles, flat, many-fld.: berries 1-seeded, black, not glaucous. Va. and Fla. west to Kans. and N. Mex. B.B. (ed. 2) 1:529.—A rank-growing vine that becomes a bad weed along borders of woods and in half-wooded pastures.

10. *lanceolata*, Linn. FLORIDA SMILAX. Underground sts. short, large, fleshy tubers, densely clustered, suggesting large potatoes: sts. stout, often $\frac{3}{4}$ in. diam., lightly scabrous, glaucous when young, spiny below with stout recurved spines, unarmed above,

climbing to the tops of tall trees often 70–80 ft., much branched above: lvs. thin, evergreen, glaucous beneath, ovate to lanceolate, 2–4 in. long; peduncles shorter than petioles, flowering in summer; young berries remaining over winter and ripening the next summer; berries 3-seeded, $\frac{1}{4}$ in. or more diam. Va. to Fla., Ark., and Texas. July, Aug. B.B. (ed. 2) 1:530.—The best American smilax for cult. as an ornamental vine.

11. *laurifolia*, Linn. FALSE CHINA BRIER. Similar to the above in habit: lvs. narrow, oblong, thick, green on both sides, turning dark brown on wilting; berries smaller, 1-seeded. N. J. south to Fla. and Texas. July, Aug. B.B. (ed. 2) 1:530.—This plant is always found near water, usually associated with *S. Walteri*.

12. *aspera*, Linn. A half-hardy shrub often somewhat scandent, unarmed or with spines: lvs. ovate-deltoid or lanceolate, $1\frac{1}{2}$ –6 in. long, usually blotched with white, 5–9-nerved: fls. white, sweet-scented, in many-fl. umbels; berries $\frac{1}{4}$ in. thick, usually 3-seeded, shining red. S. Eu. to India. Gn. 28, p. 615; 62, p. 397. G. 6:315 (as *S. tamnoides*). Var. *mauritanica*, Gren. & Godr. A more robust form with larger lvs. and fewer spines. Canaries, S. Eu., N. Afr.

13. *australis*, Brown. Sts. terete, robust, rarely spined: lvs. ovate-elliptic, base obtuse, 2–5 in. long, 7-nerved: umbels 1–2 on a short flowering branch without lvs., 15–20-fl. from a globose bracted receptacle: berries about $\frac{1}{2}$ in. diam. Austral.—A tropical plant unsuited to our colder climate.

S. argyræa, Lind. & Rod. Tender foliage plant: st. wiry, slender, armed with short, stout thorns: lvs. lanceolate, becoming 8–10 in. long, dark green, blotched with gray, 3-nerved, short-petioled: fls. and fr. unknown. Bolivia. I.H. 39:152. J.H. III. 46:77. According to G.F. 8:305 the above species is a robust healthy plant doing well in a moderate temperature and quickly forming ornamental specimens. It should be given a rich, fibrous soil and a light and sunny position. It may be prop. by half-ripe cuttings of the side shoots with 2–3 eyes inserted in a moderately warm bed. This may be any one of a number of S. American species. The variegated foliage is found in practically all of the woody plants of this genus, being strongly developed in *S. glauca*, *S. Bona-nox* and *S. lanceolata*.

J. B. NORTON.

SMILAX, FLORISTS'. The smilax of florists is an *Asparagus* (*A. asparagoides*, page 409). It is one of the most popular of all greenhouse vines for use in decoration.

Commercially, smilax is grown in deep solid beds under glass, and the tall growth is tied to strings. These strings are cut for sale. Some growers do not renew their beds of smilax for three or four years. It is doubtless most profitable to replant every year with young stock, grown from seed. It is a heavy feeder. A strong loam with one-fifth half-rotted cow-manure is the best compost for the bed. A light house is not essential. The middle of an equal-span house running north and south is an ideal place for it, if there is height sufficient to run up the strings 7 or 8 feet. Plant as early as possible in July. Many florists who grow a few hundred strings of smilax make the mistake of putting them in a cool-house. It will grow in a temperature of 50°, but not profitably; 60° at night, and even 65°, is the better temperature. The plants should be 8 inches apart in the row and 10 inches between rows. Red-spider attacks the smilax, but daily syringing is a sure preventive. When cutting the strings, avoid picking out one here and there. Begin to cut at one end of the bed, and as much as possible clear off all the strings, because when denuded of so much growth the fleshy roots are liable to rot if over-watered; little water is needed till young growth starts. Care should also be taken in cutting, for many times there will be several young growths a foot or so high that can be saved for a future string, and they may be useless if cut. Good drainage should always be provided.

Smilax for planting in July should be raised from seed sown in February. When 2 or 3 inches high, and showing its character-leaves, it should be potted in 2-inch pots. In May, the plants should go into 3-inch

pots. It is very important that the first growth, which is always weak, should be made in these 3-inch pots; then, when planted out, the first growth in the beds is strong enough to make salable strings. Never neglect tying up smilax as soon as the preceding crop is cut. For this purpose use silkline or similar green twine. Contrary to what is the case with many plants, the hotter smilax is grown the hardier and more durable the leaves, providing it is not cut prematurely.

WILLIAM SCOTT.

SMITHIANTHA (*Smith's flower*, named for Miss Matilda Smith, botanical artist, Kew). A name proposed for the species of *Nægelia* of Regel (which see), a name which had been given four years earlier to a genus of fungi; it is accepted by Fritsch in Engler & Prantl's "Pflanzenfamilien." The names under Smithiantha of the cult. kinds are: *S. cinnabarina*, Kuntze, *S. zebрина*, Kuntze, *S. multiflora*, Fritsch (*S. amabilis*, Kuntze), *S. achimenesoides*, Fritsch.

SMODÍNGIUM (Greek, *indurated mark*; from the callous fr.). *Anacardiaceæ*. Glabrous shrub, allied to *Rhus*: lvs. alternate, long-petioled, trifoliate; the lfts. lanceolate, coarsely serrate: fls. minute, in terminal pubescent panicles, polygamous; calyx 5-toothed, persistent; petals 5, oblong, spreading, deciduous; disk small, annular; stamens 5; ovary free, sessile, 1-celled: fr. compressed, winged-margined, oblique-oblong, vitate on both sides; the shell leathery. One species, *S. Afr. S. argutum*, Mey. Erect or climbing shrub with striate branches: lvs. palmately 3-foliate; lfts. 4–5 x 1 in., lanceolate acuminate, coarsely and sharply toothed: fls. in an ample panicle. S. Afr. R.H. 1908, p. 385. It has been mentioned in cult. in the warm part of the U. S.

SMOKE TREE: *Cotinus Coggynia*.

SMUT. Diseases of many cultivated cereal grasses and other plants caused by the attacks of fungi of the order Ustilaginales. The mycelium sometimes produces swellings on various parts of the host (or attacked plant), the swellings being eventually filled with brownish or blackish spores known as chlamydospores, which emerge, as a fine dust-like powder, when the outer membrane of the tissues bursts or cracks. The chlamydospores produce upon germination a structure known as a promycelium (basidium) which gives rise to lateral or terminal sporidia (basidiospores). The smut on Indian corn may be taken as typical. The disease usually appears first on the leaves, afterward at the junction of leaf-sheath and blade; finally the ear of corn is attacked, and the tassel. On the leaves blisters are found; on the ear, large whitish polished swellings appear. As the spores mature, the swellings become darker in color, and the inclosing membrane finally ruptures, exposing the dark olive-green mass of spores which are 8 to 12 μ (Greek micron) and are beset with fine spines. Unlike most other cereals, maize can be inoculated at any age. Several smuts have been described, viz., loose smut of oats (*Ustilago avenæ*), maize and teosinte smut (*Ustilago zeæ*), loose smut of wheat (*Ustilago tritici*), smut of blue-stem grass (*Sorosporium syntherisma*), rye smut (*Urocystis occulta*), onion smut (*Urocystis cepulæ*), and colchicum smut (*Urocystis colchici*). For the loose smut of oats and wheat, the treatment of the seeds with hot water before planting is efficacious. The corn smut is best controlled by destroying the affected plants before the spores mature. The onion smut is due to infected soil which may be treated with sulfur, or formalin. JOHN W. HARSHBERGER.

SNAKE CUCUMBER: A form of *Cucumis Melo*. S. Courd: *Trichosanthes*. Snakehead: *Chelone*.

SNAKEROOT: Black S.: *Cimicifuga racemosa* and *Sanicula marilandica*. Button S.: *Liatris*. Canadian S.: *Asarum*. Seneca S.: *Polygala Senega*. White S.: *Eupatorium asaroides*.

SNAKE'S BEARD: *Ophiopogon*. **Snake's-Head Iris:** *Hermodydylus*. **Snake's-Head Lily:** *Fritillaria Meleagris*. **Snake's Mouth:** *Pogonia*. **S. Tongue:** *Ophioglossum*.

SNAPDRAGON: *Antirrhinum*.

SNEEZEWEED: *Helenium*. **Sneezeewood:** *Pteroxylon*. **Sneeze-wort:** *Achillea*.

SNOWBALL TREE: *Viburnum Opulus*. **S.-berry:** *Chiococca* and *Chiogenes*; also *Symphoricarpos*. **S.-drop:** *Galanthus*. **S.-flake:** *Leucojum*. **S.-flower:** *Chionanthus*. **S. Glory:** *Chionodoxa*. **S.-on-the-Mountain:** *Euphorbia marginata*. **S. Pear:** *Pyrus nivalis*. **S. Tree:** *Pyrus nivalis*; also *Halesia*. **S. Wreath:** *Nevusia alabamensis*.

SOAP BARK TREE: *Quillaja Saponaria*. **S.-berry:** *Sapindus*. **S.-Bulb:** *Chlorogalum*. **S.-Plant:** *Chlorogalum*. **Soapwort:** *Saponaria officinalis*.

SOBOLÈWSKIA (named for G. Sobolewski, Russian botanist). *Cruciferae*. Erect paniculately branched glabrous annual or biennial herbs, adapted to outdoor use: lvs. long-petioled, rotundate, coarsely crenate: fls. in corymbose racemes, slender-pedicelled, without bracts, white; sepals spreading, uniform at base: silique clavate, compressed or nearly terete, curved, leathery, 1-celled, 1-seeded.—Five species, Asia Minor and the Caucasus region.

clavata, Fenzl. Basal lvs. reniform-cordate, the upper nearly sessile: silique $2\frac{1}{2}$ lines long by $1\frac{1}{4}$ lines wide. May. Asia Minor. F. W. BARCLAY.

SOBRÀLIA (for Fr. Mart. Sobral, a Spanish botanist). *Orchidaceae*. Extremely handsome terrestrial orchids with a very distinct habit, some of them comparing well with cattleyas and lœlias in bloom.

3624. *Sobralia macrantha*. ($\times\frac{1}{4}$)

Leaves with sheathing bases, plicate-venose: fls. membranaceous, few, in short, terminal racemes, or solitary; sepals and petals spreading; labellum convolute around the column, terminal portion large, undulate, often fimbriate, smooth or with longitudinal ridges; column slender; pollinia 8.—About 30 or more species, inhabiting the mountains of Mex. and Trop. Amer. The following account comprises the species

that appear to be in the American trade, but others are to be found in the collections of fanciers. The plants have slender reed-like sts. clothed with lvs. throughout their entire length. The sts. are tufted, forming bushy plants varying in height according to the species. The fls. are among the largest of the orchids, those of *S. macrantha* attaining a diam. of 9 in. across the sepals. They are, however, very transient, fading a few days after opening.

Sobralias are charming orchids, and when room can be given to large plants they well repay the space and care they require. Many of them, to be sure, are very fugacious in their blooming, some lasting only a day, but nearly all of them make up for this by a succession of flowers which is more or less rapid. In size the individual blossoms vary from that of an ordinary *Cattleya labiata* to one scarcely $1\frac{1}{2}$ inches across, and the plants themselves present as great variety, ranging from such as *S. fragrans*, which grows less than a foot high, to that giant of the tribe, *S. Cattleya*, which will reach a height of nearly 10 feet. They also give as much variety in their coloring, ranging from a shade of lavender which is almost a blue through different shades of purple to the rich claret-color of *S. Lowii*, and from yellow to the purest white. Where space for large and bushy plants can be afforded, some of the sobralias will prove most charming plants, having the double advantage of presenting in a well-grown plant not only beautiful blossoms but a subject which is thoroughly attractive as a foliage plant. They also have the added advantage of being, in most instances, of rather easy culture. Given a suitable soil and a liberal supply of water they are almost sure to grow and bloom, although they will do better if they are given their time for rest, when less water is allowed without permitting the material about the roots ever to become quite dry. (F. J. Le-Moyne.)

INDEX.

alba, 5, 7.	Holfordii, 8.	macrantha, 5.
albida, 5.	Kienastiana, 5.	nana, 5.
Brandtiae, 6.	leucoxantha, 1.	superba, 3.
Cattleya, 9.	lilacina, 2.	virginialis, 2.
Fenzliana, 7.	Lowii, 10.	xantholeuca, 3.
fragrans, 4.		

A. Fls. white (see also Nos. 5 and 7).

B. Lip shorter than sepals, orange, center lined brown.

1. **leucoxantha**, Reichb. f. Sts. tufted, 3 ft. high, spotted: lvs. 4-6 in. long, lanceolate, acuminate: fls. 6-7 in. across; sepals linear-lanceolate, spreading and recurved, white; petals shorter, oblong, undulate above, also pure white; labellum with a ventricose tube; limb large, circular, notched in front and the margin irregularly lobulate and wavy, throat golden yellow, with a few brownish stripes. Aug. Costa Rica. B.M. 7058. R.B. 23:205. J.H. III. 33:77; 46:331.

BB. Lip nearly as long as sepals, yellow, center marked with orange.

2. **virginialis**, Cogn. Sts. up to 3 ft. tall: lvs. coriaceous, broadly lanceolate, 5-6 in. long, $1\frac{1}{2}$ in. broad: fls. solitary, sessile, white except the yellow disk and throat; sepals revolute at apex, $3\frac{1}{2}$ in. long; petals a little shorter than sepals, undulate; lip as long as petals, strongly undulate crisped. Colombia. C.O. 3. Var. **lilacina**, Cogn., has the lip tinted lilac. C.O. 3a.

AA. Fls. yellow.

B. Lip crisped and undulate on margin; fls. 5 in. or more across.

3. **xantholeuca**, Reichb. f. Sts. about 2 ft. high, tufted: lvs. spreading and drooping, lanceolate, 6-7 in. long, with speckled sheaths: fls. solitary, lemon-yellow, with a deeper shade on the lip; sepals linear-lanceolate, spreading and recurved; petals similar but shorter; blade of the labellum orbicular, crisp, and undulate,

margin crenate. Guatemala. B.M. 7332. R.H. 1890: 12. G.C. III. 5:9. Gn. 22: 508. C.O. 2.—A species with fls. about as large as *S. macrantha*, but plants of more compact habit. Var. *superba*, Hort. Fls. deeply shaded with deep cream-yellow; throat marked with orange-brown.

BB. Lip fimbriate on margin; fls. less than 3 in. across.

4. *fragens*, Lindl. A small species with sts. about 1 ft. high: lvs. 1 or 2, oblong-lanceolate, 4-5 in. long: fls. 2-3 on a long peduncle, about 2 in. long, pale sulfur-yellow; sepals oblong, spreading; petals similar but erect; middle lobe of the labellum fimbriate on the margin and having many fimbriated crests. Colombia. B.M. 4882.—One of the smallest of the genus.

AAA. Fls. chiefly purple or rose.

5. *macrantha*, Lindl. Fig. 3624. Sts. tufted, reed-like, 4-7 ft. high, leafy all the way up: lvs. broadly lanceolate to oblong-lanceolate, long-pointed, 8-10 in. long: fls. several at the ends of the sts., rose-purple, with the front of the labellum deep purple; sepals linear-oblong, 4½ in. long, reflexed and twisted; petals broader, oblong, wavy above; labellum 5 in. long, with the expanded portion almost circular, 3 in. across and 2-lobed at the apex, very wavy; tube long, whitish within, with a yellow stain in the throat and several thin yellow ridges. May-July. Mex. and Guatemala. B.M. 4446. F.S. 7:669. P.M. 14:241 (var). G.M. 31:559. C.O. 1. O. 3:75. Var. *Kienastiana*, Hort., (var. *alba*) has white fls. G.C. III. 48:182. Var. *albida*, Hort. Fls. very large, creamy white. Var. *nana*, Hort. Fls. smaller than type; lip dark violet-purple.

6. *Brändtiae*, Kränzl. Sts. 3 ft. high: lvs. lanceolate, acuminate, 8 in. long: fls. purple-rose, paler outside, with the labellum darker and having a yellow disk; sepals linear; petals twice as wide; middle lobe of the labellum very broad, divided into 2 diverging, rather acute lobes; anther-bed with a long recurved horn on each side. Resembles a medium-sized *S. macrantha*, distinguished by the long horns of the column, and black spots (not hairs) on the lf.-sheaths. S. Amer.

7. *Fenzliana*, Reichb. f. Sts. slender: sheaths blackish, asperulate: lvs. oblong, acutish: fls. rose-colored; sepals oblong, acute; petals obovate-cuneate, three-fourths as long as the sepals; labellum spreading, front portion ovate, notched, crenulate; horns of the column equaling the anther. Nicaragua. Var. *alba*, Hort., has pure white fls.

8. *Hölfordii*, Sander. Plants of dwarf habit: fls. rose-carmine, deeper in the lip, shading to whitish in the throat. Habitat not stated by Sander.

9. *Cattleya*, Reichb. f. St. stout: lvs. oblong, acuminate, plaited, bearing several lateral clusters of strong, thick fls. of a firm fleshy texture, with purplish brown sepals and petals and a purplish lip, with a white column and 3 yellow lines over the center of the lip. Colombia.

10. *Löwii*, Rolfe. An imperfectly known species intro. about 1892 from Colombia. It grows about 1½ ft. high and has fls. of a bright uniform purple.

S. Amesiae—*S. Wilsonii* × *S. xantholeuca*. G.C. III. 40:suppl. Aug. 25.—*S. Amesiana*—*S. Wilsonii* × *S. xantholeuca*. G. 31:581.—*S. blanda*, Kränzl. Fls. 6 in. across, white, except throat and middle portion of disk of lip, which are golden yellow. Hab. (?)—*S. Charlesworthii*, Hort. Fls. rich rose-purple, with broad purple band around lip and bright yellow crest. Colombia.—*S. Cliftoniae*, a dwarf, white-fld. species, said to come from Ecuador. G.M. 53: 325. J.H. III. 53:75; 63:3 (both as *S. Hölfordii*).—*S. Cölmarii*—*S. xantholeuca* × *S. Veitchii*.—*S. Elizabethae*—*S. Liliastrium*.—*S. Lanthoinei*—*S. Ruckeri*.—*S. Liliastrium*, Lindl. Fls. large, white, yellow-veined. Guiana, Brazil.—*S. Lucasiana*, Hort. Fls. large; sepals and petals white; lip soft rose-purple, throat yellow. Trop. Amer.—*S. luminosa*—*S. Hölfordii* × *S. Wilsonii*.—*S. Malmquistiana*, Schlecht. Fls. pale rose, with orange-yellow blotch on lip. Colombia. O. 1911:59, desc.—*S. murdibilis*—*S. Veitchii* × *S. macrantha* Kienastiana.—*S. Ruckeri*, Lind. & Reichb. f. Sepals and petals pale rose-purple; lip with a white base, marked with a yellow band, the front of lip dark rose-purple. Colombia. G.C. III.

30:67. J.H. III. 48:531.—*S. schoenbrunnensis*—*S. xantholeuca* var. *superba* × *S. macrantha*.—*S. sessilis*, Lindl. Sheaths and under surface of lvs. black-pubescent: lvs. sessile, oblong-lanceolate: fls. sessile, rose, the lip darker. Guiana. B.R. 27:17. J.F. 1:104.—*S. Siebertiana*—*S. macrantha* Kienastiana × *S. Hodgkinsonii*.—*S. valida*, Rolfe. Fls. about 2 in. long, fragrant, whitish yellow, with deeper yellow band on lip, becoming deep orange in front. Panama.—*S. Veitchii*, Hort.—*S. macrantha* × *S. xantholeuca*. Sepals oblong, somewhat undulate, white, lightly tinted rose-lilac; petals oval-oblong, undulate, white, tinted rose; lip ample, the limb strongly tinted with lilac-violet, the throat orange, the margin strongly undulate-crested. J.H. III. 63:171. C.O. Hyb. 1.—*S. Wiganiae*—*S. macrantha* × *S. xantholeuca*. G.M. 45:441.—*S. Wilsonii*, Rolfe. Fls. large, white, shaded with rose and spotted with purple.

GEORGE V. NASH.†

SOCRATEA (named after the philosopher Socrates). *Palmaceæ*. Treated by Drude, in Engler & Prantl's "Pflanzenfamilien," vol. 2, part 3, page 60, as a subgenus of *Iriarte*, the subgenus characterized by the numerous stamens, the branches of the raphe which rise from the base and are united, running up to the micropyle which is at the apex of the seed.

Forgetiana, Hort. (*Ceratolobus Forgetiana*, Hort.). Lvs. rich green, at first entire and broadly rounded, later pinnate with the terminal lft. much larger than the others. Peru. G.C. III. 51:suppl. May 25, p. xv.; 53:286. G.M. 55:636. Gt. 61, p. 391.

SOIL. The soil is a superficial covering of the earth's crust, more or less well adapted to the growth of plants. It is usually only a few inches thick. Below this is a subsoil often differing, especially in humid climates, from the soil proper in color, texture, or chemical composition. A very striking definition has been suggested by Sir John B. Lawes, who considered the soil to be rotten subsoil, and the subsoil rotting rock. The term soil is occasionally used in a more comprehensive way to include both the soil and the subsoil.

The soil adapted to the growth of the higher plants consists of fragments of rocks or minerals, organic matter, soil solution, and a soil atmosphere. The mineral fragments vary in size from the finest clay particles to gravel and even boulders. The organic matter is derived from low organisms, from previous vegetation, or from growing plants; as also from stable manure, and occasionally fish or animal matter added to the soil by man. The soil solution consists of water carrying dissolved substances derived from the soil grains and from the organic matter, as well as from fertilizing materials artificially applied, and constitutes a nutrient solution from which the plant derives its mineral constituents. The soil atmosphere differs from the ordinary atmosphere above the soil in being richer in carbon dioxide and nitrogen, and containing more water vapor and less oxygen.

In origin there are two main classes of soils: sedimentary soils, formed by the disintegration and decomposition of rocks in place; and transported soils, including those of alluvial, glacial, and æolian origin. The word alluvial is here used to include all water-transported material; the term is, however, frequently used in a more specific sense to indicate the recent flood deposit of rivers.

Soils are classified according to their origin and their mechanical and chemical composition and properties. Genetically, they are classified according to the rock from which they are derived, as granite soil, limestone; or according to the manner of their origin, as alluvial, lacustrine, or drift. Mechanically, they are classified broadly into stony, gravelly, sandy, sandy loam, loam, clay loam, clay, adobe, black-waxy, or according to some other physical property; chemically, into calcareous, humus, alkali, and according to other striking chemical features. In the soil survey of the United States Department of Agriculture a local name is adopted for each type under which the specific characters are given; examples of this are Hartford sandy loam, Norfolk sand, San Joaquin adobe.

The physical properties of soils concern the size and

arrangement of the particles, and the relation of these to each other and to the organic matter; also the soil atmosphere, the soil moisture, and the physical forces of heat and gravitation. In these there is an intimate relation with physiography or the form and exposure of the surface of the land, as well as to climatology.

There are, undoubtedly, constant physical changes going on in the soil, as well as chemical changes, which have much to do with the best development of vegetation. The soil-moisture may be looked upon as a nutrient solution, dissolving its material from the difficultly soluble compounds in the soil and from fertilizers artificially applied. The amount of substances in solution varies with the moisture content and with the way moisture is supplied to the soil. The dissolved substances, naturally present in the soil or derived from fertilizers, influence the solubility of the soil components, rendering them more or less soluble according to their nature and existing conditions. It is probable that there is a normal weathering of the soil material which produces a certain concentration in the soil solution which will be maintained on the gradual withdrawal of nutrient material by the plant. However, this natural weathering is often not sufficient in amount to produce the yield and quality of crops desired, and this may be increased by methods of cultivation and fertilization so that crops may annually remove larger quantities of nutrient substances without any particular exhaustion to the soil.

It is certain that these nutrient materials do not accumulate to any considerable extent in soils in humid countries, as they are liable to be leached away and also to recombine, forming difficultly soluble compounds with the material of the soil-grains. A soil is in good heart or good condition when the physical conditions, such as the water-supply, soil atmosphere, and temperature relations, are favorable, and when the weathering of the material is sufficient to furnish an abundant and constant nutrient solution in the soil moisture.

One of the most potent agents in the weathering of soils is the organic material contained. This is unquestionably due largely to the amount of carbon dioxide formed, which renders many of the nutrient matters

The influence of fertilizers is therefore twofold: the direct addition of plant-food for the immediate use of plants, and the action of the fertilizing components upon the solubility of the otherwise difficultly soluble compounds in the soil. There are other offices which are very strikingly shown in the case of lime. This substance, when in the form of either caustic or slaked lime, corrects the acidity which is very often present in soils. It changes the structure of soils. It renders some of the soil components much more soluble, especially when the lime is in the form of the sulfate or gypsum, and it has undoubtedly a physiological rôle which enables the plant to assimilate larger quantities of other nutrient matters even in amounts which would be detrimental if the lime-salt were not present in excess.

The principal objects of the cultivation of the soil are to secure proper aëration, to conserve the moisture supply, and to improve the drainage. The irrigation and artificial drainage of soils are treated elsewhere.

The physical properties of texture and structure, that is, the size and arrangement of the soil-grains, have a greater practical importance with field crops and the relation of crops to soil under extensive cultivation than upon horticultural crops either in the field or greenhouse, where intensive methods are used. Particularly in the eastern states, where the natural rainfall is relied upon for the water supply, these physical properties have great influence in determining the relation of crops to soils. This is due in large part to the influence of the physical properties upon the water supply, and the commercial values of many soils are dependent largely upon this one condition. This is notably the case with the early truck crops, with corn, wheat, and grass lands, and with special products such as celery, cranberries, and other horticultural crops. With intensive cultivation, however, the flavor, appearance, texture, and general quality of the crop assume greater commercial importance, and even with intensive methods these are largely influenced by the character of the soil. This is shown in a striking manner in the localization of certain interests, even under the most intensive system of agriculture, such as the production of the fine lettuce around Boston, of the carnations, violets, tomatoes, and roses in other districts. With the present specialization in these lines, it is not only necessary that one should have a knowledge of the methods of cultivation, but should have the proper soil conditions as well as suitable climatic conditions; and to such an extent has this specialization been carried that different varieties of roses, for example, are best grown in different localities where the soils are slightly different. These matters must be realized by the horticulturist in order to attain the highest degree of success in any particular undertaking.

MILTON WHITNEY.

Soils for potting.

Strictly speaking, there are but two distinct kinds of soils, though there are several modifications or physical differences in both. These are mineral soils and organic soils or peat. Peat is formed in temperate climates by the accumulation of vegetable matter in swamps, or in some parts of the world under peculiar atmospheric conditions (see *Peat*). Mineral soils, which cover the greater portion of the earth's surface, are formed by the disintegration of rocks and stones through the agency of water, frost, or the atmosphere. Peaty soils are composed almost entirely of vegetable matter, with but little mineral matter. Mineral soils are just the reverse. The physical differences in peat are practically reduced to two, viz., the absence or presence of fiber. The physical differences in mineral soils vary considerably from almost pure clay to almost pure sand; indeed, the mechanical (or physical) analysis of mineral soils is based largely upon the proportions of clay and sand.

3625. How the gardener makes his soil, by letting it decay in piles. The larger pile is composed of sods.

much more soluble. Moreover, the organic matter forms a culture medium for bacteria, ferments, and the various organized and unorganized agents which assist in breaking down the organic material, and facilitate as well the weathering of the other soil components. Soils in general have remarkable power of absorbing on the surface of the soil-grains vast quantities of carbon dioxide, ammonia, and other gases, and of other nutrient materials, which, while soluble and actually dissolved, do not readily diffuse out into the solution between the soil-grains.

The composition of soils can be still further known by chemical analysis, but to the average gardener this is not necessary. Moreover, it is an operation of great nicety and one that requires an experienced chemist to perform. The chemical constituents which plants derive from the soil are present in most soils, though in varying degree, but they are sure to be present in ample quantity in the potting soil selected by an experienced gardener. The air and water may furnish as much as 98 per cent of the material with which the plant body is built up in some cases, and only the remaining 2 per cent be strictly derived from the soil. Three important nutrient elements are nitrogen, phosphoric acid, and potash. Nitrogen composes four-fifths of the atmosphere and the soil absorbs it chemically through the action of bacteria when the soil is in good physical condition. Hence the importance of remembering always that air in the soil is as important as water. Sorauer, in his "Physiology of Plants," page 56, says: "The ideal condition of a soil is one in which it resembles a sponge, and in which it will retain the greatest amount of nutritive substances and water without losing its capacity for absorbing air."

The capacity of soils to retain moisture varies considerably. A clay loam is more retentive of moisture than a sandy loam. The experienced gardener therefore selects a clay loam for his strong-rooting, large-leaved tropical plants, because transpiration is so much greater in these plants. For a general collection of greenhouse and small-growing tropical plants he selects a good loam. For cacti, agaves, and other succulent plants which will not take as much water at all seasons as other plants, he selects a sandy loam. For ferns, most of the Ericaceae and Gesneraceae, he selects peat; while for nepenthes, orchids, bromeliads, and the epiphytic aroids he selects fern or kalmia root. Other materials which a gardener should always have on hand when he has a large and varied collection of plants are: leaf-mold, which is made by collecting leaves and storing for at least two years, turning them over occasionally to facilitate decay; living or fresh sphagnum moss; sand; charcoal, and some convenient manures, such as pulverized sheep-manure and bone-meal.

Growing plants in pots is very different from growing them in borders or the open ground. The experienced gardener digs the turf only from good pasture or meadow land, so that it shall be full of the fibrous roots of the grass. But before using the turf for potting it should be placed in square piles, turf downward, for at least six months in order to kill the grass and all vegetable life. Fern root should also be collected and stored the same length of time in order to kill out the ferns. (Fig. 3625.) Raw and very coarse soils are usually sifted before being used for most greenhouse plants. Shallow sieves are used for this purpose. (Fig. 3626.)

Except for sowing seeds and for potting seedlings and freshly rooted cuttings, thoroughly decayed and homogeneous soils should not be sifted, but should be broken into small lumps, as the small lumps assist materially in aerating the soil. If the soil is sifted too much it becomes very fine, packs close and allows too little aeration. Leaf-mold is decayed vegetable matter, or humus. It may have little manurial value, but is used by gardeners to make soils "light" or spongy. For most young plants a good proportion added to the soil is excellent as it encourages root-growth.

Sand is the best medium for rooting cuttings of the larger number of plants. It is also added to soils to increase their porosity, especially when potting very young plants. Silver sand is best.

In potting plants, experienced gardeners make potting mixtures or add a variety of materials to the soil to suit the requirements of different plants. For young seedlings or for freshly rooted cuttings, the compost should be of a light and porous nature, but as plants

increase in size and vigor a heavier and richer mixture is usually given, that is, if plants are to be grown on as specimens; but the proportion of nutrient substances used in a potting mixture should be determined by the vigor of the plants. It is always better to use too little plant-food than too much; if too much is used it often becomes available faster than the roots of plants can

3626. Sieves for sifting or riddling soils.

absorb it, often with fatal results. Many amateur plant-growers in their over-anxiety to grow fine plants make this fatal mistake.

In most gardens the greenhouse space is limited, and a gardener cannot always develop his plants to their fullest capacity or he has to reduce his variety and numbers. This, then, determines in the mind of an experienced gardener the composition of his potting mixtures. His aim should be to grow the finest possible specimens in the smallest possible pots and space.

EDWARD J. CANNING.

SOILS, STERILIZING. Greenhouse and plant-bed soils are specially liable to infection by disease organisms, as they are intensively cropped and not exposed to the action of frost and weather. Careful growers now resort to methods of artificial sterilization.

In practice, the sterilizing is accomplished either by heat applied by live steam, or by a chemical process employing a formalin drench. In either case, the work must be thoroughly performed if satisfactory results are to be expected; it will be required at least as often as every other year, and the situation is safer if sterilizing is practised annually.

Steam sterilizing is of two methods: by buried perforated pipes, and by a pan inverted over the soil and under which the steam may be conveyed. The latter is probably preferable in most cases. In either case, live steam should be applied for an hour or more.

"The perforated pipe method appears to consist, at its best," according to Selby and Humbert in Circular No. 151 of the Ohio Experiment Station, "in a system or set of perforated pipes, with crosshead and high-pressure boiler connection. These pipes are connected and buried in the soil of the bed, either with or without partial banking up of the soil; the surface of the bed is then covered with canvas or other covering and the steam passed into the system for such a period as is required to heat the soil to the necessary temperature. This temperature for best results is 180° to 212° F. maintained for a period of an hour or more. The time required to reach this temperature will vary with the boiler area, the pressure and other steam and soil factors. The length of pipes of the system will be adapted to the beds, being one-half or one-third the total length of large beds. Generally, 1½-inch pipe is used with ⅛-inch holes bored in a straight line about 1 foot apart. These pipes are buried in the beds 12 to 16 inches apart."

For the inverted pan method, "The apparatus consists," according to W. W. Gilbert, "of a galvanized iron pan, 6 inches deep and 6 by 10 feet in size, which is inverted over the soil to be sterilized and the steam admitted under pressure. The pan is supplied with steam hose connections, has sharp edges, which are forced into the soil on all sides to prevent the escape of steam, and is fitted with handles for moving it from place to place, the weight of the entire pan being not over 400 pounds."

Remarking on the formaldehyde or formalin drench method, Selby and Humbert say that "Soils to be treated by any method of sterilization should be prepared as for use by addition of manure so that the latter is incorporated with the soil before treatment. The soil after spading or plowing is ready for treatment, whether by steaming or drenching. For the work of drenching it is rather difficult to make exact estimates as to cost of appliances, as well as labor outlay, since the appliances are the usual watering devices of greenhouses or coldframes, and the labor will be somewhat variable according to the effectiveness of these devices. The appliances used may be extremely various, though usually some form of sprinkling-can, a force pump with hose and nozzles or application through the overhead Skinner watering system. For outside beds the hose and force pump offer a convenient method. The best strength appears to be three to three and one-half pints or pounds to each fifty gallons of drench applied at the rate of seven-eighths to one gallon to the square foot of surface."

SOLÁNDRA (named for Daniel C. Solander, a Swedish naturalist and traveler, 1736-1786). *Solanaceæ*. Very tall glabrous woody showy-flowered vines suitable for the warmhouse, and grown in the open in the warmest parts of the United States.

Leaves entire, leathery, shiny; fls. very large, white; the pedicels solitary and thick; calyx long-tubular, 2-5-cleft at the top; corolla funnelform, the tube cylindrical, the throat oblique and broad-campanulate, lobes broad; stamens 5; ovary 2-celled: berry globose, pulpy. —About 4 species, Trop. Amer.

Solandas are attractive plants and their needs are simple. A warm greenhouse—one in which the temperature is never allowed to fall below 50°—will suit them very well in the eastern states. The plants would

probably do well outdoors in Florida and the far South. They like plenty of light and sunshine at all seasons of the year, and water should be given freely from early autumn till the latter part of spring, as they make their growth and bloom during that period. In summer, when the wood is ripening, a dry state is preferable for them. The soil that gives the most satisfactory results is a good, somewhat sandy loam. It is unwise to disturb the roots of established plants more frequently than is necessary. The chief point in growing solandas is to

obtain short, sturdy branches, for those of rank growth seldom or never develop flowers; for this reason the use of rich soils and strong fertilizers should be avoided always. Propagated by cuttings of firm young shoots taken with a heel and placed in slight bottom heat. *S. grandiflora* is perhaps the best. The flowers do not last more than four or five days. They are of a pretty greenish white color when they first open and turn slowly to a rich brownish yellow. (Michael Barker.)

A. Plant about 2 ft. high, with trailing branches.

longiflora, Tussac (*S. lævis*, Hook.). Lvs. oblong-ovate or obovate, acute; petioles purplish; fls. fragrant; corolla usually 1 ft. long, 3 times as long as the calyx, contracted at the throat, white or yellowish. B.M. 4345.

AA. Plant becoming 12-20 ft. high.

grandiflora, Sw. Fig. 3627. Lvs. obovate-oblong, acute, glabrous, thick; fls. fragrant; corolla twice as long as the calyx, not contracted at the throat, white or somewhat yellowish. B.M. 1874. G.C. III. 21:273. Gn. 53:214. J.H. III. 34:123.

guttata, Don. Shrub about 12 ft. high, erect, branched; lvs. alternate, petioled, elliptic-oblong, acute or very short-acuminate, entire, rather glabrous above, paler and copiously pubescent beneath, base broadened, rounded, 3-6 x 2-3 in.: fls. terminal, solitary, fragrant, ochre-yellow, large; calyx tubular, pubescent, 3 in. long; corolla funnelform, 9 in. long, 5-lobed, lobes crenate and undulate, 5 purple-brown ridges at the throat. Mex. B.R. 1551.

Härtwegii, N. E. Br. Branched shrub: lvs. alternate, glabrous, elliptical, acute, short-acuminate or obtuse, base acute; fls. solitary, terminal, yellow, 6-8 in. across; calyx 5-angled, unequally 3-4-lobed; corolla glabrous, tube 5-ribbed, ribs green outside, brownish purple inside, lobes 5, more or less crisped and turned back. Mex. G.C. III. 49:383. F. TRACY HUBBARD.†

SOLÁNUM (Latin, *solamen*, solace or quieting). *Solanaceæ*. NIGHTSHADE. A vast group of temperate and tropical herbs, shrubs and even trees, comparatively poorly represented in temperate North America, of various horticultural adaptabilities, comprising ornamental subjects and also the potato, tomato, eggplant, ground cherry or physalis, red pepper or capsicum; also medicinal plants.

Leaves alternate: infl. mostly sympodial and therefore superaxillary or opposite the lvs.: corolla gamopetalous and rotate or shallow-campanulate, plaited in the bud, the limb angled or shallow-lobed; stamens usually 5, inserted on the throat of the corolla, the anthers narrower or elongated and connivent and mostly opening by an apical pore or slit; ovary usually 2-loculed, ripening into a berry which is sometimes inclosed in the persistent calyx; fls. white, purple or yellow.—Dunal, the latest monographer (DC. Prodr. 13, pt. 1), in 1852, recognized 901 species, and many species have been discovered since that time, the number now being estimated at about 1,200. Many new species have recently been described by Bitter in various volumes of Fedde, Rep. Nov. Sp. Reg. Veget. The genus finds its greatest extension in Trop. Amer. Of the vast number of species, barely 25 are of much account horticulturally, and half that number will comprise all the species that are popularly well known. One of these is the potato, *Solanum tuberosum*, one of the leading food plants of the human race. The genus seems to abound in plants with toxic properties, although its bad reputation in this respect is probably exaggerated. The species are herbs in temperate climates, but in warm countries many of them are shrubby and some are small trees. Many of them are climbers. It is impracticable to distribute the few cult. species into the various botanical groups of a great genus, and the following species are therefore assembled mainly on a

3627. *Solandra grandiflora*. (X 1/4)

horticultural plan. See Baker, Journ. Linn. Soc. 21, for account of the tuberiferous solanums. Other important papers on the tuberous species are Berthault, *Recherches botaniques sur les variétés cultivées du Solanum tuberosum* et les espèces sauvages de Solanum tuberifères voisins, Ann. Sci. Agron. Ser. III. 6th année 1911; Sutton, in Journ. Linn. Soc. Bot. 38:1909; Wittmack, Bericht Deutsch.-Bot. Gesellschaft 27:28, 1909, and Landwirtschaftliche Jahrbücher Zeitschrift 38: suppl. 5, 1909; Heckel, sur les Origines de la Pomme de Terre Cultivée, etc. Ann. de la Faculté des Sci. de Marseille 16:1906; Ballivian & Tovar, Noticia Historica y Clasificación de la Papa de Bolivia. 1914.

3628. Tuber of potato.—*Solanum tuberosum*. ($\times \frac{1}{2}$)

and probably also W. Texas, but apparently very infrequent.—The species has nothing to do with the potato and is much less frequent than the following.

4. *demissum*, Lindl. Sts., both surfaces of the lvs., pedicels, and calyx pubescent with flattened hairs: lvs. 4–6 in. long with 2–3 pairs of mostly oval lateral lfts., the upper pair sometimes decurrent with the rachis, terminal lfts. much larger than the lateral ones, obovate or oval, interspersed lfts. few: fls. appearing when the plant is quite small and continuing to bloom for some time; calyx-lobes shorter than or only equaling the tube, ovate, slightly acuminate; corolla violet, $\frac{1}{2}$ – $\frac{3}{4}$ in. diam.: fr. ovoid or globose-ovoid: tubers an inch or more in diam. New Mex., Ariz. and N. Mex.—Apparently not infrequent.

5. *edinense*, Berthault. Sts. angled, rather strongly villous: lvs. unequally pinnate, the segms. unequal at the base, pubescent on both surfaces: calyx rather densely hairy with flattened hairs; corolla purple: fr. globose or slightly ovoid.—The tubers are white in the skin and flesh and after 20 years of garden cult. are reported to average $1\frac{1}{2}$ in. diam. For several years this species was confused with *S. etuberosum* which apparently does not produce tubers, and from which it may easily be distinguished by the hairy calyx and larger lf.-segms. Original locality probably Chile.

6. *etuberosum*, Lindl. Sts. 1–2 ft. high, angled: lvs. rather densely short-pubescent: pedicels about $\frac{1}{2}$ in. long, glabrous but peduncle pubescent: calyx-lobes nearly or quite glabrous, short-ovate, and abruptly contracted to a short acute point; corolla large, deep purple with a yellowish center. Not known to produce tubers, but may be multiplied by dividing its stout underground sts. and also grown from seed. Chile. B.R. 1712.

BB. Corolla deeply lobed.

7. *Jamesii*, Torr. Low and slender, 12–18 in. tall under cult., the small angular branches glabrous or soon becoming so: lvs. oblong in general outline, the rachis narrow-winged, the lfts. 5–9, with no interposed small ones, small and lanceolate-oblong in shape: fls. small, white, the corolla deeply cleft and the anthers large and prominent: tubers few, globular, hard, 1 in. or less in diam., withstanding frost. Mountains of Colo., New Mex., Ariz., and Mex. B.M. 6766.—Sometimes cult. as a curiosity. The tubers do not appear to be eaten.

8. *Commerstonii*, Dun. Sts. angled, sparingly pubescent or glabrate: lvs. pubescent, strongly so on the lower surface, or sometimes nearly glabrous, mostly 4–8 in. long with 2–4 pairs of lfts., the lfts. oval or slightly

A. Species bearing underground tubers (except No. 6): lvs. pinnate.

B. Corolla not deeply lobed.

1. *tuberosum*, Linn. POTATO. Figs. 3628, also 3152, 3153, Vol. V. Low, weak-stemmed, much-branched perennial with tender, herbaceous tops, and perpetuating itself asexually by means of thickened or tuberous underground sts., glabrous or pubescent-hirsute: lvs. unequally pinnate, the 5–9 oblong-ovate lfts. interposed with much smaller ones: fls. variable in color, white passing through various tints and shades of purple, violet, and blue, in long-stemmed dichotomous clusters: fr. a globular berry $\frac{1}{2}$ –1 in. or more in diam., usually through lack of viable pollen not produced in the highly developed modern varieties except in favored localities and in the case of certain varieties, but fruiting abundantly in S. Chile and in Peru. Temp. Andes of Peru and Bolivia. See *Potato*.

2. *Maglia*, Schlecht. DARWIN POTATO. Rough-hirsute branched perennial, with angled more or less winged sts. at least near the insertion of the lvs.: lvs. unequally pinnate, the terminal lft. 4 in. long, the lateral ones 2–3 pairs, elliptical, unequal at the base, acute at the apex, the interposed lfts. very small or sometimes wanting entirely: fls. in dichotomous clusters, the pedicels articulate about the middle; calyx hirsute, the lobes abruptly narrowed to a linear-acuminate point; corolla pure white, slightly lobed, the lobes acute. Infrequent along the Chilean coast from the vicinity of Valparaiso southward, and occasionally on the islands as far as the Chonos Archipelago. B.M. 6756.—Tubers gathered by the writer were about 4 in. long, dark purple, both in the skin and flesh. Apparently very difficult to hybridize with *S. tuberosum*. It was at one time considered by some to be the original of the potato. Darwin describes the plant in his "Naturalist's Voyage."

3. *Fendleri*, Gray (*S. tuberosum* var. *boreale*, Gray). Herbaceous perennial with st. about 18 in. high, angled, and foliage somewhat resembling the common potato:

ovate, usually confluent with the rachis, obtuse at the apex, $\frac{1}{2}$ – $1\frac{1}{2}$ in. long, the terminal one somewhat larger, the upper lateral pair sometimes more or less adnate with the terminal, interspersed lfts. very few or none: calyx slightly pubescent, the lobes ovate-acute, about a line long; corolla white or pale violet, rather deeply lobed, pubescent on the outer surface, rather strongly so toward the apex of the lobes. E. Argentina and Uruguay, usually in moist situations. Trans. Hort. Soc., vol. 5: t. 10.—Of no value in the improvement of the common potato. See suppl. list, p. 3186.

AA. *Species grown for the edible frs.: lvs. simple.*

9. *nigrum*, Linn. BLACK NIGHTSHADE. MORELLA of the French. Low unarmed herbaceous annual or suffrutescent in warm climates, glabrous or the young parts sometimes sparingly pubescent: lvs. simple, ovate,

stand considerable frost. In warm countries, according to Vilmorin, the lvs. are sometimes eaten as spinach is, "and apparently without any injurious result, although the plant belongs to the dangerous family of the Solanaceae." The species is extremely variable, and much difference of opinion exists in regard to the poisonous qualities of the berries. Possibly differences exist in this respect in different forms but not correlated with characters recognizable by the systematist. Var. *guineense*, Linn., with scarcely angled to angular smooth st., broadly ovate lvs. glabrous above and glabrous or sparingly pilose below, deeply lobed calyx and relatively large fr., is the "garden huckleberry" (Fig. 3629). This form is cult. to some extent in some sections and the fr. used for pies and preserves. Another form, *S. Burbankii*, bitter, with foliage rather dark green above, and erect or ascending peduncles, is stated by the originator to be a hybrid between the "garden huckleberry" and *S. villosum* of the Pacific coast. In some characters it appears to be intermediate between its supposed parents, and it is used as is the former.

10. *muricatum*, Ait. (*S. guatemalense*, Hort.). PEPINO. MELON PEAR. MELON SHRUB. Fig. 3629. An erect spineless bushy herb or subshrub 2–3 ft. high, the branches often with rough warty excrescences, and usually glabrous or nearly so: lvs. entire or with slightly undulate margins, rarely ternate, oblong-lanceolate, or ovate, tapering to the more or less margined petiole and also toward the more or less obtuse or sometimes acute apex, the surface sparingly soft-pubescent: fls. in a long-stalked cluster, rather small, the corolla bright blue, deeply 5-lobed, puberulent on the outer surface, inclined or nodding: fr. ovoid or egg-shaped, long-stalked, drooping, yellow overlaid with splashes of violet-purple, 4–6 in. long when cult., flesh yellow and seedless under cult. Said to be a native of Peru and cult. in other parts of Trop. Amer. at temperate elevations. G.F. 5:173. G.C. III. 3:309.—This plant attracted some attention in this country about 25 years ago. It appears to have been intro. into the U. S. from Guatemala in 1882 by Gustav Eisen. A full review of the history and botany was made in Cornell Exp. Bull. No. 37 (1891). The fr. is aromatic, tender, and juicy, and in taste suggests an acid eggplant. In a drawer or box, the fr. may be kept till midwinter. In the N. the seasons are too short to allow the fr. to mature in the open, unless the plants are started very early. The pepino is properly a cool-season plant, and when grown in pots in a cool or intermediate house will set its frs. freely. It is readily prop. by means of cuttings of the growing shoots. The plant will withstand a little frost.

11. *Melöngena*, Linn. (*S. insanum*, Linn.). Erect and much-branched herb or subshrub, 2–3 ft. tall, woolly or scurfy, spiny: lvs. large and heavy, ovate or oblong-ovate, becoming nearly glabrous above but remaining densely tomentose beneath, shallowly sinuate-lobed: fls. large, mostly in clusters, the calyx woolly and often spiny, the spreading, deeply lobed, purplish corolla 1 in. or more across: fr. a large berry. Afr. and S. Asia. Original habitat probably S. W. Asia.

Var. *esculentum*, Nees (*S. esculentum* and *S. ovigerum*, Dun.). COMMON EGGPLANT. GUINEA SQUASH. AUBERGINE. Figs. 1379–1381, 1383, Vol. II. Cult. for its large frs., which are usually oblong, obovoid, or egg-shaped in form, and purple, white, yellowish or striped: differs from the wild plant in having fewer spines, mostly solitary fls., and much larger and more variable frs. There are 2 well-marked subvarieties: var. *serpentinum*, Bailey. SNAKE EGGPLANT. Fr. greatly elongated and curled at the end. Var. *depressum*, Bailey. DWARF PURPLE EGGPLANT. Fig. 1382. Low and diffuse, many of the branches finally resting on the ground, usually dark-colored, nearly glabrous and always spiny: lvs. small and relatively thin, less lobed: fls. small and longer-stalked: fr. purple, pyriform. See *Eggplant*.

3629. Two solanums.—Pepino, or melon shrub, *Solanum muricatum*; and garden huckleberry, *S. nigrum* var. *guineense*, at a. (Both $\times \frac{1}{2}$)

narrowed at both ends, entire or more frequently sinuate-toothed, petioled: fls. small, white, in pedunculate lateral cymes; calyx much shorter than the corolla with small obtuse lobes; corolla about $\frac{1}{2}$ in. diam.: berry globular, black, about $\frac{1}{4}$ in. diam. A widely distributed weed in all temperate and tropical regions.—In the Dakotas, according to Hansen, the plant is often called "stubbleberry," as it volunteers freely in wheat-stubble, and the fr. is used there for pies and preserves. Hansen finds that the plants with-

AAA. Species grown wholly for ornament or curiosity.

B. Habit erect, the plant either herbaceous or woody.

C. Plant without spines, the lvs. entire or merely undulate (except sometimes in No. 13).

D. Foliage entirely glabrous.

12. *aviculare*, Forst. (*S. laciniatum*, Ait.). A leafy unarmed soft-wooded glabrous shrub 4-8 ft. high, with spreading branches, smooth or marked with raised lines

decurent from the petioles: lvs. variable in size and shape, 4-12 in. long or sometimes even longer, lanceolate or linear-lanceolate, entire or irregularly pinnatifid and the lobes linear or lanceolate and acute: fls. in cymose clusters in the axils of the upper lvs. or lateral; calyx-lobes broad and obtuse, with an abrupt point; corolla violet, $\frac{3}{4}$ -1 in. diam., the lobes short and broad: fr. a broad ovoid edible berry $\frac{3}{4}$ -1 in. long, yellowish. New Zeal.; also common in many parts of Austral., Tasmania, and in Norfolk Isl. B. M. 349.

13. *glaucum*, Dun. (*S. glaucophyllum*, Desf.). A perennial plant 6 ft. or more high, with round erect sts., suckering abundantly: lvs. 5-6 in. long, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. broad, ovate-lanceolate to oblong-lanceolate, entire, narrowed toward the base and decurrent with the petiole, acuminate at the apex, the surface glabrous and somewhat glaucous: fls. in terminal and lateral branched racemes or corymbs; corolla blue, star-shaped, about 1 in. diam., the lobes ovate: berry small, ovoid-globose, yellow. Province of Buenos Aires in Argentina, and in S. Brazil. B.M. 7945.

ceolate to oblong-lanceolate, entire, narrowed toward the base and decurrent with the petiole, acuminate at the apex, the surface glabrous and somewhat glaucous: fls. in terminal and lateral branched racemes or corymbs; corolla blue, star-shaped, about 1 in. diam., the lobes ovate: berry small, ovoid-globose, yellow. Province of Buenos Aires in Argentina, and in S. Brazil. B.M. 7945.

DD. Foliage more or less pubescent, at least on the lower surface (except in No. 14).

E. Fls. small, less than $\frac{1}{2}$ in. diam., white.

14. *Pseudo-capsicum*, Linn. JERUSALEM CHERRY. Fig. 3630. A small branching leafy shrub, reaching 3-4 ft., erect and glabrous throughout: lvs. narrowly lanceolate, oblanceolate, or oblong, entire or the margins slightly wavy, narrowed at the base to a short petiole, mostly obtuse at the apex, the surface bright green and shining, the veins prominent: fls. solitary or few in lateral clusters, small, white: fr. globose, scarlet or rarely yellow, $\frac{1}{2}$ - $\frac{3}{4}$ in. diam. Widely distributed in tropical and semi-tropical regions, naturalized in Fla. Probably a native of the Old World, perhaps Madeira. —An old-fashioned plant usually grown as small specimens in pots for its showy scarlet frs., which persist for a long time. Var. *natum*, Hort., is a dwarf compact form. Var. *Weatherillii*, Hort., Weatherill's hybrid, is a form with strongly veined undulate lvs. and pointed orange-colored frs.

15. *Hendersonii*, Hort. Very like *S. Pseudo-capsicum*, but the white fls. very numerous, and the fr. ovoid or olive-form, orange-red. A horticultural form, perhaps a hybrid. Also known as *S. hybridum Hendersonii*,

but not related to the plant known in Old-World gardens as *S. hybridum*.

16. *Capsicastrum*, Link. Fig. 3631. A small shrub resembling the last but only 1-2 ft. high: st. more or less pubescent, with stellate hairs or glabrate: lvs. simple, oval, oblong, or sometimes slightly ovate, narrowed toward the petiole, obtuse at the apex, the margins entire or slightly undulate, the upper surface green and somewhat pubescent, the lower more strongly so: fls. small, white: fr. $\frac{1}{2}$ in. diam., orange-red or scarlet. Brazil and Uruguay. F.S. 12:1242. G.W. 3:529. —Frequent greenhouse and window-plant. Var. *Mélinii*, Hort., a compact form 12-15 in. high with ovoid berries. Var. *variegatum*, Hort., has variegated lvs.

EE. Fls. usually $\frac{3}{4}$ in. or more diam., violet or rarely white in No. 22.

17. *Rantonnetii*, Carr. (incorrectly spelled *S. Rantonnei*, *Rantonni*, etc.) (*S. muticum*, N. E. Br. *S. japonicum*, Hort.). An erect bushy grayish green half-shrub, growing 3-5 ft. high, the st. marked with raised lines decurrent from the petioles: lvs. entire, lanceolate or ovate-lanceolate, narrowed to the petiole, mostly acute at the apex, glabrous or inconspicuously pubescent on the upper surface, pubescent with short hairs below: fls. 2-5, together in the axils, 1 in. or more diam.; calyx-lobes with an abrupt linear point, corolla violet with a light yellow center: the red fr. nearly or quite 1 in. diam., heart-shaped, drooping, and very ornamental. Margins of woods in Paraguay and Argentina. Cult. in warm temperate regions of Amer. and Eu. R.H. 1859, p. 135. Gt. 43:1401. —An excellent plant for blooming in the open in summer. Easily prop. by means of cuttings.

18. *crispum*, Ruiz & Pav. An unarmed shrub, or sometimes attaining the size of a small tree, with rather long green flexuous branches puberulous when young, later becoming glabrous: lvs. 3-4 in. long, entire, thin, ovate to ovate-lanceolate, subcordate at the base, acute at the apex, smooth above, the margins somewhat undulate and the nerves prominent on lower surface: corymbs many-fld., corolla pale violet, about $\frac{3}{4}$ in. broad and twice as long as the calyx, the lobes ovate or ovate-lanceolate: fr. globose, pale yellow, about the size of a pea. In Chile from the central provinces to the Island of Chiloe, also in Peru. B.M. 3795. G.C. III. 30:424.

19. *Xanti*, Gray. A low shrub or at high elevations herbaceous from a woody base, the sts. slender, 1-2 or even 3 ft. high, the younger ones angled, somewhat villous with many-celled usually gland-tipped simple hairs: lvs. membranous, ovate, ovate-oblong to oblong-lanceolate, $\frac{1}{2}$ -1 $\frac{3}{4}$ in. long, wedge-shaped, rounded or subcordate at the base, entire or lobed: fls. in umbel-like cymes, corolla $\frac{1}{2}$ -1 in. diam., rotate, angular or short-lobed, violet: fr. erect, berry-like, globose, light green or purplish in color. Throughout Calif., except in the desert region, ascending to 6,500 ft. altitude. B.M. 7821.

20. *Wallacei*, Parish. A shrubby plant often forming round masses and reaching a height of about 3 ft., the sts. densely villous with long many-celled tawny viscid hairs: lvs. rather thick, usually less densely hairy than the sts., the lower rather large, cordate, the upper ovate, rounded or subcordate at the base: fls. in rather large forked cymes, corolla 1-1 $\frac{1}{2}$ in. diam., pale violet: ripe fr. dark purple. Islands off the coast of Calif.,

3631. *Solanum Capsicastrum*. ($\times \frac{1}{2}$)

3630. *Solanum Pseudo-capsicum*. ($\times \frac{1}{2}$)

Low. Calif., and near the seacoast in Cent. Calif. The *S. Xanti* var. *Wallacei* of Gray.

21. *umbelliferum*, Esch. (*S. californicum*, Dun.). A densely villous rarely glabrate shrub: lvs. entire, usually obovate or oblong, rarely oval or ovate, $\frac{1}{2}$ -1 or 2 in. long: fls. in umbel-like terminal clusters; corolla pale violet or sometimes white, pubescent on the outer surface, $\frac{3}{4}$ in. diam., showy and fragrant: berry large, purple. Calif.—The plant offered as *S. umbellatum* is very likely this species.

CC. *Plant more or less spiny, the lvs. sinuate or lobed.*

D. *Lvs. pinnately lobed.*

E. *Species perennial.*

22. *aculeatissimum*, Jacq. (*S. ciliatum*, Lam. *S. myriacanthum*, Dun.). An undershrub 1-2 ft. high, st. branched, furnished with many long straight spines, interspersed in the younger parts with stiff bristles: lvs. solitary or geminate, broadly ovate or ovate-cordate, pinnately 5-7-lobed, 4 in. long, 3 in. wide, with rigid adpressed hairs on both surfaces, and spines on the upper surface of the principal nerves; petiole 1 in. long: cymes extra-axillary, few-fl.; calyx-lobes triangular, closely beset with spines; corolla rotate, 1 in. diam., snow-white, the lobes lanceolate: fr. globose, 1-2 in. diam., glabrous, orange or orange-yellow, flattened on the ends, corrugated. Widely distributed in tropical regions. F.S. 19:1988. F.M. 1871:521. R.B. 20, p. 249. R.H. 1888, p. 78.

EE. *Species annual.*

23. *citrullifolium*, A. Br. (*S. heterodoxum*, Brit., not Dun.). An annual plant armed with straight prickles, glandular pubescent with mostly simple hairs: lvs. 1-2-pinnatifid, the lobes obtuse and repand: infl. racemose, corolla violet, nearly $\frac{1}{2}$ in. diam., somewhat irregularly 5-cleft, the lobes ovate-acuminate,

anthers unequal, 4 of them yellow, the larger one tinged with violet: fr. inclosed in the prickly calyx. W. Texas and New Mex.

24. *sisymbriifolium*, Lam. (*S. Balbisi*, Dun.). An annual plant with many yellow- or orange-colored spines covering the st., both surfaces of the lvs., petioles, and sepals, and the upper part usually somewhat villous with gland-tipped hairs: lvs. oblong or ovate, sinuately lobed or even deeply pinnatifid and the lobes sinuate or deeply cut: infl. terminal or soon lateral, racemose, the fls. rather numerous, light blue or white and 1 in. or more diam.: fr. globose, red, 1 in. or more diam., surrounded by the at length ovate-lanceolate calyx-lobes. Trop. Amer. and naturalized in waste grounds in the Gulf states. B.M. 2828; 3954. G.C. III. 45:61.

25. *cornutum*, Lam. (*S. Fontanesianum*, Hort.). An annual herbaceous simple-stemmed spiny plant 1-4 ft. high: lvs. oval or ovate, pinnately lobed and the lobes again sometimes divided nearly to the center, the divisions oblong, acute, or rounded at the apex and tipped with an abrupt point, pubescent on both surfaces, that on the lower stellate: fls. terminal, in clusters of 3 or 4, corolla yellow, about $1\frac{1}{4}$ in. diam., villous on the outside, anthers uneven, the fifth $\frac{1}{2}$ - $\frac{3}{4}$ in. long and twice the length of the other 4, enlarged at the base and shaped somewhat like a horn, hence the name: fr. small, spiny. Mex.

DD. *Lvs. sinuately lobed.*

E. *The lvs. rusty-tomentose at least on the lower surface.*

26. *Warscewiczii*, Hort. (*S. warscewiczoides*, Hort.). Strong erect suffrutescent plant, reaching a height of about 6 ft., usually with a central st., densely rusty-tomentose and armed with many short stout hooked or straight greenish yellow spines: lvs. large, sometimes the blade a foot or more long, rather soft green and slightly pubescent at least along the veins above, grayish or rusty below and with dense stellate pubescence or tomentum, oval, somewhat cordate at the base and rather deeply lobed with unequal lobes: infl. at first terminal, later lateral in 1-sided corymbiform racemes with numerous fls.; calyx deeply lobed, the segms. oval and long-acuminate, spiny or unarmed, covered with numerous whitish hairs; corolla white, about $1\frac{1}{2}$ in. diam., the lobes lanceolate and acute: fr. pale yellow, glabrous and shining. Probably S. American. R.H. 1865, p. 430; 1896, p. 237.—A very striking plant for subtropical gardening and can easily be raised from seed in a single season; half-hardy perennial.

27. *alatum*, Seem. & Schmidt (*S. robustum*, Wendl.). Vigorous more or less spiny densely tomentose herb or subshrub, the sts. winged, 3-5 ft. high: lvs. decurrent with the spiny petiole, sometimes 1 ft. long, broadly ovate or ovate-elliptic in outline, sinuately lobed, the lobes acute, upper surface green and tomentose-velvety, woolly with more or less rusty tomentum beneath: fls. in axillary racemes, calyx unarmed, corolla about 1 in. across, white, with ovate-lanceolate acute lobes: fr. globular, small, hairy, orange-colored. Brazil. R.H. 1863, p. 250; 1896, p. 236.—Bold species, useful for subtropical gardening.

EE. *The lvs. with gray or whitish pubescence.*

F. *Fls. white.*

28. *integrifolium*, Poir. (*S. coccineum*, Hort. *S. Lobeliai*, Tenore). CHINESE SCARLET EGGPLANT. ORNAMENTAL EGGPLANT. ETHIOPIAN EGGPLANT. Fig.

3632. *Solanum integrifolium*.—A species grown for its ornamental fruit. ($\times \frac{1}{4}$)

3632. Coarse, bushy herb, 3 ft. tall, scurfy-tomentose, armed with strong hooked spines: lvs. much like those of the eggplant but the lobes sharper, spiny on the midrib and petiole: fls. small, white, in clusters of 2-6: fr. 1-2 in. across, mostly flattened on the ends but sometimes nearly globular in outline, prominently lobed, bright scarlet or yellow. Probably African.—An old-time garden plant, but little grown. Annual.

29. *marginatum*, Linn. f. A shrub 3-4 ft. high: st. terete, covered with white stellate tomentum: spines subulate, those on the upper part $\frac{3}{8}$ - $\frac{3}{4}$ in. long, on older parts 1 in. long: lvs. ovate, pinnately lobed less than half-way to the midrib or the upper ones undulately lobed, subcordate at the base, coriaceous, 3-7 in. long, 2-5 in. wide, covered with fine white stellate pubescence which in age disappears from the upper surface except near the margin, remaining silvery white beneath; spines on the principal veins often 1 in. long: cymes extra-axillary, subumbellate; pedicels covered with white stellate tomentum; calyx spiny, the lobes narrow and acute, corolla broadly campanulate, $1\frac{1}{4}$ in. diam., white with the center and midrib bluish: fr. globose, $1\frac{1}{2}$ in. diam., spiny, shining yellow and drooping. Nile Land, Abyssinia. Naturalized to a slight extent at Montecito near Santa Barbara, Calif. B.M. 1928.

FF. Fls. blue or violet.

G. Size of lvs. large, 10-15 in. long.

30. *macranthum*, Dun. (*S. maroniense*, Poit.). A shrub 6 ft. or more high, with yellowish brown straight prickles: lvs. 10-15 in. long, narrowed at the base to short winged petioles or sometimes subcordate, ovate, lanceolate or lanceolate-elliptic, sinuate-angled or lobed, pale on the lower surface with stellate pubescence, dense on the younger lvs.: fls. in simple or branched racemes 3-5 in. long and 7-12-fl.; corolla bluish violet, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. diam., the lobes acute. Brazil. B.M. 4138.

31. *macrophyllum*, Hort. An erect more or less stellate pubescent plant with curved spines: lvs. large, a foot or more long, unequal at the subcordate base, sinuate-lobed, the lobes oblong-lanceolate, acute, repand-undulate, petioles about 1 in. long, decurrent with the st.: infl. racemose; calyx-lobes with a long attenuate point; corolla large, blue, marked with yellow in the center: berry globose, yellowish, about $\frac{3}{8}$ in. diam. Mex. G. 2:283.

GG. Size of lvs. smaller, 5-7 in. long.

32. *Tóreyi*, Gray. Strong perennial herb, with close grayish stellate pubescence, prickles small and few along the st. and midribs of the lvs. or sometimes nearly wanting: lvs. 4-6 in. long, ovate with truncate or slightly cordate base, sinuately 5-7-lobed, the lobes entire or undulate, obtuse, unarmed: infl. at first terminal, cymose, 2-3-fl.; lobes of the calyx short-ovate with an acuminate point; corolla $1\frac{1}{2}$ -2 in. diam., pale blue, the lobes broadly ovate: fr. globose, smooth, 1 in. diam., pale yellow at maturity. Kans. to S. Texas. B.M. 6461.—It survives the winters at Cambridge, Mass., and spreads by running underground shoots.

33. *pyracanthum*, Jacq. An erect spiny plant with woody st. 3 ft. tall: lvs. 5-6 in. long, short-petioled, oblong, acute, deeply lobed and the lobes oblong, entire, obtuse, tomentose, spiny along the midvein: fls. numerous, in lateral racemes sometimes 6 in. long; corolla blue: fr. globose, glabrous, nearly $\frac{1}{2}$ in. diam. Probably Afr. Hort. Schoenb. 4:36. t. 470.

34. *indicum*, Linn. A much-branched prickly undershrub sometimes reaching a height of 8 ft., densely clothed when young with stellate tomentum, the prickles compressed, stout, and sometimes recurved: lvs. ovate, sinuate or lobed, 3-6 in. long and 1-4 in. broad, stellate woolly beneath and prickly along the

nerves: racemes lateral, many-fl.; fls. blue, calyx-lobes in fl. triangular, acute, very woolly, unarmed, or with slender straight spines, these becoming stronger in fr., corolla $\frac{3}{4}$ -1 in. diam., lobes broadly triangular, tomentose without, less so within: berry yellow or scarlet, glabrous, about $\frac{1}{2}$ in. diam. Very common in Trop.

3633. *Solanum Wendlandii*. (Much reduced.)

India and China, Malaya, and the Philippines. Doubtfully in the American trade.

BB. Habit of plant climbing, more or less woody, spineless (except No. 38).

C. Foliage entirely glabrous.

35. *jasminoides*, Paxt. POTATO VINE (from the fls.). Fine greenhouse twining shrub, reaching several feet in height, glabrous: lvs. rather small, the upper ones lanceolate to lance-ovate and entire, the lower ones of about 3 narrow, ovate entire lfts.: racemes short and united into a cluster 3 in. or less long and about 8-12-fl.; fls. about 1 in. across, star-shaped, white with tinge of blue; pretty. S. Amer. P.M. 8:5. B.R. 33:33. Gn. 43, p. 433; 45, p. 162; 50, p. 19; 51, p. 358; 53, p. 28.—A most useful deciduous climber for the coolhouse, and much grown. Half-hardy, and useful for the open in the S. Will grow 10-20 ft. if given a chance. Var. *grandiflorum*, Hort., has very large trusses of fls. and is a robust grower; excellent. Gng. 1:259. Var. *variegatum*, Hort., has variegated foliage.

36. *Seaforthianum*, Andr. (*S. azureum*, Hort., not Fern. *S. venustum*, Kunth). Beautiful slender unarmed herbaceous or slightly woody climber or trailer, with st. 3-4 ft. long, glabrous throughout: lvs. with 3 lfts., these $1\frac{1}{2}$ -2 in. long, or the upper ones simple, lanceolate, or ovate-lanceolate with entire or undulate margins: fls. numerous, in long drooping axillary panicles, on pedicels swollen at the apex, the corolla light purple or blue, star-shaped and usually 1 in. or less diam.: fr. ovoid or nearly globose, glabrous, scarlet. Brazil. B.M. 1982; 5823. B.R. 969. R.H. 1893, p. 177; 1897:424.—A very beautiful plant for the coolhouse. Begins to bloom when very young. Var. *album*, Hort., a variety with white fls. recently intro.

37. *Wendlandii*, Hook. f. (*S. Wendlandii magnificum*, Hort.). Fig. 3633. Tall-climbing, glabrous, with a few scattered prickles: lvs. various, sometimes 10 in. long, the uppermost simple and oblong-acuminate, the others lobed or trifoliate and with the terminal lft. much the largest, all with entire margins: fls. in large cymes, pale lilac-blue, the corolla $2\frac{1}{2}$ in. across and shallow-lobed: fr. globose. Costa Rica. B.M. 6914. G.C. III. 14:339.

G.M. 36:610. A.F. 12:1147. F.E. 8:828.—A splendid greenhouse climber, perhaps the most showy of the cult. solanums. Blooms in summer and fall. Ernest Braunton writes: "*S. Wendlandii* is a magnificent climber in this climate (Los Angeles), reaching 50 ft. or more and having umbels 12 in. across. It is perhaps the showiest vine in Calif. when in bloom. It is generally hardy here, although some winters nip and even kill the vine in the colder and lower parts of this city. Cut up an old vine, any kind of wood, stick the pieces in sand or light soil, and wait. Every cutting will grow. When in a robust condition it is a gross feeder. It should be in full sun, though it does well anywhere."

cc. Foliage usually more or less pubescent, sometimes glabrous or glabrate.

38. *Dulcamara*, Linn. BITTER-SWEET. Fig. 3634.

A more or less pubescent 3634. *Solanum Dulcamara*. ($\times \frac{1}{4}$) or sometimes glabrous shrubby climber with st. 4-6 ft. long; lvs. entire or sometimes 3-5-parted, 1-3 in. long, the entire ones cordate, ovate-cordate, or the upper ones hastate; fls. many, drooping, in paniced corymbs opposite the lvs.; corolla white or violet, $\frac{1}{2}$ in. diam., the lobes reflexed, each segm. furnished with 2 greenish spots near the base; fr. ovoid, $\frac{1}{2}$ in. diam., red or rarely yellowish green. Naturalized from Eu.—Berries poisonous.

39. *jasminifolium*, Sendt. St. round, unarmed, sparingly pubescent or glabrate; lvs. ovate to ovate-lanceolate, entire or very slightly undulate, usually subcordate at the otherwise truncate base, acute or obtuse at the apex, petiole $\frac{1}{2}$ -1 in. long, the blade 1-2 in. long; fls. several in a paniculate cluster; calyx campanulate, the lobes about equaling the tube, oblong and obtuse; corolla about $\frac{3}{4}$ in. across, deeply lobed, the lobes ovate or oval. Brazil.

40. *pénsile*, Sendt. A woody climber, more tender than *S. Wendlandii*; lvs. simple and entire, 2-4 in. long, somewhat glossy green and glabrous above, paler below, ovate or slightly cordate at the base, rarely narrowed toward the petiole; fls. in long panicles or racemes, the corolla purplish red changing to pale blue with white star-shaped center, rather deeply lobed and about 1 in. diam.; fr. globose, pale violet, about the size of a small cherry. British Guiana, the Amazon region and Surinam.

41. *Wörnsleyi*, Hort. An unarmed woody climbing plant reaching a height of about 9 ft.: lvs. soft-pubescent, oblong-lanceolate, drooping, 6-12 in. long. frs. the size of a hen's egg, clear light red in color; is a native of the highlands near Rio de Janeiro, Brazil, where it is used for the decoration of dwellings. In the unripe stage the frs. are said to be prepared and used as a vegetable. G.C. III. 27:19.

S. auriculatum, Ait., is allied to *S. verbascifolium*, and is sometimes mistaken for it. Lvs. 6-7 in. long, ovate-oblong, acuminate, entire, velvety-tomentose above with branched hairs, more densely so and paler below, axils furnished with small lvs.: corymbs subterminal, many-fld.; corolla violet, about $\frac{1}{2}$ in. across; berry globose. Afr.—*S. betaceum*, Cav., is *Cyphomandra*, for which see Vol. II.—*S. cernuum*, Velloz. Shrub or small tree, with cyphomandra-like lvs. and the young parts clothed with chaafy hairs; fls. white; fr. globose, hairy, inclosed in the calyx. S. Brazil. B.M. 7491.—*S. Commersonii*, "Violet," which attracted much attention a few years

ago, is *S. tuberosum*, being similar to, if not identical with the variety known as "Blue Giant."—*S. corymbosum*, Jacq. A fetid rather weak, unarmed, branched half-shrub; lvs. 2-5 in. long, glabrous except for the ciliate margins, ovate or lanceolate, entire or slightly lobed; fls. about $\frac{1}{2}$ in. diam. blue or violet; fr. reddish orange, $\frac{1}{4}$ - $\frac{1}{2}$ in. diam. Native of Peru.—*S. erectum* is *Cyphomandra betaceum*.—*S. Pierreanum*, Paill. & Bois, has fr. the size of a walnut and shaped like a tomato, scarlet.—*S. stoloniferum*, Schlecht. & Bouché. Tuber-bearing; lvs. with 3-4 pairs of pinnae, the interposed ones very numerous; lfts. mostly subcordate at the base and acuminate at the apex, sparingly pubescent with scattered flattened hairs on the upper surface, usually only along the veins on the lower surface, but puberulent on both surfaces; calyx glabrous, the lobes about the length of the tube; corolla white.—*S. tubingenense* and *S. Darwinianum* said to be graft hybrids of *Lycopersicon esculentum* and *S. nigrum* produced by Prof. Winkler of Tübingen. G.C. III. 50:161.—*S. verbascifolium*, Linn. Lvs. lanceolate-ovate, or ovate-oblong, entire, tomentose, without smaller lvs. in the axils; fls. rather small, white; fr. the size of a small cherry. Widely distributed in the tropics. W. F. WIGHT.

SOLDANELLA (Latin, a small coin, referring to the shape of the leaves). *Primulacæ*. Small glabrous perennial herbs with short rhizomes, hardy and useful in the border or rock-garden.

Leaves long-petioled, thick, cordate-orbicular or reniform, entire; scapes slender, solitary or few, 1-fld. or many-fld., umbellate; fls. blue, violet, or rose, rarely white, nodding, about $\frac{1}{2}$ - $\frac{3}{4}$ in. across; calyx 5-parted, segms. lanceolate, persistent; corolla hypogynous, funnellform-campanulate, 5-lobed to the middle, the lobes lacinate-lacerate; ovary superior, ovoid; caps. conic-oblong, many-seeded.—Species, 6, mountains of Eu. For account of species and cult., see Gn. 61, pp. 126, 127; for monograph, Paxt. & Knuth in *Das Pflanzenreich*, hft. 22 (IV. 237).

Soldanellas are amongst the most famous flowers of the Alps, though not the commonest. *S. alpina* ascends the mountains to the line of perpetual snow. Grant Allen, in "Flashlights on Nature," declares that the flower of soldanella actually thaws its way up through a solid block of ice. Soldanellas are cultivated in this country only in a few rock-gardens. Those who have limited resources and dwell in the region of changeable winters might attempt to grow these plants in pots under a frame in lieu of nature's winter covering. They are said to prefer a half-shady or shady position and are propagated by seed or division.

A. Fls. 2-4 on a scape; corolla split half-way to the base; filaments half as long as anthers.

B. Pedicels pubescent.

montana, Mikan. Sts. 6-14 in. high; lvs. roundish; margin slightly and remotely crenate; fls. violet. May-July. Gn. 61, p. 127. G.W. 15, p. 714.

BB. Pedicels roughish.

alpina, Linn. (*S. Clusii*, F. W. Schmidt. *S. occidentalis*, Vierh.). Fig. 3635. Sts. 3-6 in. high; lvs. roundish; base more or less kidney-shaped; margin entire or somewhat wavy; fls. violet, with darker streaks. May. B. M. 49: 2163. G.C. II. 24:457. G. 34:469. Gn. 61, p. 127. Var. *alba*, Hort., is a white-fld. form. Natural hybrids are known of which this species is one of the parents. Pyrenees, Alps, etc. Handsome species.

3635. *Soldanella alpina*. ($\times \frac{1}{2}$)

CV. *Solidago ulmifolia*, one of the common goldenrods.

AA. Fls. solitary; corolla split a third of the way to the base; filaments about as long as anthers.

B. Pedicels roughish.

pusilla, Baumg. Sts. 3-6 in. high: base of lvs. heart-shaped or kidney-shaped; margin somewhat wavy: fls. copper-colored, verging on blue, the fringes straight, not spreading. May. Gn. 61, p. 126. Var. *alba*, Hort., is a white-fl. form. G.C. III. 55:224. Gn. 78, p. 172.

BB. Pedicels pubescent.

minima, Hoppe. Sts. 3-4 in. high: lvs. roundish: fls. pale lilac, streaked purple inside; the fringes spreading at the tips. June, July. Gn. 61, p. 126. Var. *alba*, Hort., is white-fl. form. *S. Gánderi*, Huter, is a hybrid of *S. alpina* and *S. minima*.

WILHELM MILLER.

F. TRACY HUBBARD.†

SÔLEA: *Hybanthus*.

SOLENÁNTHUS (Greek, *tube* and *flower*, referring to the form of the corolla). *Boraginaceæ*. Gray-villous hirsute or rarely glabrous perennial herbs, hardy and suitable for border planting: lvs. alternate: racemes sometimes elongated and simple, sometimes short, scorpioid, densely-fl., and numerous in terminal panicles: fls. blue or rose; calyx 5-parted, segins. narrow; corolla tubular or funnelform, 5-lobed, the lobes small, obtuse; ovary 4-lobed, distinct: nutlets 4, depressed.—About 20 species, S. Eu., W. Asia, and Russia.

apenninus, Hohen. (*Cynoglossum apenninum*, Linn.). Plant hardy, 2½-3 ft. high: lvs. rather coarse, the radical ovate-oblong, those of the st. long-lanceolate: fls. blue, forget-me-not-like, in dense, axillary, paniced racemes. May, June. S. Eu.—A useful plant amongst shrubbery or in the back part of borders. Prop. by division or seed.

SOLENIÐIUM (Greek, *tube*, and *appearance*, in allusion to the shape of the fl.). *Orchidaceæ*. Epiphytic herbs with abbreviated sts. terminated by 1-2-lvd. pseudobulbs, occasionally grown in the warmhouse: lvs. rather long, thin-leathery: scape simple, axillary from below the pseudobulb: fls. in a lax raceme, medium-sized and long-pedicelled; bracts small; sepals subequal, free, spreading; petals similar to the sepals; labellum spreading at the base of the column, contracted to a long claw, dilated at the tip, undivided; column erect, broadly 2-winged, the wings spreading above into auricles and united with the membranaceous variously toothed or lobed clinandrium; pollinia 2: caps. not

known.—One species in the Colombian Andes, *S. racemodsum*, Lindl. About 6 in. high: st. shortened: lvs. rather long, ensiform, thinly coriaceous, narrowed at the base: fls. yellow, spotted with red; sepals and petals free. Nov. J.F. 4:349. Cult. like oncidium.

F. TRACY HUBBARD.

3637. *Solidago speciosa*.

SOLENOSTÈMON (Greek, *tube* and *thread*, referring to the fact that the filaments are grown together, at their base, into a tube). *Labiataæ*. Erect herbs allied to *Coleus*, probably similarly used: lvs. ovate, crenate, long-petioled: whorls of fls. laxly 6- to many-fl., arranged in long racemes or panicles: fls. small; calyx ovoid-campanulate, upper tooth ovate with decurrent edges, lateral small, lower oblong, as long as the upper; corolla-tube exserted, slender, dilated and oblique at the throat, the limb 2-lipped, upper shorter, lower long, oblong, slightly concave; stamens 4, the filaments united at their base into a tube; disk glandular: nutlets ovoid, smooth.—Eight species, W. Trop. Afr.; one also occurs in Brazil.

Godefrøyaæ, N. E. Br. (*Côleus Godefrøyaæ*, Godef.-Leb.). Herb, up to 2 ft. high, branches 4-angled: lvs. opposite, green, paler beneath, ¾-1¼ in. long, very wide-ovate or deltoid-ovate, base truncate or cuneate-truncate, slightly crenulate: racemes terminal, spike-like; fls. blue; calyx subequally 2-lipped; corolla, basal portion of tube, abruptly upcurved, upper portion abruptly deflexed, flattened-dilated, upper lip very short, crenately 4-toothed, lower lip compressed sideways. Trop. Afr. B.M. 8511. F. TRACY HUBBARD.

SOLIDAGO (according to Gray, from "*solidus* and *ago*, to make solid or draw together, in allusion to reputed vulnerary properties"). *Compositæ*. **GOLDEN-ROD**. Perennial herbs very useful for borders and for colonizing, but little known in the trade.

Erect, of various habit, with simple alternate lvs. and many small yellow (rarely whitish) heads in spikes, thyrses, compound panicles, or racemes: heads oblong or narrow-campanulate, with small mostly appressed scales, containing few florets, the disk-florets all perfect and the ray-florets in one series and pistillate: pappus of 1 or 2 rows of roughish capillary bristles.—The genus is characteristic of E. N. Amer., where about 60 species occur. There are several species on the Pacific coast, a few in Mex. and S. Amer., and 2 or 3

3636. *Solidago cæsia*.

in Eu. and N. Asia, making, altogether, perhaps 130 species. A very few of the important species may be described here; for others, the current botanical manuals should be consulted.

Amongst the glories of the American autumn are the asters and goldenrods. They complement each other. The asters run in cyanic colors, goldenrods in xanthic, —the blue and blush on the one hand and the yellow and golden on the other. Because the goldenrods are so common, they have not been appreciated for planting. They improve in the garden, however, the plants becoming larger and the bloom fuller and richer. They present few difficulties in cultivation. They may be transplanted from the wild with the greatest ease, and the stools may be lifted and divided as soon as they become root-bound and show signs of failing. Some of them become weedy if the soil is very rich. The solidagos are variable, even within the same species. Therefore it is well to mark fine individual clumps when in bloom, for removal in late autumn or early spring. The observation of a single season should result in a fine collection of individual plants. A very attractive grouping of asters and goldenrods can be made entirely of native species:

3638. *Solidago canadensis*.3639. *Solidago nemoralis*.3640. *Solidago rugosa*.

with a background of sumac, the autumnal colors of which are beautifully harmonized by the blues and purples of the asters and the yellows and cream-yellows of the goldenrods.

A. Heads in small axillary clusters, not usually in large terminal infl.

cæsia, Linn. WREATH GOLDENROD. Fig. 3636. A smooth slender perennial, often glaucous, simple or sometimes branched: lvs. stalkless, acuminate, the base narrowed, sharply toothed, $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long: fls. in axillary racemes or head-like clusters, yellow or sometimes whitish: involucre bracts obtuse. E. N. Amer. Aug.–Oct.—Useful as a partial shade plant or in the open border.

AA. Heads in a large terminal infl. which is not composed of 1-sided clusters of fls. (secund).

B. Lvs. serrate.

speciosa, Nutt. Fig. 3637. Stout, smooth, usually simple-stemmed perennial, smooth below, often rough above: lvs. glabrous, firm, the basal 3–6 in. long and $\frac{3}{4}$ – $1\frac{1}{2}$ in. wide, diminishing in size above, crenate, pinnately veined: heads in a large showy terminal

thyrsus, the branches of which are ascending and often leafy: bracts of the involucre oblong, very blunt. Rich soil, E. N. Amer. A.G. 13:583. G.F. 3:561 (adapted in Fig. 3637).—Excellent for half-shady border.

BB. Lvs. entire or essentially so.

Virgaurea, Linn. EUROPEAN GOLDENROD. A rough simple-stemmed but stout perennial 1–3 ft. high: basal lvs. 4–7 in. long, 2 – $2\frac{1}{2}$ in. wide, obtuse or acute; upper lvs. sessile or narrowed into margined petioles: fls. in a dense terminal, rather narrow and often interrupted thyrsus which is often 8–10 in. long: bracts of the involucre acute or acutish. Eu. G. 27:7.—One of the best garden plants of the group. A prostrate form is offered. *S. cæmbrica*, Huds., is a compact and dwarf form, 6 in. or less high, with larger heads. *S. Virgaurea* is represented in the U. S. by *S. Cùleri*, Fern. (*S. Virgaurea* var. *alpina*, Bigel.), in the highest alpine districts of N. New England and N. Y.; this American species appears not to be in the trade.

AAA. Heads in a terminal infl., usually a panicle, which is composed of 1-sided branches or clusters (secund).

B. Foliage fragrant; lvs. pinnately veined.

odora, Ait. SWEET GOLDENROD. A slender, simple-stemmed, anise-scented perennial about 18–24 in. high: lvs. dotted, quite entire, acute or acuminate, $2\frac{1}{2}$ –4 in. long, lanceolate: fls. in a small, not very showy cluster, but persisting many weeks; tips of the involucre bracts acute. E. U. S.—Good for dry sandy open places. July–Sept.

BB. Foliage not fragrant; lvs. triple-nerved, with a pair of lateral veins beside the midrib.

C. Lower lvs. lanceolate, sharply serrate.

canadensis, Linn. Fig. 3638. St. 3–5 ft., stout, hairy and usually much branched: lvs. acute at each end, the lower sharply serrate, lanceolate, 3–7 in. long, $\frac{3}{4}$ – $1\frac{1}{2}$ in. wide, the upper smaller and often entire: fls. in a very large terminal secund panicle, involucre bracts linear, obtuse or acutish. In dry soil, E. N. Amer.—There are many wild forms but none seems to be in the trade. Aug.–Nov. This is a coarse and somewhat weedy species; very common.

cc. *Lower lvs. oblanceolate, merely crenate or entire.*

memoralis, Ait. Fig. 3639. St. slender, hairy, 18–24 in. tall: lvs. thick, roughish, the lower petioled, oblanceolate, crenate; upper lvs. becoming smaller, linear-oblong, acutish and entire: fls. in a 1-sided panicle, not very large or showy; bracts of the involucre linear-oblong, obtuse. In dry open places, E. N. Amer.—Aug.–Oct. Good for the sunny border and the fls. usually very persistent.

BBB. *Foliage not fragrant; lvs. pinnate-veined, rough.*

rugosa, Mill. Fig. 3640. Stout erect mostly stiff plant, to 7 ft., hairy: lvs. crowded above, lanceolate to ovate-lanceolate, sharply serrate, more or less rugose: heads in a broad pyramidal panicle, closely arranged on one side of the curving branches. Canada and U. S.

Any number of *Solidagos* may be offered in lists, but they are scarcely trade commodities. *S. Buckleyi*, Torr. & Gray, N. C. to Ala., is a plant described as 2 or 3 ft. high, with ovate-oblong to oblong-lanceolate lvs., and heads in a loose and elongated thyrs; the name is listed abroad, the plant said to be "suitable for rock-garden, later summer-flowering, yellow, 1 ft."—*S. flexuosa*, *S. gigantea*, *S. laevigata*, are also listed, but the writers do not know what plants pass under these names in cult.—*S. sempervirens*, Linn. A maritime fleshy-lyd. smooth plant, tall and stout, 2–4 ft. and more: lvs. entire, lanceolate to lance-oblong; heads in short racemes which are disposed in a panicle. Atlantic seaboard of the U. S.—*S. speciosa*, Gray. Plant 1–2½ ft. tall: lvs. lanceolate to linear, the lower oblong or more or less spatulate and sparingly serrate: heads golden yellow, numerous and crowded in a thyrs. Nev. to Calif.

L. H. B.

N. TAYLOR.

SÓLLYA (in honor of Richard Horsman Solly, 1778–1858, an English botanist). *Pittosporaceae*. Evergreen climbing subshrubs, ornamental greenhouse plants and hardy outdoors in the South.

Leaves narrow, entire or rarely sinuate: fls. nodding, at the ends of the branches, in lax, few-fld. cymes or rarely 1-fld., blue; sepals small, distinct, petals obovate, spreading from the base; anthers connivent in a cone around the ovary; ovary subsessile, perfectly 2-celled: berry oblong, indehiscent.—About 3 species, Austral. Prop. by cuttings in sand under glass, or by seeds, which germinate readily.

heterophylla, Lindl. AUSTRALIAN BLUEBELL CREEPER. Fig. 3641. Small shrub, 2–6 ft. high, with slender, twining sts.: lvs. variable, from lanceolate or oblong-linear to ovate-lanceolate, or ovate-oblong, obtuse or slightly acuminate, entire, 1–2 in. long, usually narrowed into short petioles: cymes 4–8–12-fld., terminal or lf.-opposed: fls. bright blue, ½–¾ in. long. July. B.M. 3523. R.B. 21:253. B.R. 1466.—Hardy and much cult. in Cent. Calif. and a great favorite on account of the brilliant blue of its fls. Especially valuable for covering banks, rockwork, and low fences, preferring to scramble over other plants. Also grown as an herbaceous border plant, being kept within bounds by the shears. The roots are very attractive to the California pocket-gopher, who plays sad havoc with it if not watched. Sometimes seen in greenhouses.

parviflora, Turcz. Much more slender and twining than *S. heterophylla*, usually loosely soft-hairy: lvs. lanceolate or oblong-linear, the larger about 1 in. long, very short-petioled and thinner than the preceding: fls. small, solitary, or 2–3 in a cyme; pedicels filiform; berry ½–¾ in. long, tapering at both ends. W. Austral.

Drummondii, Morr. St. weak, flexuous-twining to the left, prostrate, pubescent: lvs. alternate, linear-lanceolate, both ends acute, scarcely petioled, nerves pilose: cymes 2-fld. or the fls. solitary, terminal; peduncles rather glabrous: fl. nodding; sepals linear, villous. Austral. B.H. 4:33. F. TRACY HUBBARD.†

SOLOMON'S SEAL: *Polygonatum*. False S. S.: *Smilacina*.

SÓNCHUS (the Greek name). *Compositae*. Mostly weedy plants, but some of the Canary Island species are good foliage subjects.

Annual or perennial, usually more or less succulent, sometimes frutescent, leafy-stemmed, mostly smooth and glaucous, summer-flowering: lvs. usually clasping entire, toothed or runcinate-lobed or even pinnatifid and lacinate, more or less prickly-margined: heads homogamous and ligulate, yellow-fld., with more or less imbricated involucre bracts, becoming thickened or tumid at base, corymbose or paniculate: achenes ribbed or costate, not beaked, with fine white pappus.—Species 40 or more, in the Old World, some of them intro. in N. Amer. as weeds.

Certain bold foliage plants of this genus are more or less listed and mentioned abroad, the botanical identity of which is to be determined. *S. arboreus laciniatus* described as a "magnificent foliage plant with lacinated lvs.," is probably a form of *S. pinnatus*, Ait., which grows 3 ft. or so high, bearing glabrous pinnately parted lvs. with narrow entire or toothed lobes, native of Madeira. What is mentioned abroad and also in S. Calif. as *S. Jacquini*, is probably *S. congestus*, Willd., described as a beautiful foliage plant with long and broad crowded recurved oblanceolate more or less pinnatifid lvs. (1 ft. or less long and 2–3 in. broad) and

showy panicles of yellow heads 2–3 in. across; Canary Isls., where it is known as pastor's lettuce (*lachuza de pastor*), perhaps in allusion to availability of the lvs. for salad. The lvs. of other species of *Sonchus* are said sometimes to be similarly used. The names *S. elegantissimus* and *S. laciniatus* sometimes appear in horticultural literature, representing ornamental plants with much-divided lvs., the segms., very narrow; they are probably forms of Canary or Madeira species. L. H. B.

3641. *Sollya heterophylla*. (× ½)

with ornamental foliage, suitable for the greenhouse.

Leaves similar or dimorphous, often membranaceous, entire or serrulate, 3–5-nerved: fls. in scorpioid racemes or spikes, frequently rose, rather large or some small; calyx glabrous or setose, tube turbinate, oblong or campanulate, 3-lobed, the lobes short; petals 3, ovate, obovate, or oblong; stamens 3 (rarely 6, the alternate ones smaller); ovary adherent or almost so to the tube of the calyx, 3-celled: caps. included in the turbinate, cylindrical, ribbed or 3-angled tube of the calyx, 3-valved.—About 75 species, India and the Malay Archipelago. This includes a number of dwarf tender foliage plants which must be grown in the greenhouse all the year round. The plants belong to the same cultural group with *Bertolonia*, *Gravesia*, and *Monolena*, and are distinguished by having their floral parts in 3's. The fls. are usually rose-colored, ½ in. across or less, and generally disposed in scorpioid racemes or spikes. The species described here are all caulescent plants with lvs. distinctly petioled, those of each pair being of equal size (except in *S. maculata*): fls. 3-merous; stamens 3, long-acuminate.

It was long thought impossible to grow *sonerila* and its allies outside of a bell-jar or Wardian case. Gardeners now dispense with the "double glass" and

grow these plants in tropical or even temperate green-houses. For potting material they use a compost of fibrous peat and chopped sphagnum, sprinkled with sand and interspersed with bits of charcoal. The plants should have a partially shaded position, and should never be syringed. Never allow water to remain on the leaves. The species seed freely. The varieties are propagated by division.

Sonerilas thrive best in a close and moisture-laden atmosphere with just enough ventilation to keep them from melting or decaying. A temperature of not less than 75° suits them best. Cuttings of well-ripened growth are placed under a glass case or bell-glass in a bottom heat of 70° to 80°. Care must be taken every morning to allow the drops of condensation which gather on the glass to dissipate. For potting material use fine-screened leaf-mold, with plenty of silver sand intermixed and a little finely chopped fresh sphagnum on the top of the pots or pans. These plants have shallow roots, and require plenty of drainage, consisting of fine broken potsherds mixed with either charcoal or finely ground soft-coal clinkers. When the plants have made their full growth (which they do if started at the proper time in early spring) they start into flower. At this time the plants should be hardened off by gradually withholding water, and they should also be kept a little cooler. When fully ripened they may be cut back in order to furnish material for cuttings. Keep the old stools a little warmer and they will gradually start into new growth again. These plants make choice decorative plants in pans or even in wire baskets and can be used for choice table or mantel decorations. (H. A. Siebrecht.)

KEY TO THE SPECIES.

- A. Foliage not variegated..... 1. *speciosa*
- AA. Foliage variegated.
 - B. Calyx with rather long and sparse glandular hairs.
 - c. Margins of lvs. ciliate..... 2. *maculata*
 - cc. Margins of lvs. not ciliate..... 3. *læta*
 - BB. Calyx glabrous or rarely dotted-scurfy.
 - c. Number of nerves 7: margin of lvs. minutely serrate..... 4. *picta*
 - cc. Number of nerves 9 or 7: margin of lvs. sharply and prominently serrate.
 - D. Color of nerves dark purple: lvs. covered with short, dark purple hairs..... 5. *orientalis*
 - DD. Color of nerves green: lvs. glandular-pubescent, the pubescence not purplish.
 - E. Lvs. with a dark green ground, and pearl-like spots of regular size and arrangement... 6. *margaritacea*
 - EE. Lvs. with a dark green ground, and irregular light-colored blotches between the veins..... 7. *Hendersonii*
 - EEE. Lvs. silvery, only the nerves dark green..... 8. *argentea*

1. *speciosa*, Zenker. This is practically the only species cult. for its fls.: height 1 ft.: lvs. opposite, cordate-ovate, green above, sometimes crimson beneath, mostly 7-9-nerved: fls. purple or rose, 4-14 in a cluster, 1 in. across. India. B.M. 4978 (as *S. elegans*); 5026. F.S. 23:2442.

2. *maculata*, Roxbg. This differs from the other species here described in having lvs. of unequal sizes. The larger one of each pair may be 3-5 in. long; the smaller a half or third as long; lvs. ovate or oblong, unequal at the base, minutely denticulate, 9-11-nerved: fls. violet.

India. R.H. 1865, p. 91, is too poor to determine.—Probably not in cult.

3. *læta*, Stapf. Erect herb, 6 in. high: st. terete, glandular-puberulent: lvs. petioled, ovate or elliptic-ovate, symmetrical or a little asymmetrical, not ciliate-margined, the larger lvs. up to 4 x 2 in., green but white-spotted above, purple and green-spotted beneath: cyme terminal, contracted, 7-flid.; calyx oblong-cylindrical, purple; petals oblong, subacuminate. China.—Closely related to *S. maculata*.

4. *picta*, Korth. Erect or ascending, with scurfy or puberulous branches: lvs. short-petioled, broadly lanceolate, wedge-shaped at the base, minutely serrate, 7-nerved, lined with white along the primary nerves: fls. rosy. Sumatra.—*S. picta* of the trade is probably *S. orientalis* var. *picta*.

5. *orientalis*, Lind. The botanical status of this name is doubtful. In horticulture it applies to a group of varieties sent out by Wm. Bull in 1891, and remarkable for two novel features: some of the varieties have dark purple or bronzy colors; others are peppered all over with an infinite number of small, light-colored dots. All have dark purple nerves. G.W. 6, p. 327. In I.H. 37:113 the lvs. are shown as ovate, acuminate, more or less cordate and unequal at the base, with 9 or 10 nerves, entire: color of fls. not recorded. Habitat not stated. The typical form is said to have bronzy lvs. with an amaranth reverse. Var. *guttulata*, Hort., has green lvs. peppered with small white dots and is pale green below. Var. *punctata*, Hort., is much like the preceding variety but has paler lvs. Var. *picta*, Hort., has purplish lvs. of the type, with an irregular lanceolate strip of silvery gray down the middle. Var. Robert Sallier, R.B. 20:61, has dark green lvs. peppered white and with a lanceolate figure of silver down the middle. Said to be a hybrid of vars. *picta* and *punctata*. It has the stripe of one and the dots of the other.

6. *margaritacea*, Lindl. This is the most important species. The name "*margaritacea*" means "pearly," referring to the regular rows of pearly spots between the nerves and parallel with them, which are characteristic of the typical form. Lvs. ovate-lanceolate, acutely serrate, 7-9-nerved, glabrous, purplish below, acute at the base: fls. rosy. B.M. 5104. F.S. 11:1126 (nerves too parallel). I.H. 2:40. G.W. 6, p. 326. H.F. II. 4:72. Lowe 16.—Supposed to be native of Java. In Vol. II, edition 1, page 684, *Gravasia guttata* var. *margaritacea* is erroneously referred to *Sonerila* instead of *Salpinga*. *Salpinga margaritacea* is readily told from *Sonerila margaritacea* by its 5-nerved lvs. and floral parts in 5's.

7. *Hendersonii*, Hort. (*S. margaritacea* var. *Hendersonii*, Hort.). This is referred by Cogniaux to *S. margaritacea*, of which it is perhaps merely a horticultural variety. For trade purposes it is convenient to treat it like a distinct species. It seems to be the chief parent in the development of the numerous hybrids with blotched foliage. It differs from the type in having a broader lf. with a shorter acumen and rounded base, and especially in being covered with irregular blotches, which, however, do not cross the nerves. F.M. 1875:159. I.H. 23:230. G.W. 2, p. 285. G.Z. 19:161.—The blotches are all about the same size. *S. Mamei*, Lind., has more regular and roundish blotches, which are nearer white and on a darker ground, the under side netted with rosy purple. I.H. 23:254.

8. *argentea*, Hort. (*S. Hendersonii* var. *argentea*, Fournier). For horticultural purposes this may be treated as a distinct species, characterized by its silvery foliage, resembling that of certain begonias, with no dark green except on the nerves. This is the parent of most of the forms that have a silvery cast of foliage, just as *S. Hendersonii* is responsible for the irregular blotches. G.W. 6, p. 325.

A very handsome hybrid between the *orientalis* and *margaritacea* groups is called Mme. Paul du Toit. It has the serrate lfs. and some of the silveriness of *S. argentea*, with the numberless minute dots of the *S. orientalis* group. It is much like Robert Salier, but the central coloring is bronzy as well as silvery and more broken up by the green.

S. marmorata and *S. picturata* of the trade are not accounted for botanically.

WILHELM MILLER.

F. TRACY HUBBARD.†

SÓPHORA (*Sophora*, Arabian name of a tree with pea-shaped flowers). Including *Styphnolobium* and *Edwardsia*. *Leguminosæ*. Ornamental woody or rarely herbaceous plants grown chiefly for their attractive flowers and handsome foliage.

Deciduous or evergreen useful ornamental plants: lvs. alternate, odd-pinnate with opposite usually small entire lfts.: fls. pea-like, in racemes or terminal leafy panicles; calyx with 5 short teeth; standard orbicular or broadly obovate; stamens 10, free or connate only at the base; pod stalked, almost terete or 4-winged, rarely compressed, few- to many-seeded, moniliform, indehiscent or tardily dehiscent.—About 25 species in the temperate and subtropical regions of both hemispheres. The fls. and frs. of *S. japonica* yield a yellow dye, *S. tomentosa* has medicinal properties, and the seeds of *S. secundiflora* contain sophorine, a poisonous alkaloid. *S. tetraptera* is a valuable timber tree in its native country.

The sophoras are handsome trees, rarely shrubs or herbs with graceful foliage, evergreen in some species, and with papilionaceous whitish, violet or pink, or yellow flowers in terminal panicles or in racemes, followed by long and narrow moniliform pods. *Sophora japonica* and the shrubby *S. viciifolia* are hardy as far north as Massachusetts, while *S. affinis* is less hardy. The evergreen species are tender and can be grown only in the southern states and California; they are very showy in spring when they are in bloom; in England they are often planted against a wall, where they can be easily protected against light frost. *S. japonica* is especially valuable for its late-appearing flowers, which are white and disposed in ample panicles; the foliage is dark green and graceful and the tree is conspicuous in winter on account of its dark green branches. It is sometimes planted as a street tree, as it stands heat and drought well. The sophoras thrive best in well-drained sandy loam but grow fairly well in rather dry soil. Propagation is by seeds and the varieties by grafting on the typical form; some species are also increased by greenwood cuttings and by layers.

B. Lfts. $\frac{1}{2}$ in. long, or less: spinescent shrub.

1. *viciifolia*, Hance (*S. Davidii*, Komarov. *S. Moorcroftiana* var. *Davidii*, Franch.). Fig. 3642. Spi-

nescent shrub, to 6 ft., with slender spreading pubescent branchlets: lvs. 1–1½ in. long, short-petioled; lfts. 11–15, sessile, elliptic, obtuse, and mucronulate, pubescent beneath, $\frac{1}{4}$ – $\frac{1}{2}$ in. long: fls. bluish violet or nearly white, about $\frac{1}{2}$ in. long, in short, 6–12-fl. racemes terminal on short branchlets; calyx shortly 5-toothed,

3643. *Sophora japonica*. ($\times \frac{1}{4}$)

violet; petals of nearly equal length; standard spatulate-obovate, reflexed; pod about 2 in. long, slender, long-beaked, glabrous. June, July. Cent. and W. China. B.M. 7883. A.F. 29:155. G.C. III. 36:3. Gn. 68, p. 87; 78, p. 469. Gng. 16:3. G.W. 11, p. 139.—Graceful shrub; has proved quite hardy at the Arnold Arboretum.

BB. Lfts. larger: unarmed trees.

c. Fls. in large terminal panicles.

2. *japonica*, Linn. (*Styphnolobium japonicum*, Schott). JAPAN PAGODA TREE. Figs. 3643, 3644. Tree, attaining 60 ft., with spreading branches, forming a dense round head: lvs. 7–9 in. long; lfts. 7–17, distinctly stalked, ovate to ovate-lanceolate, acute, rounded at base, dark green and glossy above, more or less pubescent beneath, 1–2 in. long: fls. yellowish white, $\frac{1}{2}$ in. long, in loose panicles 15 in. long: pod distinctly stalked, glabrous, terete, 2–3 in. long, $\frac{1}{3}$ in. broad. July–Sept. China; cult. in Japan. Gn. 24, pp. 210, 211, 214; 29, p. 222; 73, p. 43. G.M. 38:665. Gng. 6, p. 247. M.D.G. 1898:183. F.E. 12:1174. G.W. 8, p. 615; 12, p. 200; 13, p. 243. Var. *pendula*, Loud. Figs. 3645, 3646. With long and slender pendulous branches. R.H. 1876:194, 195 (adapted in Figs. 3645, 3646). Gn. 9, pp. 600, 601; 24, pp. 202, 203, 211; 28, p. 27. M.D.G. 1898:182 G. 6:257. Gn.M. 2:106. G.C. III. 28:479. F.E. 14:1430, pl. 43. Var. *columnaris*, Schwerin. Of narrow pyramidal habit. Var. *violacea*, Carr. (*S. violacea*, Dipp., not Thwaites). Lfts. 15–17, sparingly pubescent above, densely so beneath, acute: fls. with pinkish lilac wings and keel, standard white.—The plants cult. as *S. tomentosa*, *S. sinensis*, and *S. Korolkowii* also belong to this species. The first, which is not to be confused with *S. tomentosa*, Linn. (see suppl. list), has 15–19, smaller and broader, elliptic lfts. densely pubescent beneath, less so above; the second has pale pink fls. and 11–17

3642. *Sophora viciifolia*. ($\times \frac{3}{8}$)

ovate to ovate-oblong lfts. soft-pubescent beneath; the third has larger oblong-lanceolate lfts. broadly cuneate at the base and slightly pubescent beneath. There is also a form with variegated lvs.

cc. Fls. in racemes.

d. Foliage deciduous: racemes axillary.

3. *affinis*, Torr. & Gray. Small round-headed tree, with slender branches, to 20 ft.: lfts. 13-19, elliptic,

3644. Pod of *Sophora japonica*. (×1)

obtusish or emarginate, broadly cuneate at the base, glabrous or with scattered hairs below, conspicuously veined, 1-1½ in. long: fls. ½ in. long, white tinged with rose, with the lvs. in axillary nodding racemes 3-5 in. long: pod terete, moniliform, more or less pubescent, ½-3 in. long, black. Spring. Ark., Texas. S.S. 3:122.

dd. Foliage evergreen: racemes terminal.

4. *secundiflora*, Lag. Small tree, 35 ft. high, with short, slender trunk and upright branches forming a narrow head or shrubby: lvs. 4-6 in. long; lfts. 7-9, elliptic or ovate-oblong to oblong, rounded or emarginate at the apex, cuneate at the base, silky-pubescent while young, dark yellowish green above, 1-2½ in. long: fls. violet-blue, the standard marked near the base with a few dark spots, very fragrant, about 1 in. long, in 1-sided racemes 2-3 in. long: pod white-tomentose, terete, 1-7 in. long, ½-¾ in. thick; seed bright scarlet. Spring. Texas to New Mex. S.S. 3:121. R.H. 1854:201.—On account of its handsome fragrant fls., to be recommended for planting South.

AA. Fls. yellow, in axillary racemes: lvs. evergreen. (*Edwardsia*.)

B. Pod 4-winged: fls. about 1½ in. long.

5. *tetraptera*, Ait. (*Edwardsia tetraptera*, Poir.). Shrub or small tree, 30, rarely 40 ft. high, with slender spreading branches: lfts. very numerous, almost sessile,

3645. *Sophora japonica* var. *pendula*, in winter.

obovate to linear-oblong, silky-pubescent: fls. in 2-8-fld. racemes, pendulous, about 1½ in. long: pod 4-winged, 7 in. long. Spring. New Zeal., Lord Howe Isl., Juan Fernandez, Chile. G. 29:185.—The following varieties are in cult.: Var. *grandiflora*, Hook. f. (*Edwardsia grandiflora*, Salisb.). Lfts. linear-oblong, obtuse,

appressed silky-pubescent on both sides, about 1 in. long, in 10-25 pairs: fls. 1½ in. long; standard shorter than wings. B.M. 167. G.C. II. 9:729. Gn. 24, p. 211; 76, p. 292. L.B.C. 12:1162. G. 5:593; 10:445. Var. *microphylla*, Hook. f. (*S. microphylla*, Ait. *Edwardsia Macnabiana*, Curt.). Lfts. orbicular-obovate to broadly oblong, usually emarginate, glabrous or nearly so above, sparingly pubescent beneath, sometimes only on the midrib, ¼-½ in. long: fls. about 1½ in. long; standard about as long as wings. B.M. 1442; 3735. G. 34:503, 505. Gn. 24, p. 211. Gn. 12:87 also seems to belong here.

6. *chrysophylla*, Seem. (*Edwardsia chrysophylla*, Salisb.). Tree, to 30 ft.: lfts. 13-21, obovate-oblong or oblong, obtuse, tawny or grayish pubescent beneath, less so above, rarely glabrescent, ½-1 in. long: fls. pale yellow, about 1 in. long; standard slightly shorter than wings: pod 4-winged, 4-6 in. long. Hawaiian Isls. B.R. 738.

3646. *Sophora japonica* var. *pendula*, in summer.

BB. Pod not winged: fls. ¾-1 in. long.

7. *macrocarpa*, Smith (*Edwardsia chilensis*, Miers). Shrub or small tree, with the young branchlets densely tomentose: lfts. in 10-20 pairs, elliptic or obovate obtuse, silky-pubescent beneath, ¾-1 in. long: fls. ¾-1 in. long, in short racemes; standard as long as wings: pod terete, not winged, 1-4-seeded. Chile. L.B.C. 12:1125. B.R. 2798.

S. alopecuroides, Linn. Grayish-pubescent undershrub, with upright, virgate branches: lvs. 6 in. long, with 15-25 oblong lfts.: fls. yellow: racemes dense, terminal, about 6 in. long: pod terete, 6-12-seeded. W. Asia to Himalayas. Half-hardy.—*S. australis*, Linn.—*Baptisia australis*.—*S. platycarpa*, Maxim.—*Cladrastis platycarpa*.—*S. tomentosa*, Linn. Pubescent shrub: lvs. 6-10 in. long; lfts. 15-19, oval to oblong, obtuse, 1-1¼ in. long: fls. yellow, in terminal 6-12-in. long racemes: pod 4-6 in. long. Southern states, W. India. B.M. 3390. Not hardy North.

GEORGE V. NASH.

SOPHRONITIS (Greek, *modest*). *Orchidaceæ*. Dwarf epiphytic orchids, cultivated on account of their neat habit and brilliantly colored flowers.

Pseudobulbs small, with 1 or rarely 2 small flat lvs.: fls. from the top of the pseudobulbs, brightly colored; sepals and petals nearly equal, spreading; labellum with a broad middle lobe and small erect side lobes, the base leading into a cavity in the wall of the ovary; column short, the stigmatic surface covering 2 wing-like projections at its summit; pollinia 8.—About 6 species, closely related to *Lælia*, *Cattleya*, and the like; Brazil.

These plants, and also *soprocattleyas* and *sophrœlias*, thrive in the temperature of the cattleya house. In growing season, give a moderate supply of water and plenty of fresh air. Rest them at 50° to 55°, and water sufficiently to keep them from shriveling. Grow them in shallow pots with plenty of drainage, and a thin layer of fine turfy fern-root, using no sphagnum. (Wm. Mathews.)

grandiflora, Lindl. (*S. coccinea*, Reichb. f.). Pseudobulbs clustered: lvs. about 2 in. long, elliptic: fls. solitary, on short peduncles, 1½–4 in. across, brilliant scarlet, often with a shade of orange, with an orange labellum; sepals oblong-lanceolate; petals broadly elliptic; labellum narrow, with folded sides. Flowers during the whole winter. Organ Mts. B.M. 3709. F.S. 1:22; 17:1716. P.M. 9:193. Gn. 25:474 (var. *rosea*); 31, p. 358; 43:82. I.H. 34:32. J.H. III. 34:319; 62:13. G.C. II. 22:561; III. 9:669; 17:492; 21:266; 43:281. G.M. 56:99. R.H. 1886:492 (var. *aurantiaca*). A.F. 6:609.

cernua, Lindl. Very small plants with a creeping rhizome bearing 1-lvd. pseudobulbs: lvs. ovate, thick and leathery, a little over an inch long; fls. 4–8, on a st. from the axils of the lvs., bright scarlet or reddish orange, with an orange lip; sepals and petals ovate; labellum ovate-acuminate, shorter, concave. Winter. Rio Janeiro. B.M. 3677. B.R. 1129.

violæcea, Lindl. One of the smallest of cult. orchids: pseudobulbs ovoid, 1 in. long: lvs. linear, 2–3 in. long: fls. bright rose, about 1 in. diam.; sepals and petals oblong-lanceolate, acute; labellum rhombic-obovate, flat. Winter. Organ Mts., Brazil. B.M. 6880.

HEINRICH HASSELBRING.

SORBARIA (derived from *Sorbus*: the leaves resemble those of the mountain-ash). Syn., *Basilima*. *Rosaceæ*. Ornamental woody plants chiefly grown for their large panicles of white flowers and the handsome pinnate foliage.

Deciduous shrubs: lvs. alternate, odd-pinnate, with serrate lfts., stipulate: fls. in terminal panicles; sepals and petals 5; stamens 20–50: carpels 5, opposite to the calyx-lobes, partly connate, dehiscent at the ventral suture, with several seeds.—Eight species in E.

Asia. Formerly usually united with *Spiræa* but easily distinguished by the stipulate, pinnate lvs. and the 5 carpels being opposite to the sepals.

The sorbarias are very handsome upright shrubs with rather large bright green pinnate leaves and small white flowers in large and showy panicles appearing in summer and followed by small capsular fruits; the panicles, however, after the flowers have faded and dried up, become rather unsightly and should be removed. *S. sorbifolia* is hardy North and *S. stellipila*, *S. assurgens*, and *S. arborea* have proved hardy at least as far north as Massachusetts, while *S. Aitchisonii* is somewhat tenderer and *S. Lindleyana* still more so. They are well adapted for borders of shrubberies and woods or for planting on banks of brooks or rivers, but should not be brought together with slow-growing and delicate shrubs, as they spread in suitable soil rather rapidly by means of suckers and are likely to overcrowd other plants. The handsome bright green foliage appears

very early in spring. They are all much alike in habit, but flower at different times from June to September, beginning with *S. sorbifolia*, followed in order by *S. stellipila*, *S. assurgens*, *S. arborea*, and *S. Aitchisonii* which usually continues flowering until September. They grow best in a somewhat moist and rich soil and thrive also in partly shaded situations. Propagation is by hardwood cuttings; also by root-cuttings, suckers, and seeds, like *spirea*.

A. Lfts. doubly and sharply serrate, ½ in. or more wide.

B. Panicles with upright ramifications, dense.

C. Stamens 40–50: lfts. usually 20 pairs of veins.

sorbifolia, A. Braun (*Spiræa sorbifolia*, Linn. *Basilima sorbifolia*, Raf.). Fig. 3647. Upright shrub, 3–5 ft. high, much spreading by suckers: lfts. 13–23, lanceolate or ovate-lanceolate, long-acuminate,

3647. *Sorbaria sorbifolia*.—Often known as *Spiræa sorbifolia*. (× ½)

nate, doubly serrate, stellate-pubescent beneath when young or glabrous, 3–4 in. long; panicles 5–10 in. long; fls. ½ in. across: carpels and frs. glabrous. June, July. N. Asia, from Ural to Japan. A.G. 11:125. Gn. 16, p. 217. F.E. 30:777.—Sometimes escaped from cult.

stellipila, Schneid. (*S. sorbifolia* var. *stellipila*, Maxim.) Shrub, to 5 ft.: branchlets pubescent: lfts. 11–19, oblong-lanceolate to lanceolate, long-acuminate, stellate-pubescent beneath, 2–3½ in. long; infl. puberulous, 8–10 in. long; calyx pubescent: carpels and frs. pubescent. July. N. E. Asia, Japan. G.W. 15, p. 651.

cc. Stamens about 20: lfts. with 25 or more pairs of veins.

assurgens, Rehd. Shrub, to 8 ft., with upright or ascending sts.: lfts. 13–17, oblong-lanceolate to narrow-lanceolate, long-acuminate, cuneate at the base, often falcate, pubescent on the veins beneath, 2–3½ in. long; panicle 6–12 in. long, puberulous; stamens longer than petals: carpels and frs. glabrous. July. China. V.F. 75.

BB. Panicles with spreading ramifications, open.

Lindleyana, Maxim. (*Spiræa Lindleyana*, Wall. *Basilima Lindleyana*, Kuntze). Four to 8 ft. high: lfts.

15-21, lanceolate, long-acuminate, rounded or nearly so at the base, doubly serrate, with simple hairs beneath when young, 3-4 in. long; panicles 8-12 in. long and about 8 in. broad; fls. $\frac{1}{4}$ in. across; stamens as long as petals or shorter. July, Aug. Himalayas, China. F.S. 2:108. B.R. 31:33. Gn. 47, p. 222; 49, p. 229; 55, p. 116; 77, p. 487; 78, p. 126. G.C. III. 43:415. G. 33:507.

arborea, Schneid. (*Spiræa arborea*, Bean). Shrub, to 20 ft.: lfts. 13-15, ovate-oblong to lanceolate, long-acuminate, usually broadly cuneate at the base, stellate-pubescent or nearly glabrous beneath, $1\frac{1}{2}$ - $3\frac{1}{2}$ in. long; panicles 8-12 in. long, 6-8 in. wide; fls. $\frac{1}{4}$ - $\frac{1}{2}$ in. across; stamens much longer than petals. July, Aug. Cent. China. Gn. 77, p. 424. G.M. 61:603. G. 35:697. Var. **glabrata**, Rehd. Lfts. usually lanceolate or narrow-lanceolate, quite glabrous beneath; branchlets and petioles often purple, glabrous; stamens 2-3 times as long as petals. Cent. and W. China. This is the handsomest variety and resembles somewhat *S. Aitchisonii*. Var. **subtomentosa**, Rehd. Lfts. usually elliptic to oblong-lanceolate, densely stellate-pubescent or tomentose beneath, with close-set veins; branchlets and petioles pubescent.

AA. Lfts. simply or indistinctly doubly serrate, $\frac{1}{2}$ in. or less wide.

Aitchisonii, Hemsl. (*Spiræa angustifolia*, Zabel. *S. Aitchisonii*, Hemsl. *S. sorbifolia* var. *angustifolia*, Wenzig). Shrub, 6-8 ft. high, with upright or ascending, little-branched, glabrous sts. usually bright red when young; lfts. 15-21, lanceolate to linear-lanceolate, acuminate, narrowed at the base, simply or obscurely doubly serrate, glabrous, 2-4 in. long; panicles to 12 in. long and to 6 in. broad, with spreading ramifications, leafy at the base; fls. $\frac{1}{4}$ in. or more across. July-Sept. Afghanistan, Kashmir. G.C. III. 28:255; 38:114; 43:397. G. 27:441; 31:455; 34:639. G.M. 49:42. Gn.M. 9:75. Gn. 68, p. 143; 77, p. 560. M.D.G. 1901:18.—A very desirable shrub with handsome graceful foliage.

S. grandiflora, Maxim. (*Spiræa grandiflora*, Sweet. *Spiræa sorbifolia* alpina, Pallas). Allied to *S. sorbifolia*. One to 3 ft. high; lvs. glabrous; panicles 3-5 in. long; fls. $\frac{1}{2}$ in. across. S. Siberia. Gt. 9:295. —*S. Kirilowii*, Maxim. (*Spiræa Kirilowii*, Regel). Allied to *S. sorbifolia*. Shrub, 5-10 ft.: lfts. 12-19, glabrous; panicle broadly pyramidal; stamens as long as corolla; fr. with the style much below the apex. N. China. —*S. Millefolium*, Focke=Chamaebatiaria Millefolium.

ALFRED REHDER.

SORBUS (ancient Latin name of *S. domestica*). Including *Aria*, *Cormus*, *Micromèles*, and *Torminaria*. *Rosaceæ*. Ornamental woody plants grown for their handsome foliage, attractive white flowers and ornamental usually red fruit.

Deciduous trees or shrubs: lvs. alternate, stipulate, simple and serrate or odd-pinnate, folded or rarely convolute in the bud; fls. in compound corymbs; sepals and petals 5; stamens 15-20, with red or yellow anthers; carpels 2-5, either partly free above and half superior or wholly connate and quite inferior; styles free or connate at the base; fr. a 2-5-lobed pome, usually rather small; the cells with cartilaginous or leathery walls, each with 1 or 2 seeds. Closely allied and often referred to *Pyrus*, from which it is chiefly distinguished by its compound infl. and by the fls. being in most species more or less perigynous; the frs. are usually smaller and berry-like.—About 80 species distributed throughout the northern hemisphere, in N. Amer., south to N. C. and New Mex., in Asia south to the Himalayas. The frs. of some species, as *S. domestica*, *S. torminalis*, *S. Aucuparia* var. *dulcis* and var. *rossica* are edible and are made into preserves in Europe; the strong and close-grained wood of *S. torminalis* and *S. domestica* is used for handles of tools and for similar small articles.

The sorbuses are handsome trees or shrubs with graceful pinnate or with simple foliage sometimes silvery white beneath, and with showy clusters of small white

rarely pinkish flowers in spring, followed by red or rarely whitish or brown fruits usually berry-like, rarely larger and apple- or pear-shaped. Most of the pinnate-leaved kinds are hardy North except some Asiatic species and *S. domestica*, which seem tender north of Massachusetts; they are chiefly inhabitants of mountainous regions, and the northern species, as *S. americana* and *S. decora*, do not thrive well in warmer and drier climates, while the simple-leaved species, as *S. alnifolia*, *S. intermedia*, *S. Aria*, and *S. torminalis*, endure drought and heat well and have proved hardy at least as far north as Massachusetts. The trees are often attacked by borers. Propagation is by seeds sown in fall or stratified, also by layers. Varieties and rarer kinds are usually budded or grafted on allied species, but most kinds will grow on *S. Aucuparia* or *S. americana* and on hawthorn. They all have handsome foliage, which usually turns orange-red in fall; their fruits are showy and often remain on the branches the whole winter if not eaten by birds. They are not particular as to the soil and are well suited for planting on rocky hillsides. Those of the *Aucuparia* group are more adapted for cool and moist mountain regions; those of the *Aria* and *Torminaria* group, which grow especially well on limestone soil, are suited to warmer and drier climates. *S. hybrida* is sometimes used as a small-sized avenue tree on account of its regular pyramidal habit.

KEY TO THE SPECIES.

- A. Foliage pinnate.
- B. Lvs. regularly pinnate, with the lfts. of almost equal size.
- C. Frs. small, $\frac{1}{4}$ - $\frac{1}{2}$ in. across, or slightly larger, berry-like.
- D. Lfts. 9-17, $\frac{3}{4}$ -4 in. long.
- E. Winter buds glutinous, glabrous or sparingly appressed, rusty-pubescent.
- F. Fls. $\frac{1}{2}$ - $\frac{1}{4}$ in.: lfts. long-acuminate; fr. $\frac{1}{6}$ - $\frac{1}{4}$ in. across. 1. *americana*
- FF. Fls. $\frac{1}{4}$ - $\frac{1}{2}$ in. across: lfts. acute or obtusish; fr. about $\frac{1}{2}$ in. across. 2. *decora*
- EE. Winter buds covered with white villous tomentum.
- F. Young branchlets and lvs. pubescent. 3. *Aucuparia*
- FF. Young branchlets and lvs. glabrous. 4. *tianschanica*
- DD. Lfts. 19-29, $\frac{1}{2}$ - $\frac{3}{4}$ in. long. 5. *Vilmorinii*
- CC. Frs. $\frac{1}{2}$ in. or more across, apple- or pear-shaped, with grit-cells; styles 5. 6. *domestica*
- BB. Lvs. only pinnate toward the base, lobed or only serrate in the upper part, varying much on the same plant and occasionally only lobed. Hybrids.

- c. *Habit tree-like*..... 7. *hybrida*
 cc. *Habit shrub-like*..... 8. *spuria*
 AA. *Foliage simple*.
 B. *Fr. with persistent calyx*.
 c. *Under side of lvs. glabrous at length, green; lvs. lobed; ovary inferior; fr. brown, with gricells*..... 9. *torminalis*
 CC. *Under side of lvs. grayish or whitish tomentose; ovary half-superior*.
 D. *Lvs. lobed or sharply serrate*.
 E. *Shape of lvs. ovate to oblong, usually acute*.
 F. *Margin of lvs. lobed*.
 G. *Base of the usually broadly ovate lvs. mostly rounded*..... 10. *latifolia*
 GG. *Base of the ovate to oblong-ovate lvs. broadly cuneate*..... 11. *intermedia*
 FF. *Margin of lvs. sharply and doubly serrate*..... 12. *Aria*
 EE. *Shape of lvs. suborbicular to broadly obovate*..... 13. *umbellata*
 DD. *Lvs. serrulate, grayish-tomentose or sometimes glabrescent beneath*..... 14. *alpina*
 BB. *Fr. with deciduous calyx leaving a circular scar; ovary quite inferior*.
 c. *Under side of lvs. glabrous or slightly pubescent*.
 D. *Styles usually 2; lvs. ovate to elliptic-ovate*..... 15. *alnifolia*
 DD. *Styles usually 5; lvs. elliptic-oblong to obovate-oblong*..... 16. *caloneura*
 CC. *Under side of lvs. white-tomentose*. 17. *Folgneri*

Group 1. AUCUPARIA.

1. *americana*, Marsh. (*Pyrus americana*, DC. *S. micrantha*, Dum.-Cours.). AMERICAN MOUNTAIN-ASH. DOGBERRY. Fig. 3648. Small tree, attaining 30 ft., with spreading branches, or sometimes shrubby: lfts. 11-17, lanceolate, long-acuminate, sharply serrate, glabrous or slightly pubescent when young, light green above, paler beneath, $1\frac{1}{2}$ -4 in. long: fls. $\frac{1}{2}$ - $\frac{3}{4}$ in. across, in dense, 3-6-in.-broad, usually glabrous corymbs: fr. globose, bright red, $\frac{1}{6}$ - $\frac{1}{4}$ in. across, with the calyx-lobes very small and connivent. May, June. Newfoundland to Man., south to Mich. and N. C. S.S. 4:171, 172. F.E. 23:209; 32:721. Var. *microcarpa*, Torr. & Gray (*S. microcarpa*, Pursh), has narrower foliage and very small frs. about $\frac{1}{2}$ in. across.

3648. *Sorbus americana*. ($\times\frac{1}{2}$)

2. *decora*, Schneid. (*S. americana* var. *decora*, Sarg. *Pyrus sambucifolia*, Gray, not Cham. & Schlecht. *Pyrus stichensis*, Rob. & Fern., not Piper. *S. scopulina*, Brit., not Greene). Small tree or shrub, closely allied to the preceding: lfts. 7-15, oval to ovate-lanceolate, or oblong, obtuse to short-acuminate, serrate, glabrous and

3649. *Sorbus Aucuparia*. ($\times\frac{1}{2}$)

dark green above, rather pale and usually pubescent beneath when young, or glabrous, $1\frac{1}{2}$ -3 in. long: fls. $\frac{1}{4}$ - $\frac{1}{2}$ in. across, in 2-4-in.-broad and rather loose corymbs, sometimes few-flid.: fr. globose, ovoid when young, red, about $\frac{1}{2}$ in. across, with more or less upright calyx-lobes. May. Labrador to Minn., south to N. Y. and Vt. S.S. 4:173, 174.—Often confounded with the preceding species; intermediate forms are not uncommon in regions where the two meet. Both are very handsome in autumn with their large clusters of bright red fr. and particularly *S. decora* is often planted for its showy fr.

3. *Aucuparia*, Linn. (*Pyrus Aucuparia*, Gaertn.). EUROPEAN MOUNTAIN-ASH. ROWAN TREE. Fig. 3649. Round-headed tree, 20-40, occasionally 60 ft. high: young branchlets pubescent, grayish brown when older: petioles more or less tomentose; lfts. 9-15, oblong to oblong-lanceolate, serrate, entire toward the base, dull green above, pubescent beneath or rarely glabrous, $\frac{3}{4}$ -2 in. long: fls. white, $\frac{1}{2}$ in. across, in flat, 4-6-in.-broad, tomentose or sometimes almost glabrous corymbs; stamens about as long as petals: fr. globose, about $\frac{1}{2}$ in. across, bright red. May, June. Eu. to W. Asia and Siberia. H.W. 3:54, pp. 78, 79. Var. *dulcis*, Kraetzel (var. *moravica*, Zengerling). Almost glabrous: petioles purplish; lfts. oblong-lanceolate, 2-3 in. long, glaucescent beneath, usually serrate only above the middle. The frs. are of an agreeable acid flavor and recommended for preserves. The tree thrives well in cold northern climates where hardly any other fr.-tree will grow. G.M. 52:887. Var. *rossica*, Spaeth, is similar and also bears edible fr., but the lfts. are larger and broader and more serrate. Var. *Beissneri*, Rehd. (var. *dulcis laciniata*, Beissn., not var. *laciniata*, Hartm.), is a handsome and graceful form of var. *dulcis* with the lfts. pinnately lobed and the lf.-stalks and young branchlets bright red. G.W. 3:267. Var. *fastigiata*, Loud., forms a narrow pyramidal tree, with upright branches. Var. *pendula*, Hort., has long and slender pendulous branches. M.D. 1911, p. 246. Var. *integerrima*, Lange. Lfts. entire or nearly so. Var. *Fifeana*, Dipp. (var. *fructuliteo*, Hort.). Fr. yellow. There are also varieties with

variegated foliage.—This species is often planted as a street tree in mountain regions of Eu.

4. *tianschânica*, Rupr. (*Pyrus thianschânica*, Regel). Small tree or shrub, similar to the preceding: young branchlets glabrous, red-brown and glossy when older: petioles and lvs. glabrous; lfts. 11–15, lanceolate,

3650. *Sorbus domestica*. ($\times \frac{1}{2}$)

acuminate, serrate, entire toward the base, dark green and glossy above, light green beneath, about 2 in. long: corymbs glabrous; stamens half as long as petals; styles 2–5; fr. globose, bright red. May, June. Cent. Asia. Gt. 40, p. 8. B. M. 7755.—Very handsome on

account of the contrast of its dark green foliage and red-brown branches.

5. *Vilmorinii*, Schneid. (*Cormus foliolosa*, Franch.). Shrub or small tree, to 20 ft.: lvs. slender; rachis slightly winged; lfts. 19–29, opposite or nearly so, oblong-elliptic, serrate above the middle, glabrous, $\frac{1}{2}$ – $\frac{3}{4}$ in. long; infl. loose, 1–3 in. wide, rusty-pubescent; fls. $\frac{1}{4}$ in. across; stamens about 20; styles 3, nearly glabrous; fr. globose, red, $\frac{1}{2}$ in. across. June; fr. in Sept. W. China. B.M. 8241.—A very graceful shrub.

Group 2. CORMUS.

6. *domestica*, Linn. (*Pyrus Sôrbus*, Gaertn. *P. domestica*, Smith. *Cormus domestica*, Spach). SERVICE TREE. Fig. 3650. Round-headed tree, 30–60 ft. high: winter buds glutinous: petioles tomentose; lfts. 11–17, obovate-oblong to oblong, sharply and rather coarsely serrate, with acuminate teeth, usually entire near the base, green and glabrous above, floccose-tomentose beneath, at least when young, 1–2½ in. long: fls. white, $\frac{1}{2}$ in. across, in broadly pyramidal rather loose, tomentose corymbs: fr. $\frac{1}{2}$ –1¼ in. across, usually yellowish, with red or orange cheek, apple-shaped in var. *maliformis*, Lodd., pear-shaped in var. *pyriformis*, Lodd. May. S. Eu., N. Afr., and W. Asia. G.C. II. 1:283; 6:649. M.D.G. 1897:376–8. H.W. 3, pp. 80, 81. G.W. 1, p. 158.—This species is often confounded with the European mountain-ash, from which it is almost indistinguishable without frs. or fls., except by the glutinous winter buds.

Hybrids of Group 1 with Group 4 or with Aronia.

7. *hybrida*, Linn. (*Pyrus pinnatifida*, Ehrh. *P. fenica*, Babington. *S. intermedia* $\times$ *S. Aucuparia*). Tree, attaining 40 ft., of regular, pyramidal habit, with upright branches: young branchlets and petioles whitish tomentose: lvs. ovate to oblong-ovate, with 1–4 pairs of decurrent lfts. at the base, or but pinnately lobed, upper part lobed with the lobes becoming gradually shorter and more indistinct toward the apex, dark green above, whitish or grayish tomentose beneath, 2½–5 in. long; petioles about 1 in. long: fls. $\frac{1}{2}$ –¾ in. across, in tomentose corymbs about 3 in. broad: fr. globose-ovoid, ½ in. high. May, June. H.W. 3, p. 86. S.I.F. 3:485.—A form of narrow pyramidal habit is var. *fastigiata*, Hort. G.C. III. 42:185.—Natural hybrid, occasionally found with the parents in Eu. Two different hybrids are usually included under *S. hybrida*; the typical one is *S. Aucuparia* $\times$ *S. intermedia*, which has the lvs. oblong-ovate to oblong, 3–5 in. long, with 10–12 pairs of veins, the lfts. and lobes narrower and pointed and the veins often slightly recurved. It is mostly cult. under the name of *S. quercifolia*, or *S. quercoides*, Hort. The

second hybrid is var. *thuringiaca*, Rehd. (*Pyrus thuringiaca*, Ilse. *S. thuringiaca*, Schneid.), and is a hybrid of *S. Aucuparia* $\times$ *S. Aria*; it has ovate to ovate-oblong lvs., somewhat less deeply lobed, 2½–4 in. long, with 8–10 pairs of veins, lfts. and lobes broader and obtusish, with the veins usually curving upward. This is known in gardens as *S. quercifolia hybrida nana*. Var. *decurrens*, Koehne (*S. decurrens*, Hedl. *S. lanuginosa*, Hort., not Kit.), is a transition to *S. Aucuparia*; only the 3 or 5 upper lfts. are connate into a terminal lft., which, like the upper separate lfts., is decurrent at the base, under side less densely tomentose. In some nurseries under the name of *S. sambucifolia*.

8. *spuria*, Pers. (*Pyrus heterophylla*, Dur. *S. Aucuparia* $\times$ *Aronia arbutifolia*). Shrub or small tree, attaining 15 ft., with slender, sometimes pendulous branches: lvs. ovate to oblong-ovate, obtuse, with 2–6 lobes or lfts. near the base, simply crenate-serrate toward the apex, 1½–3½ in. long, pubescent beneath: fls. white or pinkish white, in pubescent or glabrous corymbs 1–1½ in. broad: fr. subglobose or pear-shaped, dark purple. May, June. Of garden origin. B.R. 1196.—Sometimes cult. under the name *S. quercifolia floribunda nana*. Hybrids of different origin are usually united under *S. spuria*; the more pubescent forms with dark purple fr. are probably the offspring of *S. Aucuparia* and *Aronia arbutifolia* and represent typical *S. spuria*, while the more glabrous forms with usually blackish fr. have *S. Aucuparia* and *Aronia melanocarpa* as their parents and may be called *S. fallax*, Schneid. (*S. heterophylla*, Dipp.). A similar form with quite glabrous and more pointed lvs., is probably a hybrid of *S. americana* and *Aronia melanocarpa*, and is named *S. sorbifolia*, Hedl. (*S. Sargentii*, Dipp.).

Group 3. TORMINARIA.

9. *torminalis*, Crantz (*Pyrus torminalis*, Ehrh. *Torminaria torminalis*, Dipp. *T. Clusii*, Roem.). WILD SERVICE TREE. Round-headed tree, with spreading branches, 40–80 ft. high: lvs. broadly ovate, slightly cordate to broadly cuneate at the base, with several triangular-ovate, serrate lobes on each side, the lower sinuses reaching about half-way to the middle, floccose-tomentose when young, finally glabrous, rarely with persistent tomentum, 2–4 in. long; petioles 1–1¾ in. long: fls. white, ½ in. across, in broad, rather loose tomentose corymbs: fr. oval, ½–¾ in. high, brown, dotted. May, June. S. and Cent. Eu. H.W. 3:53, pp. 82, 83.—The foliage turns bright red in autumn.

Group 4. ARIA.

10. *latifolia*, Pers. (*Pyrus rotundifolia*, Bechst. *P. intermedia* var. *latifolia*, Ser. *P. Aria* var. *latifolia*, Hort. *Torminaria latifolia*, Dipp. *S. Aria* $\times$ *S. torminalis*). Tree, attaining 50 ft., similar to the preceding: lvs. broadly ovate to ovate, usu-

3651. *Sorbus Aria*. ($\times \frac{1}{2}$)

ally rounded at the base, pinnately lobed with short, broadly triangular, sharply serrate lobes, and with 6-9 pairs of veins, grayish or whitish tomentose beneath, $2\frac{1}{2}$ -4 in. long; petioles $\frac{1}{2}$ -1 in. long; fls. about $\frac{1}{2}$ in. across, in broad, tomentose corymbs: fr. globose or globose-ovoid, about $\frac{1}{2}$ in. high, orange to brownish red. May, June. Occasionally occurring in Cent. Eu. H. W. 3, p. 85.

11. *intermedia*, Pers. (*Pyrus intermedia*, Ehrh. *Sorbus scindica*, Fries. *Äria suecica*, Koehne. *Hähnna suecica*, Dipp.). Tree, 20-40 ft. high, with oval head: lvs. ovate to oblong-ovate, broadly cuneate at the base, pinnately lobed with broad and short, irregularly serrate lobes and 5-8 pairs of veins, whitish tomentose beneath, $2\frac{1}{2}$ -4 in. long; petioles $\frac{1}{2}$ - $\frac{3}{4}$ in. long; fls. about $\frac{1}{2}$ in. across, in broad, tomentose corymbs: fr. orange-red, globose or subglobose, about $\frac{1}{2}$ in. high. May. N. and Cent. Eu. S.I.F. 3:485.—This is sometimes confounded with *S. hybrida* and considered to be a hybrid of similar origin, but it is certainly a good species. It never bears distinct lfts. at the base and the sinuses do not reach farther than one-third toward the middle.

12. *Äria*, Crantz (*Pyrus Äria*, Ehrh. *Äria nivea*, Host. *Hähnna Äria*, Medikus). WHITE BEAM-TREE. Fig. 3651. Tree, with broadly pyramidal or oval head, 25-50 ft. high: lvs. elliptic to oblong-oval, usually cuneate at the base, acute or obtuse at the apex, sharply and doubly serrate, of firm texture, bright or dark green and glabrous above, white-tomentose beneath, 2-5 in. long; petioles $\frac{1}{2}$ - $\frac{3}{4}$ in. long; fls. $\frac{1}{2}$ - $\frac{3}{4}$ in. across, in tomentose, 2-3-in.-broad corymbs: fr. subglobose, orange-red, about $\frac{1}{2}$ in. high. May. Cent. and S. Eu. to Himalayas and Siberia. G.M. 44:291. H.W. 3:52.—Desirable tree for dry and exposed situations, and very ornamental in foliage on account of the contrasting colors of the upper and under sides of the lvs. Var. *Decaisneana*, Rehd. (*Äria Decaisneana*, Lav. *Pyrus Decaisneana*, Nichols. *Pyrus Äria* var. *majestica*, Prain. *S. Äria* var. *majestica*, Zabel). Lvs. elliptic or ovate, irregularly doubly serrate, 3-7 in. long; infl. 3-4 in. across; fls. $\frac{3}{4}$ in. across; stamens longer than styles: fr. oval, $\frac{1}{2}$ in. across. B.M. 8184. Origin unknown, probably from the Himalayas. Var. *edulis*, Wenzig (*Pyrus edulis*, Willd. *S. longifolia*, Hedl.). Lvs. elliptic-oblong to oblong, rounded or acute at the apex, 2-5 in. long; fr. oval, $\frac{1}{2}$ - $\frac{3}{4}$ in. high. There are some garden forms, as vars. *aurea*, *chrysophylla*, and *lutescens*, Hort., with more or less yellow foliage.

13. *umbellata*, Fritsch (*S. meridionalis*, Guss. *S. flabellifolia*, S. Schau. *S. Äria* var. *flabellifolia*, Wenzig. *S. flabellata*, Hort.). Small tree, attaining 20 ft.: lvs. orbicular to broadly oval, obtuse, usually broadly cuneate at the base, incisedly lobed above the middle, with the short lobes truncate or rounded and coarsely toothed, with 5-7 pairs of veins, snowy white beneath, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. long; fls. scarcely $\frac{1}{2}$ in. across, in dense, white-tomentose corymbs: fr. depressed-globose, orange-red. S. E. Eu., W. Asia.—Cult. in some nurseries as *Pyrus aurea striata*. Var. *cretica*, Schneid. (*S. Äria* var. *cretica*, Rehd. *Äria græca*, Roem. *S. Äria* var. *græca*, Koch). Lvs. orbicular-obovate, doubly serrate, scarcely lobed, with 6-11 pairs of veins, $1\frac{1}{2}$ -3 in. long. S. E. Eu., W. Asia.

14. *alpina*, Heynh. (*Arónia densiflora*, Spach. *A. Willdenowii*, Zabel. *S. Äria* x *Arónia arbutifolia*). Shrub, similar to *S. Äria*, but lvs. smaller, densely serrulate, with fewer and less straight veins: infl. and fls. smaller; styles 3-4: fr. red or brownish red, $\frac{1}{4}$ in. across. Of garden origin.—From *Arónia arbutifolia* it may be distinguished by usually larger lvs. with more numerous veins and with a less close and less glandular serration and by larger fls. with only 3-4 styles. A similar hybrid is *S. Dippelii*, Zabel (*S. Äria* x *Arónia melanocarpa*) with the lvs. often finally glabrescent and black frs. over $\frac{1}{2}$ in. across.

Group 5. MICROMELES.

15. *alnifolia*, Koch (*Micromèles alnifolia*, Koehne. *Pyrus Miyabei*, Sarg.). Fig. 3652. Tree, to 60 ft., with upright branches: branchlets glabrous or slightly pubescent: lvs. ovate to elliptic-ovate, rounded at the base, short-acuminate, unequally serrate, glabrous above, glabrous or slightly pubescent beneath, on vigorous shoots sometimes densely pubescent, 2-4 in. long, with 6-10 pairs of veins: infl. loose, nearly glabrous, 6-12-fld.: fls. $\frac{1}{8}$ - $\frac{1}{2}$ in. across; ovary usually 2-celled: fr. subglobose, $\frac{1}{4}$ in. across, red with yellow. May; fr. in Sept., Oct. Cent. China, Manchuria, Korea, Japan. B.M. 7773. G.F. 7:84 (adapted in Fig. 3652). Gt. 41, pp. 283, 284; 52, p. 3. S.I.F. 1:49.

16. *caloneura*, Rehd. (*Micromèles caloneura*, Stapf. *Pyrus caloneura*, Veitch). Shrub or small tree, to 20 ft.: branchlets glabrous: lvs. elliptic-oblong to obovate-oblong, acute or sometimes short-acuminate, broadly

3652. *Sorbus alnifolia*. ($\times \frac{1}{2}$)

cuneate at the base, doubly crenate-serrate, quite glabrous and dark green above, pale beneath and sparingly hairy on the veins, $2\frac{1}{2}$ -3 $\frac{1}{2}$ in. long, with 10-12 pairs of veins impressed above: infl. dense, many-fld.: fls. $\frac{1}{4}$ in. across, with violet-purple stamens; styles 5; ovary 5-celled: fr. pyriform, $\frac{1}{8}$ - $\frac{1}{2}$ in. long, brown. May; fr. in Oct. Cent. China. B.M. 8335.

17. *Fölgneri*, Rehd. (*Micromèles Fölgneri*, Schneid. *Pyrus Fölgneri*, Bean). Tree with spreading and arching branches: young branchlets tomentose: lvs. ovate to elliptic-ovate, acute or short-acuminate, rounded or broadly cuneate at the base, finely serrate or on shoots doubly serrate and often slightly lobed, dark green and glabrous above, white-tomentose beneath, 2-3 in. long, with 8-9 pairs of veins: infl. about 4 in. across, tomentose, many-fld.; fls. $\frac{1}{4}$ - $\frac{1}{2}$ in. across; styles 3: fr. ovoid, red, about $\frac{1}{2}$ in. long. May; fr. in Oct. Cent. China. M.D.G. 1912:136. Var. *péndula*, Rehd. (*Pyrus Fölgneri* var. *péndula*, Veitch). Branches pendulous.—This is a very handsome and graceful species.

S. aperta, Koehne. Allied to *S. Aucuparia*. Tree, to 40 ft.: lfts. 9-17, elliptic to elliptic-oblong, acute, serrate, glabrous, 1-2 in. long; styles 5; fr. small, whitish. W. China.—*S. arbutifolia*, Heynh.—*Aronia arbutifolia*.—*S. Chamæspilus*, Crantz (Pyrus Chamæspilus, Poll. P. alpina, Dur. *Aria* Chamæspilus, Host.). Upright shrub, 6 ft. high, allied to *S. Aria*. Lvs. elliptic to oblong, serrate, almost glabrous, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long; fls. pinkish, with upright petals, in dense corymbs about $1\frac{1}{2}$ in. broad; fr. oval, orange to brownish red. Cent. and S. Eu. H.W. 3, p. 84. Var. *sudetica*, Wenzig. Lvs. whitish or grayish tomentose beneath. Mountains of Cent. Eu.—*S. commixta*, Hedl. (*S. Aucuparia* var. *japonica*, Maxim.). *S. japonica*, Koehne, not Hedl.). Allied to *S. americana*. Small tree: lfts. 11-15, oblong-lanceolate to lanceolate, long-acuminate, glabrous, 2-3 in. long; infl. glabrous; fr. red, small. Japan. S.I.F. 2:31.—*S. Conradina*, Koehne. Allied to *S. Aucuparia*. Tree, to 25 ft.: stipules large, persistent; lfts. 11-13, oblong to oblong-lanceolate, short-acuminate, serrate, tomentose beneath, 2-3 in. long; styles usually 4; fr. globose, red, about $\frac{1}{2}$ in. across. W. China.—*S. cuspidata*, Hedl. (*S. vestita*, Schau. Pyrus *vestita*, Wall. Pyrus *crenata*, Lindl., not Don. *Cornus lanata*, Koehne. *S. nepalensis*, Hort.). Tree, allied to *S. Aria*; lvs. elliptic to elliptic-oblong, acuminate, doubly serrate, densely tomentose beneath, 3-7 in. long; styles usually 5, woolly at the base; fr. about $\frac{1}{2}$ in. across. Himalayas. G.C. II. 1:17. B.M. 8259.—*S. Decaisneana*, Rehd. (*Micromeles Decaisneana*, Schneid.). Tree, to 40 ft.: lvs. elliptic-obovate, crenate-serrulate, with 8-10 pairs of veins, nearly glabrous beneath, 2-3 $\frac{1}{2}$ in. long; infl. tomentose, $1\frac{1}{2}$ in. across; styles usually 3, connate below; fr. ovoid, red, $\frac{1}{2}$ in. across with deciduous calyx. Cent. and W. China.—*S. discolor*, Hedl. (*Pyrus discolor*, Maxim.). Doubtful species allied to *S. Aucuparia*; possibly the same as *S. pekinensis*. The plants in cult. as *S. discolor* probably do not belong here.—*S. Essertiana*, Koehne. Allied to *S. Aucuparia*. Tree, to 25 ft.: stipules large, persistent; lfts. 11-13, oblong-lanceolate, subacuminate, serrate, whitish tomentose beneath, $1\frac{1}{2}$ - $3\frac{1}{2}$ in. long; infl. tomentose, 4-6 in. across; fr. globose, scarlet, $\frac{1}{2}$ in. across. W. China.—*S. gracilis*, Koch (Pyrus *gracilis*, Sieb. & Zucc.). Shrub, with pinnate lvs., those at the base of the loose, few-fl. corymbs with large, incised-dentate stipules: lfts. 7-9, ovate to ovate-oblong, 1-1 $\frac{1}{2}$ in. long; styles 2. Cent. and Japan.—*S. Hostii*, Koch (Pyrus *Hostii*, Hemsl. *Aria* *Hostii*, Jacq. f.). Supposed to be a hybrid between *S. Mougeotii* and *S. Chamæspilus*: shrub or small tree, 12 ft. high; lvs. oval to elliptic-obovate, sharply serrate; fls. pinkish, in dense corymbs about $2\frac{1}{2}$ in. broad; fr. globose, ovoid, red. Mountains of Cent. Eu. Gn. 20:376. R.H. 1877:210.—*S. japonica*, Hedl. (*Micromeles japonica*, Koehne. *S. Koehnei*, Zabel). Allied to *S. alnifolia*. Lvs. pubescent above, grayish tomentose beneath; infl. denser with smaller fls.: fr. deeper scarlet, punctate. Japan. S.I.F. 1:48.—*S. japonica*, Koehne= *S. commixta*.—*S. japonica*, Zabel=Eriobotrya *japonica*.—*S. Koehnei*, Zabel (not to be confused with *S. Koehneana*, Schneid., a species of the *Aucuparia* group, not in cult.). *S. japonica*,—*S. lanata*, Wenzig (Pyrus *lanata*, Don). Tree, allied to *S. Aria*; lvs. oval, sharply and doubly serrate and slightly lobed, 4-7 in. long; styles 2-3, connate below, woolly; fr. globose, $\frac{1}{2}$ - $1\frac{1}{2}$ in. across. Himalayas.—*S. Matsumurana*, Koehne (Pyrus *Matsumurana*, Makino). Allied to *S. decora*. Shrub, glabrous: lfts. 9-13, oblong-ovate to oblong, acute, serrate above the middle, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long; stamens half as long as petals; styles 5; fr. red, $\frac{1}{2}$ in., bloomy. Japan.—*S. megalocarpa*, Rehd. Shrubby tree, to 25 ft.: lvs. elliptic-obovate to obovate-oblong, acuminate, crenate-serrate, glabrous, 5-10 in. long; infl. 4-6 in. across; styles usually 3; fr. $\frac{1}{2}$ -1 in. long, russet-brown. W. China.—*S. meliosmifolia*, Rehd. Allied to *S. alnifolia*. Tree, to 30 ft.: lvs. short-petioled, ovate to elliptic-oblong, doubly serrate, with 13-24 pairs of veins, slightly pubescent beneath, 5-8 in. long; infl. 2-4 in. across; fr. subglobose, brownish red, $\frac{1}{2}$ in. long. W. China.—*S. Mougeotii*, Soyer-Willemet (Pyrus *Mougeotii*, Aschers. & Graebn.). Allied to *S. intermedia*; often shrubby; lvs. ovate to ovate-oblong, lobed, short-acuminate, with 8-12 pairs of veins; fr. red, globose, $\frac{1}{2}$ in. across, edible. Mountains of Cent. Eu. H.W. 3, p. 83.—*S. nepalensis*, Hort.—*S. cuspidata*.—*S. occidentalis*, Greene= *S. pumila*.—*S. ochrocarpa*, Rehd. Allied to *S. Aria*. Lvs. generally elliptic, doubly denticulate-serrate, glabrous, 13-17, oblong, acute, 1 $\frac{1}{2}$ -2 in. long; infl. small, sessile, styles 2, connate at base; fr. pale, subglobose, $\frac{1}{2}$ in. across. W. China.—*S. pekinensis*, Koehne. Allied to *S. americana*. Tree, nearly glabrous: lfts. 13-17, oblong, acute, serrate, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long; infl. 4-8 in. across; styles 3; fr. subglobose, small, pinkish white or yellowish. N. China. Gt. 55:1551, fig. 7.—*S. pohuashanensis*, Hedl. Allied to *S. Aucuparia*. Tree: stipules large, persistent; lfts. 13-15, ovate-oblong to ovate-lanceolate, whitish beneath, $1\frac{1}{2}$ -2 in. long; infl. 4-5 in. across, tomentose; fr. red, subglobose, $\frac{1}{2}$ in. across. N. China.—*S. pumila*, Raf. (*S. sitchensis*, Roem. *S. occidentalis*, Greene. *S. sambucifolia* var. *Gravi*, Wenzig). Allied to *S. decora*. Shrub: lfts. 7-11, oval to oval-oblong, obtuse, serrate toward the apex, bluish green, 1-2 in. long; infl. 1-3 in. across; styles 3-5; fr. subglobose, red. Alaska to N. Calif. G.F. 10:85.—*S. sambucifolia*, Roem. Allied to *S. americana*. Shrub: lfts. 9-11, ovate-oblong, acuminate, serrate, glabrous, green on both sides, 2-3 in. long; infl. slightly villous; fr. subglobose, $\frac{1}{2}$ in. across, yellowish red. N. E. Asia. Very rare in cult., usually *S. decora* is cult. under this name.—*S. Sargentiana*, Koehne. Allied to *S. Aucuparia*. Tree, to 30 ft.: stipules large, persistent; lfts. 9-11, oblong-lanceolate, acuminate, serrate, villous beneath while young; infl. 6 in. across; styles 3-5; fr. globose, $\frac{1}{2}$ in. across, scarlet. W. China. Not to be confused with *S. Sargentii* which see under No. 3.—*S. scalaris*, Koehne. Allied to *S. Vilmosinii*. Shrub, to 20 ft.: stipules large, persistent; rachis slightly winged; lfts. 25-27, linear-oblong, dentate only at the apex, villous beneath, $\frac{1}{4}$ - $1\frac{1}{2}$ in. long; infl. tomentose; styles 3-4; fr. globose, red, $\frac{1}{2}$ in. across. W. China.—*S. setschuanensis*, Koehne. Allied to *S. Vilmosinii*. Shrub, to 15 ft.: rachis slightly winged; lfts. 25-35, narrow-oblong, serrulate, glabrous, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; infl. glabrous, 1-2 $\frac{1}{2}$ in. across; styles 2-4;

fr. globose, $\frac{1}{2}$ in. across, whitish or pale purple. W. China.—*S. sitchensis*, Roem.= *S. pumila*.—*S. sudetica*, Heynh.= *S. Chamæspilus* var. *sudetica*.—*S. unguiculata*, Koehne. Allied to *S. Vilmosinii*. Shrub, to 15 ft.: rachis narrowly winged; lfts. 23-33, oval to narrow-oblong, serrulate, villous on midrib beneath, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; infl. 1-2 in. broad, slightly villous; claw or petals one-half as long as blade; fr. globose, $\frac{1}{2}$ in. across, whitish or pale purple. W. China.—*S. vestita*, Wall.= *S. cuspidata*.

ALFRED REHDER.

SORGHÁSTRUM (named for its resemblance to sorghum, a name which has been applied to *Holcus*). *Gramineæ*. Grasses having the infl. as in *Holcus* but the pedicellate spikelet wanting, the pedicel only present.—Species about 12, mostly American.

nütans, Nash (*Chrysopogon nütans*, Benth. *Andropogon avenaceus*, Michx.). INDIAN GRASS. In large clumps, perennial, 3-5 ft. tall, bearing beautiful narrow panicles, 6-12 in. long, the copious golden hairs and brilliant yellow anthers producing a charming effect when in bloom, turning to a bronzy brown; culms simple, lvs. pale. A native species occurring on dry soils from the Atlantic to the Rocky Mts. Dept. Agric., Div. Agrost. 7:21. f. 15. 1897.—Useful for the wild border. One of the handsomest natives; very hardy and worthy of greater use.

A. S. HITCHCOCK.

SORGHUM: *Holcus*.

SORINDEIA (said to be the native name in Madagascar). *Anacardiaceæ*. Glabrous trees or shrubs, suitable for the warmhouse and also grown outdoors in the far South.

Leaves alternate, odd-pinnate; the lfts. entire: fls. small, polygamous or dioecious, in many-fl. panicles which are terminal, axillary, or from the old wood, often lax and divaricate; calyx 4-5 (3)-toothed, cup-shaped; petals as many as the calyx-teeth, valvate; stamens in the male fl. 10-20, occupying a central disk or as many or twice as many as the petals, inserted around the disk; ovary in the female fl. sessile; fr. drupaceous.—About 15 species, Trop. Afr. and Madagascar.

madagascariensis, DC. GRAPE MANGO. Tree, often of large size, glabrous: lvs. odd-pinnate, more or less leathery; lfts. 7-9-11, oblong or oblong-elliptical, the terminal often obovate; panicles fascicled, lateral, or from the old wood, often 1-2 ft. long, dependent in fr., calyx broadly 5-toothed: fr. the size of a "sparrow's egg," yellow, "sweet, with the taste of turpentine." Madagascar, Trop. E. Afr., and Zanzibar.—Cult. in Trop. Asia and intro. into the southern U. S.

F. TRACY HUBBARD.

SORREL. Various species of *Rumex* (which see) produce large thick acid leaves which are prized for salads or for "greens." Leaves of some of the native or naturalized species are gathered as pot-herbs in many parts of the country. In the Old World, however, several species are regularly cultivated in kitchen-gardens; in this country these cultivated species are relatively little known. They are perennials of the very easiest culture. Usually they persist for a number of years after well established, giving an abundance of soft edible leaves early in the spring when herbage is scarce. They are usually grown from seeds, and plants fit for cutting may be had when the plants are one or two years old. Plants should be placed at one side of the garden where they will not interfere with the regular tillage. No special treatment is demanded. When they begin to show signs of failing, new plants should be started or the old ones may be taken up and divided. The rows should stand about 18 inches apart. Do not let the plants exhaust themselves by seed-bearing. The spinach dock (*Rumex Patientia*) is one of the best and earliest. The bellefeuille (*Rumex Acetosus*) is also an excellent plant for the home-garden and has the advantage of following the other as a succession. Various other species may be had of European seed-dealers. See *Dock* and *Rumex*.

L. H. B.

SORREL-TREE: *Oxydendrum*. S., Wood: *Oxalis Acetosella*.

SOUR GUM: *Nyssa sylvatica*. S. Sop: *Annona muricata*. S. Wood: *Oxydendrum*.

SOUTHERNWOOD (*Artemisia Abrotanum*, which see for botanical account) is a European herb, aromatic, much branched, woody-stemmed, rather tender, perennial, 3 to 5 feet tall, with pale green or grayish often variegated leaves, small yellowish flowers and minute seeds. (Fig. 3653.) It is occasionally found in family gardens, where it is grown from seed (or more often from its easily rooted cuttings, which are most readily obtained in early summer) for its pleasant taste and tonic properties, which resemble those of wormwood. It is seldom offered by seedsmen in this country because of its slight importance.

M. G. KAINS.

SOWBUGS. There are two common species, *Armadillidium vulgare* and *Porcellio laevis*, known respectively as the greenhouse pillbug and the doorway sowbug. These are small oval grayish terrestrial crustaceans (not insects) that live in damp situations. They feed, mostly at night, on decaying vegetable matter and sometimes attack germinating seeds and the roots, crown, and occasionally the leaves and blossoms of greenhouse plants, such as primulas, petunias, saxifrage, violets, geraniums, roses, and wisteria. Orchids, especially cattleyas, are liable to injury. Head lettuce is often infested, and sowbugs sometimes become a veritable pest in mushroom cellars.

Sowbugs reproduce by means of eggs which are carried by the female in a pouch on the under side of the body. The young are similar in form to the adults and are carried by the female until they attain a considerable size. There is probably but one brood annually.

Sowbugs are destroyed in greenhouses and similar situations by the use of freshly sliced potatoes or beets dusted lightly with paris green or some other arsenical. These baits should be placed on the soil near the plants to be protected in the evening, since sowbugs are nocturnal in their habits. Another excellent bait is made as follows: To a quart of corn-meal add enough brown sugar to sweeten it, then add two tablespoonfuls of paris green and stir until it is thoroughly mixed. Moisten the mixture with just enough water so that it will hold together. This bait is to be distributed around the plants as recommended above.

Water-cress sowbugs (*Mancasellus brachyurus*).—In the eastern United States water-cress is often seriously injured by an aquatic species of sowbug that attacks the submerged portions of the plant, cuts off the roots and stems, and causes large masses of the cress to float on top of the water. This form differs from the species found in greenhouses by having longer legs and antennae and being shrimp-like in form when viewed from the side. It is about $\frac{1}{2}$ inch in length and gray in color. It often occurs in immense numbers so as practically to destroy the whole crop. Where cress is grown in natural streams or ponds no practical method of controlling the sowbugs has been devised. Some growers, however, have been able to overcome the difficulty by growing the plants in broad shallow beds sloping toward the center, where a trough 10 inches square, lined with boards, extends the whole length of the bed. When the sowbugs become abundant, the water is shut off for twelve to twenty-four hours, allowing the beds to drain. Water is retained in the trough in which the sowbugs soon accumulate in great numbers. They may be destroyed by the addition of a liberal quantity of copper sulfate solution. Less injury will result to the plants if the water is drained off soon after the cress has been gathered.

C. R. CROSBY.

M. D. LEONARD.

SOW THISTLE: A name for the prickly weedy species of *Sonchus*.

SOYBEAN (*Glycine Soja*, formerly called *G. hispida*) is a legume, long a staple crop in Japan, but somewhat recently cultivated more or less extensively in the United States. (Figs. 479, 483.) In its native country, Japan, the seed is an important human food product,

but in the United States its principal use at present is as a forage plant for farm live-stock and as a soil-renovator. It is an upright leafy branching plant, growing 3 to 4 feet high. Two distinct plants have been called soybean: the smaller one (*Phaseolus aureus*) is grown principally in southern Asia; the larger species, the true soybean, is *Glycine Soja*. This latter species has become popular in some sections of the United States because of its power of resisting drought

3653. Southernwood. ($\times \frac{1}{2}$)

and for the further reason that it may supply a large amount of forage rich in protein. In the northern states it is probable that the soybean will be acclimated and that it will serve as an adjunct to the maize crop as a food for stock, although it is coarse in leaf and stalk.

It thrives best upon a warm well-drained loamy soil, and seed should not be planted until all danger from frost is over. The land should be prepared by plowing and harrowing in the early spring, and the harrow should be used two or three times before the seeds are planted. Best success is attained by planting in drills, rows to be from $2\frac{1}{2}$ to 3 feet apart and the hills in the row 18 to 20 inches apart. During the early periods of growth, cultivation should be frequent, preferably with a fine-toothed implement. After the plants have grown so that the ground is well shaded, the tillage may be discontinued. It is doubtful whether the curing of the plants for hay will ever come into general practice, but the crop may be largely grown for green soiling and for ensilage purposes. It may be cut into the silo with corn and serves to improve the quality of the food.

To the horticulturist the soybean is valuable chiefly as a soil-renovator. The soil of the orchard can be given clean culture during the early summer and the soybeans may be sown broadcast about July 1 and harrowed in. One bushel of seed to the acre will be required. One bushel of rye to the acre should be sown at the same time, for when the beans are killed down by the frost in the fall the rye will then serve as a cover-crop for the winter. When the soil is so hard and forbidding that clover will not thrive, the soybean may be made to serve as a nitrogen-gatherer. See *Glycine*.

L. A. CLINTON.

SPENDÓNCEA: *Cadia*. S. *tamarindifolia*, Desf.—*Cadia purpurea*. H.F. II. 4:114

SPANISH BAYONET: *Yucca*. S. Broom: *Spartium junceum*. S. Lime: *Melicocca bijuga*. S. Oyster Plant: *Scolymus*.

SPARAXIS (Greek word referring to the torn or lacerated spathes, a character which distinguishes this genus from *Tritonia*). *Iridaceae*. WAND-FLOWER. Bulbs or corms with fibrous coating, the plants suitable for outdoor planting but grown mostly under glass.

Stems simple or slightly branched: lvs. few, flat, sword-like or broadly linear, erect or falcate: spathes few, remote or sometimes solitary, broad-striate or frequently marked with short brown lines: fls. 1 to a spathe, sessile, rather large, yellow; perianth-tube short and slender, 6-lobed; ovary 3-celled: caps. membranaceous, ovoid or oblong, included in the spathe.—About 3 species, Cape Colony, S. Afr. *Sparaxis* is a group of spring-blooming Cape bulbs of the *Ixia* tribe, with spikes of 6-petaled, more or less funnel-shaped fls. 1-2 in. across and exhibiting an extraordinary range of color and throat-markings.

These plants are less popular than *ixias*, which they much resemble. The plants are dwarfer and more compact than *ixias*, usually 6-12 in. high, the spikes are shorter and fewer-fl'd., and the blossoms are sometimes larger. *Sparaxis* is essentially distinguished from *Ixia* and other allied genera by the subregular perianth, unilateral and arcuate stamens, and scarious lacerated spathe-valves.

Although a few plants of *sparaxis* are occasionally cultivated in America by bulb-fanciers, one may search through many American catalogues without finding them listed. The Dutch bulb-growers offer twenty-five distinct kinds, which is perhaps a quarter of the number of varieties of *ixias* in cultivation. According to J. G. Baker, there is "only one species in a broad sense, varying indefinitely in the size and coloring of the flowers." For practical purposes Baker recognizes the three species given below; of these the most important and variable is *S. tricolor*.

3654. *Sparaxis tricolor*.
($\times \frac{1}{2}$)

Sparaxis pulcherrima of the Dutch trade is properly *Dierama pulcherrima*, Baker. This grows as much as 6 feet high and has pendulous bright blood-purple flowers but apparently with pale rose and perhaps other varieties (also a white variety). It is distinguished by its pendulous flowers with regular perianth, simple style-branches, equilateral stamens, and large bracts which are not lacinate. B.M. 5555. F.S. 17:1810. Gn. 20:588; 44, p. 281. G. 16:386; 29:197. G.L. 27:152. This plant is said by F. W. Burbidge to be "perhaps the most graceful of all the Cape irids." (See Vol. II, page 1007.)

A. Throat of fl. same color as segms.

B. Fls. small; segms. $\frac{1}{2}$ – $\frac{3}{4}$ in. long.

bulbifera, Ker. Corm globose, $\frac{1}{2}$ – $\frac{3}{4}$ in. thick: basal lvs. about 4, linear or lanceolate, $\frac{1}{2}$ –1 ft. long: sts. $\frac{1}{2}$ –1 ft. long, simple or branched, bearing low down 2-3 small lvs., often with bulbils in the axils: fls. solitary or few in a spike, yellow; perianth-tube $\frac{1}{2}$ in. long. B.M. 545 (as *Ixia bulbifera*).—To this species Baker refers *S. albiflora*, Eckl., with fls. whitish inside, and *S. violacea*, Eckl., with dark purple fls.

BB. Fls. larger; segms. 1 in. or more long.

grandiflora, Ker. Habit, corm, lvs., and spathe just as in *S. bulbifera* but the fls. larger, the limb 1 in. or

more long, usually yellow or purple, and larger anthers. B.R. 258 (fls. white inside, midvein on the back purple). B.M. 541 (as *Ixia grandiflora*; fls. rich purple, margined lighter); 779 (fls. primrose inside, flamed purple outside).—The principal named forms are: Var. *atropurpurea*, Hort., dark purple; var. *anemonæflora*, Hort., pale yellow; var. *Liliago*, Baker, white, flushed with claret-purple outside; and var. *stellaris*, Baker, dark purple, the segms. narrower than the type, oblanceolate and acute rather than oblong.

AA. Throat of fl. bright yellow, often with a dark blotch on the lower part of each segm.

tricolor, Ker. Fig. 3654. Differs from *S. grandiflora* only in the color of the fls., which are very variable but always have a bright yellow throat and often a dark blotch at the base of each segm. B.M. 381 (as *Ixia tricolor*); 1482. F.S. 2:124. F. 1843:213 (as *S. picta*, *S. purpurea*, *S. pulchella*).—According to Baker, this is the favorite species among cultivators. It certainly has the greatest variety of colors and markings. In the works cited the floral segms. range from nearly white through rose, brick-red, carmine, crimson, and light purple to dark purple, excluding blue and yellow, which latter color usually appears in the throat.

WILHELM MILLER.

SPARGANIUM (Greek, *fillet*, referring to the ribbon-like leaves). *Sparganiaceae*. BUR-REED. Marsh or aquatic herbs which may be used in the bog-garden or along the pond-edge. Pflanzenreich, IV, 8. 1900.

Leaves alternate, sessile, linear-elongate, erect or floating, entire: fls. monœcious, in globular, sessile, or pedunculate heads, the upper bearing 3-androus, naked fls. and minute scales, the lower consisting of numerous sessile or shortly pedicelled pistillate fls.; ovary 1-2-celled: fr. obovoid or spindle-shaped, 1-2-seeded.—About 15 species, temperate and subfrigid regions of the northern hemisphere and in Austral. Bur-reeds are marsh herbs closely allied to cat-tails but with fls. in globular heads instead of oblong spikes. A few hardy perennial kinds are advertised by collectors of native plants and one or two are procurable from specialists in aquatics. Bur-reeds are desirable only in bog-gardens or in wild-gardening operations. The beauty of these plants often lies in each species being massed alone, as well as in the mixing with other plants.

A. Infl. unbranched.

simplex, Huds. Sts. weak and slender, $1\frac{1}{2}$ –2 ft. high, unbranched: lvs. more or less triquetrous: staminate heads 4-6; pistillate 2-6, 5-8 lines in diam.: fr. stalked. June-Aug. N. Amer.

AA. Infl. branched.

B. Height 3-8 ft.

eurycarpum, Engelm. Sts. stout, 3-8 ft. high, branching: lvs. linear, flat, slightly keeled beneath: staminate heads numerous, pistillate 2-4 on a st. or branch, 10-16 lines in diam.: fr. sessile, angled, depressed at the summit. May-Aug. N. Amer.

BB. Height 2-4 ft.

ramosum, Huds. Lvs. 3-angled at the base, long and linear: heads 5-9, disposed in axillary and terminal, interrupted spikes, the lowest one larger and pistillate, the others wholly staminate; pistillate heads 8-10 lines in diam. July. Old World.

WILHELM MILLER.

SPARMANNIA (named for Andreas Sparmann, 1747-1787). *Tiliaceae*. Shrubs or trees, with soft stellate pubescence, grown in the greenhouse and also out-of-doors in the southern United States.

Leaves cordate, dentate, or lobed: fls. white, in terminal, umbelliform little cymes; sepals 4, petals 4, naked at the base; stamens numerous, free; ovary nearly 4-celled: caps. globose, spiny.—About 5 species, Afr.

Sparmannia africana is of easy treatment under glass in a moderate temperature with plenty of air and light. The plants are benefited by being plunged in the garden in the summer and syringed during dry weather. Plants should be potted early in spring. The tips of young shoots root readily with 60° of heat.

A. Lvs. deeply 5-7-lobed.

palmata, E. Mey. A slender shrub much smaller in all its parts than *S. africana*: branches half-herbaceous: lvs. on long petioles, the lobes long-acuminate, incisely sinuate and unequally toothed, prominently 5-7-nerved below: fls. white or purplish, densely arranged on the subterminal peduncles: caps. 4-celled. S. Afr.—Springly cult. in S. Calif.

AA. Lvs. not lobed.

africana, Linn. A large shrub or tree, 10-20 ft. high: lvs. cordate-acuminate, 5-7-angled, unequally toothed, 5-6 in. long, 7-9-ribbed below: fls. white, on many-fld. peduncles: caps. 5-celled. S. Afr. B.M. 516. G.M. 37: 233. R.H. 1858, p. 105. Gn. 45:528; 76, p. 192. G. 22: 689; 27:195. Gn.W. 22: suppl. March 25. G.W. 5, p. 566.—A useful greenhouse plant. Var. *fiore-pleno*, Hort., is also grown. G.C. II. 19:477.—*S. africana* is not common in S. Calif., but is highly esteemed. One specimen, 40 years old, is 12 ft. high and 16 ft. through, and consists of about 50 trunks $\frac{1}{2}$ -4 in. diam. It is literally covered with snowballs of 4 in. diam., the blooms being so heavy that the ends of the branches touch the ground, necessitating severe pruning as soon as blooms were past beauty. No viburnum, hydrangea, or other shrub can compare with it at its blooming season. During the remainder of the year it has the appearance of a clump of basswood suckers, the lvs. being nearly identical in appearance with those of the basswood. It is therefore a dense mass of broad lvs. and looks well anywhere and at any time. This is one of the finest white-fld. shrubs or trees in cult. The double variety is not so desirable as the single. (Ernest Braunton.)

F. W. BARCLAY.

SPARTINA (Greek, *spartine*, a cord, referring to the tough leaves). *Gramineæ*. Perennial marsh-plants of various parts of the world, most or all of which are found in the U. S.: culms rigid and reed-like: lvs. coarse and rough, usually becoming rolled inward: spikelets 1-fld., strongly flattened, sessile, closely imbricated in 2 rows on one side of a narrow rachis; spikes 2 to several in a raceme.—Species about 10, most of them found in saline marshes of the seacoast.

Michauxiana, Hitchc. (*S. cynosuroides*, Amer. Auth., not Roth). FRESH-WATER CORD-GRASS. Fig. 3655. Culms 3-6 ft.: blades narrow, 2-4 ft., tapering to a long slender point, flat but soon involute in drying, the margins very scabrous: spikes 5-20, scattered, spreading, 2-4 in. long.—In the West known as "slough-grass." A common coarse fresh-water marsh grass, occurring across the continent in the northern states. Recommended for cult. along the margins of ponds and artificial lakes. Procurable from collectors.

S. cynosuroides, Roth (*S. polystachya*, Willd.), on the Atlantic and *S. foliosa*, Trin., on the Pacific coast act as mud-binders and are important factors in the natural reclamation of salt-marshes. In England, *S. stricta*, Roth, and *S. Townsendii*, Groves, perform the same service. G.C. III. 43:33. *S. alterniflora*, Loisel., is common to the British Isles and the St. Lawrence and New England coasts.—A yellow-margined form (*S. cynosuroides* var. *aureo-marginata*) is shown in G. 31:171.

A. S. HITCHCOCK.

SPARTIUM (Greek, *spartos*, the ancient name of the plant). Syn., *Spartianthus*. *Leguminosæ*. Ornamental hardy shrub grown chiefly for its bright yellow flowers.

Leaves alternate, simple, small: fls. in terminal, loose racemes; calyx split above, hence 1-lipped, with 5 minute teeth; keel incurved, acuminate: pod linear, compressed, many-seeded; seeds with callose appendage at the base, like in *Genista*.—One species in the

Medit. region and the Canary Isls. Allied to *Genista* and *Cytisus*, but chiefly distinguished by the 1-lipped calyx. The slender branches yield fiber, which is used in S. France and Spain for making ropes, cords, and cloths.

This is a handsome shrub with long and slender rush-like green branches, small and sparse foliage and showy papilionaceous flowers in terminal racemes. It is especially adapted for warmer and drier regions; in the East it is probably hardy as far north as Philadelphia. It becomes naturalized easily, as happened in several localities in South America, whence it was afterward described as *S. americanum*, Meyen. It grows in almost any kind of well-drained soil and is well suited for planting on exposed sandy and rocky situations. Propagation is by seeds and by greenwood cuttings under glass.

juncum, Linn. (*Genista juncea*, Lam. *Spartianthus junceus*, Link). SPANISH BROOM. Upright shrub, 10 ft. high, with slender, terete, green, rush-like branches sparingly leafy or almost leafless: lvs. oblanceolate to linear, entire, bluish green and sparingly appressed pubescent, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long: fls. fragrant, yellow, about 1 in. long, with ample standard: pod linear, pubescent, 2-3 in. long. June-Sept., in Calif. blooming almost the whole year. B.M. 85. B.R. 1974 (as *S. acutifolius*). Gn. 22, p. 404; 34, p. 284; 44, p. 57.—There is a double-fld. form. Var. *ochroleucum*, Sprenger, has whitish fls.

For other species sometimes referred to Spartium see *Genista* and *Cytisus*. For *S. aetense*, Biv., *S. ferox*, Poir., *S. monospermum*, Linn., *S. radiatum*, Linn., and *S. virgatum*, Ait., see *Genista*; for *S. purgans*, Linn., *S. scoparium*, Linn., and *S. multiflorum*, Ait., see *Cytisus*.

ALFRED REHDER.

SPARTOCYTISUS FILIPES, Webb.: *Cytisus filipes*.

SPATHELIA (from the Greek for a staff). *Ruidææ*. Odd evergreen trees without branches, grown in the warmhouse and the American tropics.

Trunk simple, the lvs. aggregated at its extremity, so that the plant has the look of a tree-fern or palm: lvs. alternate, odd-pinnate; lfts. many-paired, alternate, linear-oblong or sickle-shaped, subentire or serrate, the margin glandular: fls. polygamous, rather large, short-pedicelled, in large panicles, which are terminal, elongated and branched, the ultimate branches somewhat cymose; calyx 5-parted, the segms. spreading, valvate or subvalvate; petals 5, imbricate; disk none; stamens 5; ovary 3-angled, 3-celled: drupe without juice, elliptic-oblong, 3-edged, 3-winged, the shell stony.—About 5 species, W. Indies.

simplex, Linn. St. slender, usually leaning, resembling a palm, 20-50 ft. high: the lvs. and panicles are frequently several feet long; lfts. 20-40 pairs, very variable, opposite or alternate, sessile or petiolulate, cordate or obliquely rounded at base, oblong- or linear-lanceolate, crenate or entire: panicle powdery. Sometimes planted in the W. Indies. B.R. 670.

F. TRACY HUBBARD.

3655. *Spartina Michauxiana*.

SPATHIPHYLLUM (Greek word, referring to the leaf-like spathes). *Aracæ*. Stemless or short-stemmed herbs, used as warmhouse foliage plants.

Leaves large, oblong or lanceolate, acuminate or cuspidate, midrib strong: spathe lf.-like, membranaceous, oblong or lanceolate; spadix shorter than the spathe, sessile or stipitate, cylindrical, densely fld.: fls. hermaphrodite, all fertile; perianth-segms. 4, 6, or 8, connate or coherent in a truncate or lobed cup; stamens 4, 6, or 8; ovary oblong, 3-4-celled: berry globose or oblong-conical, 3-celled, cells 1-2-seeded.—About 27 species, mostly from Trop. Amer., one or two Malayan. Monographed by Engler and Krause in Engler's *Pflanzenreich*, hft. 37 (IV. 23B), 1908. Gardeners recommend as soil for their cult. a mixture of leaf-mold, peat, and fibrous loam, together with some sand and charcoal.

A. *Petals free, 6-8, in 2 rows, sometimes stuck together, never connate; stamens 6-8, rarely 4 or 5; ovary 3-4-celled, oblong, style pyramidal, more or less exserted, coronate.*

Section EUSPATHIPHYLLUM.

B. *Ovary-cells 8-, 6-, or 4-ovuled.*

cochlearispâthum, Engler (*S. heliconiifolium*, Schott). Caudex short: lvs. thin, membranaceous, broadly oblong, margin usually slightly undulate, base rotundate or subcordate, 20-30 x 8-10 in.: spathe oblong, 6-12 in. long, base more or less acute, apex gradually narrowed to a cusp, somewhat decurrent on the peduncle. Mex. I.H. 21:189.

BB. *Ovary-cells 2-ovuled.*

blândum, Schott. Lvs. elliptic-oblong or oblong, acute, base rather suddenly narrowed and concaved, 10 x 4 or more in.: spathe pale on both surfaces, elliptic-oblong, about 3 in. long, base suddenly narrowed, apex cuspidate-acuminate, narrowly decurrent on the peduncle. Dutch Guiana.

AA. *Petals free; ovary shortly obpyramidal, hexagonal, top truncate, style not at all distinct.*

Section AMOMOPHYLLUM.

B. *Petiole about equaling or slightly shorter than blade.*

floribûndum, N. E. Br. Lvs. oblong-elliptic or oblong-lanceolate, base obtuse finally abruptly contracted to a knee or acute, apex acute, about 6 x 3 in., upper surface rich green, lower paler: spathe white, oblong-lanceolate, about 3 in. long, long-cuspidate; spadix yellow-green or whitish. Colombia. I.H. 21:159 (as *Anthurium floribundum*). F. 1880, p. 76.

BB. *Petiole almost twice as long as blade.*

Patinii, N. E. Br. (*S. candidum*, N. E. Br.). Lvs. elongate-lanceolate, both ends long-narrowed, apex very acute, 8-9 x 1½-2½ in.: spathe whitish, oblong-lanceolate, about 2¾ x ¾ in. Colombia. I.H. 27:397. F.M. 1875:160. F. 1879, p. 19.

AAA. *Petals connate in a 6-angled cup which is truncate or 6-lobed; stamens 6; ovary obovoid or ovoid and 3-celled, top rather flat; cells 2-, 4-, 6-, or 8-ovuled.*

Section MASSOWIA.

cannæfolium, Schott; also spelled *cannifolium* (*Pòthos cannæfolia*, Dry. *S. candicans*, Poepp.). Lvs. membranaceous, ovate-oblong or elliptic-oblong, base rather gradually running down to a knee, apex short-acuminate, slightly unequally so, 12-32 x 4-6 in., upper surface dark green, shining, lower paler and dull: spathe stiffly membranaceous, outside green, inside white, lanceolate, or elliptic-oblong, 4½-8 in. long, base suddenly narrowed, scarcely decurrent, apex short-cuspidate; spadix greenish or yellowish. W. Indies. Colombia. B.M. 603.

Hybrid, unclassified.

hýbridum, N. E. Br. A hybrid between *S. cannæfolium* and *S. Patinii*. Petioles 6-8 in. long; lf.-blades broadly lanceolate to oblong-lanceolate, acuminate, 8-9 in. long: spathe white on both sides, lanceolate, acuminate, 4-5 in. long; spadix 2 in. long. I.H. 29:450. G.C. II. 19:500.

S. Ghiesbreghtii, Hort., is offered in the trade, but is unknown botanically.—*S. pictum*, Hort. Lind.=*Rhodospatha picta*.

F. TRACY HUBBARD.†

SPATHODEA (Greek, *spathe-like*, referring to the shape of the calyx). *Bignoniæacæ*. Two or 3 evergreen trees native of Trop. Afr. with large odd-pinnate opposite or sometimes ternate lvs., the lfts. entire, and with large fls. in terminal panicles or racemes: calyx large, split on one side and recurved, exposing the corolla to the base; corolla large, broadly campanulate and ventricose; stamens 4, exserted but shorter than the corolla, with spreading and pendulous anther-cells; disk large, cup-shaped; ovary oblong, with the ovules in several rows: caps. oblong-lanceolate, acuminate at the ends, loculicidal with woody valves; seeds elliptic, broadly winged.—The spathodeas are handsome evergreen trees with large pinnate foliage and large and very showy orange-red or scarlet fls. They can be grown only in sub-tropical or tropical countries and demand rich and well-drained soil with sufficient moisture during the growing period; they are rarely grown in greenhouses, as they need much space and do not bloom until they have attained a large size. Prop. is by seeds or by cuttings. See also *Radermachia* for cult.

campanulâta, Beauv. Tree, to 70 ft., glabrescent: lvs. 1-1½ ft. long; lfts. 9-19, short-stalked, ovate-lanceolate, abruptly short-acuminate, entire at the base with 2 or 3 fleshy glands, glabrous or somewhat pubescent beneath while young, 2-4 in. long: fls. scarlet, in many-fld. racemes or panicles; calyx coriaceous, boat-shaped, recurved, 2½ in. long; corolla about 4 in. long, with ovate, plicate, and somewhat undulate lobes; ovary papillose: caps. 8 in. long, glabrous. Trop. Afr. B.M. 5091. F.S. 8:830. J.F. 4:388. G.C. III. 50:458.

nilôtica, Seem. Shrubby tree, to 20 ft.: branchlets pubescent: lvs. ½-1½ ft. long; rachis pubescent; lfts. 9-15, ovate-oblong, short-acuminate, entire, glabrous above, densely pubescent or tomentose beneath, 1½-4 in. long: fls. almost like those of the preceding species, in short dense racemes; calyx densely tomentose, 1½-2 in. long. Cent. Trop. Afr. H. Johnston, Uganda protectorate, 1:68.—In its smaller size this tree has an advantage over the preceding species the fls. of which are usually borne so high on the tree as to be almost out of sight.

S. lævis, Beauv., is now referred to *Newbouldia* which differs from *Spathodea* chiefly in the shape of the calyx which incloses the base of the corolla and is split on one side and 2-lobed at the apex, and in its funnelform-campanulate corolla, the inclosed stamens with parallel anther-cells: caps. elongated-linear with leathery valves; seeds with the wing emarginate on one side. *N. lævis*, Seem. (*Spathodea speciosa*, Brongn.). Shrub or tree, to 40 ft., nearly glabrous: lvs. opposite or ternate, 1-2 ft. long; lfts. 7-13, ovate-oblong, obtusely acuminate, serrate, glabrous or nearly so, 3-8 in. long: fls. white with purple spots or pink or purple, in dense terminal panicles; calyx oblong, 2-lobed at the apex, ¾-1 in. long; corolla 2-2½ in. long, limb slightly 2-lipped with spatulate-obovate lobes. Trop. W. Afr. B.M. 4537. J.F. 1:51. F.S. 6:634. H.U. 5:357. The bark has medicinal properties.—*S. pentandra*, Hook. (B.M. 3681), is apparently a form of *N. lævis* with 6-lobed pale purple corolla and 5 stamens.—*S. speciosa*, Brongn.=*Newbouldia lævis*.

ALFRED REHDER.

SPATHOGLÓTTIS (Greek, *spathe* and *tongue*; said to refer to the shape of the lip). *Orchidæacæ*. Plants agreeing with *Bletia* in habit and form of inflorescence; terrestrial orchids of the Old-World tropics, mostly with numerous flowers.

Pseudobulbs broadly conic, 1-3-lvd.: lvs. elongate, long-petioled, narrow, plicate, articulated: scape lateral, bearing large fls. in a terminal raceme: sepals free, subequal; petals similar or broader and longer;

labellum not spurred, lateral lobes somewhat convolute, middle lobe clawed; column slender; pollinia 8.—About 40 species in Asia, Austral., and the Malay Isls.

Spathoglottises grow best at the warm end of the cattleya or Brazilian house in a moist shady location. Pot culture suits them best, and the compost should consist

principally of equal parts peat fiber and sphagnum moss with a little chopped sod added; about half of the pot should be devoted to drainage. They all require a liberal amount of water when growing, but only enough to keep them in sound condition when at rest. They are rather hard to increase by division and the supply depends upon new importations. (Robt. M. Grey.)

plicata, Blume. Lvs. 2-4 ft. long, finely acuminate; scape 2-3

ft. high, with a raceme 6-12 in. long; fls. 1 in. across, lilac; sepals and petals broad, acute; middle lobe of the labellum long and narrow, cuneately dilated at the tip; calli yellow, villous. Malay Penins. O. 191:48.

aurea, Lindl. (*S. plicata*, Griff.). Lvs. 12-18 in. high, narrowly lanceolate; scape tall and stout, 2 ft. high; raceme 6-8 in. long; fls. 1½ in. across, golden yellow; sepals broad, obtuse; middle lobe

of the labellum equaling the falcate lateral lobes, narrowly lanceolate. Malay Penins. G.C. III. 4:93.—The lip varies, being sometimes broad and retuse at the apex.

Viellardii, Reichb. f. (*S. Augustorum*, Reichb. f.). Fig. 3656. Lvs. long-lanceolate, acuminate, 1-2 ft. long; scape 12-18 in. high, robust; raceme 6 in. long, broad, corymb-like at first; fls. 2 in. across, very pale lilac, nearly white; sepals and petals ovate-oblong, subacute; labellum as long as the sepals, lateral lobes orange-brown, with orange calli speckled with red, middle lobe narrow, with a broadened tip variable in form. New Caledonia. B.M. 7013. A.G. 12:93. A.F. 6:631. J.H. III. 51:425.

S. aureo-Viellardii, Hort., is a hybrid between this and *S. aurea*. Fls. pale chrome-yellow, with the sepals slightly and the petals profusely dotted with crimson, the tips of the lobes of the lip rich crimson. G.C. III. 23:309. G.M. 41:308.—*S. Colmanii*=*S. aurea* var. x *S. aureo-Viellardii*.—*S. edwardsii*=*S. Fortunei* x *S. pulchra*.—*S. Hardingiana*, Par. & Reichb. f. Scape basal, up to 15 in. tall; fls. numerous, rose-purple or pale lilac, about 1 in. diam.; sepals lanceolate; petals linear-lanceolate; lip linear, auricled at base, with 2 yellow brown-spotted tubercles. N. Burma. B.M. 7964.—*S. kewensis*=*S. plicata* var. *Micholitzii* x *S. Viellardii*.—*S. Kimballiana*, Hook., is often regarded as a variety of *S. aurea*, from which it differs in having the backs of the sepals mottled with red-brown, the crest glabrous, and narrower lvs. B.M. 7443.—*S. plicata* var. *Micholitzii* is advertised by Sander. Fls. amethyst-color, with the segms. broader than in the type. Habit more dwarf.—*S. Southerniana*, F. M. Bailey. Fls. in upright spikes, more than 1 in. across; sepals and petals light rose-color. Queensland.—*S. zebrina*=*S. Fortunei* x *S. plicata*.

HEINRICH HASSELBRING.

SPATHYEMA: *Symplocarpus*.

SPATTER-DOCK: *Nuphar advena*.

SPEARMINT: *Mentha*. Spear-wood: *Eucalyptus doratoxyloides*. Spearwort: Species of *Ranunculus*.

SPECULÀRIA (from *Speculum Veneris*, meaning Venus' looking-glass). *Campanulaceæ*. VENUS' LOOKING-GLASS. Erect or decumbent, hispid or glabrous annual herbs, suitable for outdoor garden planting.

Leaves alternate, entire or dentate; fls. blue, violet, or white, sessile or short-pedicelled, axillary; calyx-tube adnate, oblong or linear, limb 5-parted; corolla subrotate, or broad-campanulate, 5-lobed; stamens free; ovary inferior, 3-celled: caps. oblong or linear.—About 10 species, northern hemisphere, 1 also occurs in S. Austral. Closely allied to *Campanula* but differing by the very long calyx-tube, ovary, and caps. The long calyx-tube is one of the most conspicuous features of the plant and has perhaps served to suggest the handle of the mirror. There is one North American species, *S. perfoliata*, which differs from all the rest in having perfoliate lvs. and the caps. dehiscing laterally near the middle instead of near the calyx-lobes. It is a weed.

S. Speculum is a pretty little hardy annual herb with five-lobed blue flowers not quite an inch across. The plants grow about 9 inches high, bloom in spring and summer and are desirable for edging flower-beds. They are of easy culture. See *Annuals*.

A. Peduncles about 3-fld.

Spéculum, DC. (*Campanula Spéculum*, Linn.). VENUS' LOOKING-GLASS. Fig. 3657. Erect, 9 in. high: calyx glabrous or pubescent, the tube constricted at the apex; lobes finally reflexed, according to DeCandolle. Eu. B.M. 102. Var. *alba*, Hort., is a white-fl. form. Gn. 72, p. 253. Var. *procumbens*, Hort., is offered abroad in addition to lilac and double forms. R.H. 1897, p. 254.

AA. Peduncles 1-fld.

pentagônia, DC. Calyx pilose, lobes spreading. Asia Minor. B.R. 56.—This species is not now advertised in Amer. Some specimens have narrow lvs. and longer calyx-tube than *S. Speculum*. An interesting feature of this species (and perhaps others) is the 5-angled fl-buds. F. TRACY HUBBARD.†

SPEEDWELL: *Veronica*.

SPELT: *Triticum*.

SPÉRGULA (Latin, *spargere*, to scatter; the seeds are said to be expelled). *Caryophyllaceæ*. Annual herbs including SPURRY (which see), a forage plant adapted to poor dry sandy soils: lvs. subulate, appearing whorled from the cluster of secondary lvs. at the axil; stipules small and scarious: fls. pedicelled, in cymose racemes; sepals 5; petals 5, entire; stamens 10, rarely 5; styles 5, alternate with the sepals; ovary 1-celled, many-seeded: caps. 5-valved, the valves opposite the sepals.—About 5, possibly more species, temperate regions of the world. Some of the species are dichotomously branched, but the following has clusters of branches originating at or near the base.

3657. Venus' looking-glass.—*Specularia Speculum*. (×¼)

arvensis, Linn. Annual, 6–18 in. high, branched at or near the base, bright green, little if at all viscid: lvs. linear, clustered at the nodes in 2 opposite sets of 6–8 together, appearing as if verticillate: fls. numerous, small, white, about $\frac{1}{4}$ in. across and borne in terminal panicles: seeds papillate. Eu. *S. sativa*, Boern., the cult. SPURRY is a dull green viscid plant, with margined not papillate seeds. Eu. F. TRACY HUBBARD.†

SPHÁCELE (old Greek name). *Labiatae*. A score or more of shrubs or subshrubs, in Calif., Hawaii, and S. Amer., one or more of which has been listed for ornament, but apparently little known in cult. Fls. whitish to red or blue, in the axils of small bracts and forming verticillate racemes or spikes which may be simple or branched; calyx campanulate, about 10-nerved, enlarging in fr.; corolla-limb 4-parted, scarcely labiate; stamens 4, didynamous or nearly equal; style 2-lobed: nutlets ovoid, smooth. *S. chamædryoides*, Briquet (*S. campanulata*, Benth.), from Chile, is mentioned abroad: 2–3 ft., shrubby: lvs. oblong-lanceolate, short-stalked, wrinkled: fls. pale blue, $\frac{1}{2}$ – $\frac{3}{4}$ in. long about 2 in a whorl. B.R. 1382. Coolhouse plant.

SPHÆRÁLCEA (Greek for *globe*, and *Alcea*, the generic name of the marsh mallow). *Malvaceæ*. **GLOBE MALLOW**. Shrubs, subshrubs, or herbs, adapted to the warmhouse or outdoors in the far South.

Leaves frequently angled or lobed: fls. short-pedicelled, solitary, or arranged in axillary fascicles or in terminal racemes or spikes, violet or flesh-colored, rarely long-peduncled or red; bracteoles 3, free or united at base; calyx 5-cleft; staminal column divided at the top into many filaments; ovary many-celled: fr. subglobose, of many compressed, 2-valved, dehiscing, 2–3-seeded carpels, united in a ring around a central torus, from which they slowly separate.—About 65 species, 4 or 5 of which are S. African, the remainder from the warmer regions of N. and S. Amer. Several species have been mentioned in horticultural literature and occur occasionally in cult. One species has been intro. into Calif. Closely allied to *Abutilon* but with 3 bractlets instead of none.

A. Lvs. 5–7-lobed.

B. Fls. in spikes.

acerifolia, Torr. & Gray. Fig. 3658. Perennial herb, 2–6 ft. high: lvs. 3–4 in. long, cordate, palmately 5-lobed (sometimes with 2 or more basal lobes), coarsely serrate: fls. rose-color, varying to white, 2 in. across, 15 or more in spicate clusters terminating the branches. Rocky Mts. B.M. 5404.

BB. Fls. in umbels.

umbellata, Don (*S. vitifolia*, Benth. & Hook. *Malva umbellata*, Cav.). Erect branched shrub, 3 ft. or more high, flocculose-tomentose: lvs. long-petiolate,

cordate, somewhat 7-lobed, peltate, nerved, flat, glabrate and green above, hoary and ribbed beneath; the lobes short, acute, margin crenate: peduncles axillary, usually 3-fld., rarely 2- or 5-fld.: calyx broad-campanulate, leathery, 5-lobed, the lobes semi-ovate; petals scarlet, white at base, obcordate; filaments forming a white column. Mex. B.R. 1608. L.B.C. 3:222. Var. *tricolor*, Hort., is said to have reddish purple fls. striped with white and rose.

AA. Lvs. 3-lobed.

B. Fls. scarlet or rose.

Munroana, Spach. Perennial herb, 1–2 ft. high: lvs. broad at base, obscurely 3-lobed, crenate, sometimes incised: fls. scarlet or rose, 1 in. across: panicles axillary and terminal, numerous. Dry plains, Brit. Col. to Idaho and south. B.M. 3537 and B.R. 1306 (both as *Malva Munroana*). A.G. 11:539. G. 35:451.—Advertised in 1890 as the “sunset plant.” The same plant is said to be offered in some catalogues as *Malva miniata*.

BB. Fls. brick-red.

cisplatina, St. Hil. (*S. miniata*, Spach. *Malva miniata*, Cav. *M. miniata*, Jacq.?). Tender branching subshrub, 2–4 ft. high, formerly considered desirable for conservatory decoration in Oct. and Nov., when it produces its brick-red fls.: lvs. 1–2 in. long, 3-lobed, coarsely and unequally crenate, midlobe longest: fls. 1– $\frac{1}{4}$ in. across, in axillary, few-fld. cymose racemes. La Plata. The above description is from B.M. 5938.—*Miniata* means cinnabar-red, the color of red lead. There seems to be no reason why *S. cisplatina* and *S. Munroana* should be confused. The lvs. of *S. Munroana* are obscurely 3-lobed, the lobes broad, blunt and short; the lvs. of *S. cisplatina* are deeply and sharply cut, acuminate and narrowed toward the base, the lobes narrow and acute, the midlobe over twice as long as the side lobes. The color of the fls. is very distinct and the clusters are branched in *S. Munroana* but not in *S. cisplatina*.

F. TRACY HUBBARD.†

SPHÆROCÒDON (Greek, *globe* and *bell*, probably referring to the shape of the corolla). *Asclepiadaceæ*. Perennial herbs with a woody or tuberous rootstock, suitable only for the warmhouse: sts. erect, not twining: lvs. opposite, short-petioled, elliptic or oblong: fls. moderate-sized, in pedunculate sublateral umbel-like cymes; calyx 5-parted; corolla campanulate or somewhat so, 5-lobed, the lobes overlapping and slightly twisted to the left in bud; crown of 5 small fleshy compressed tubercles or teeth; column arising from the base of the corolla; anthers without appendages: fr. unknown.—Five species from Trop. and S. Afr. *S. obtusifolium*, Benth. Rootstock woody: sts. several to a root, erect, 1–3 ft. high, branching only at the base: lvs. elliptic, usually very obtuse and apiculate, sometimes subacute: fls. in sublateral, 6–13-fld. umbel-like cymes, dark purple; sepals linear-lanceolate, acute; corolla broadly campanulate, 5-lobed to one-third of the way down or more. Trop. and S. Afr. B.M. 7925.

SPHÆRÓGYNE: *Tococa*.

SPHEROSTÉMA: *Schizandra*.

SPHAGNUM. Sphagnum moss, bog-moss, or peat-moss is found in swamps or bogs and is one of the plants from which peat is formed; it is much used by gardeners. Its geographical distribution extends to all countries in the North Temperate zone. According to Warnstorff, 1911 (Engler's “Das Pflanzenreich”), there are 342 recognized species of Sphagnum, of which many occur in North America. Sphagnum mosses differ from the true mosses so much that they are usually classified in a distinct family, Sphagnaceæ. Besides differences in structure of the reproductive organs, the marked differences lie in the

3658. *Sphaeralcea acerifolia*. ($\times \frac{1}{4}$)

CVL Spinach.—Above, a plant of Long Season variety. Below, spinach field near Norfolk, Virginia.

larger growth of sphagnum (which is often a foot or more in height), its soft appearance, pale green color, and the absence of root-hairs. The stems and leaves are inclosed or encircled by one, two, and often four strata of transparent cells connected with each other by small holes, which have the capacity of sucking up and retaining a large amount of water. These cells therefore perform the function of root-hairs, and it is this abundant water-storage tissue that makes sphagnum moss of so much use to gardeners in the cultivation of orchids, anthuriums, and the like, and in fact most plants of an epiphytal or swamp-loving character, such as *sarracenia* and *darlingtonia*. Sphagnum often forms at least one-third of the compost in which pitcher-plants and epiphytes are grown. The fresh green tips of sphagnum are also most useful for surfacing pots of orchids and other plants. Besides giving them a better appearance, the moss acts as an index to the moisture condition of the plant. Sphagnum is also useful in the propagation of many stove plants, such as *cordyline*, *nepenthes*, and the like; for starting tropical tuberous-rooted plants, such as fancy *caladiums*; for sowing seeds of orchids, anthuriums, *nepenthes*, and *sarracenias* when fresh and chopped fine; as a mulch; as a non-conducting material for plants in pots in exposed positions in summer; and in packing plants for transportation, for which purpose it is an ideal material. Owing to its sponge-like character it may be used wet or dry, according to the character of the plants intended for packing.

Unless one has an ideal position in which to keep sphagnum moss after gathering it from its native place, or unless one has conditions very similar to its native habitat, it is difficult to keep it living for any length of time. This does not greatly matter, except that sphagnum used for surfacing pots should always be living for the sake of appearance. That which is used in potting and propagating need not necessarily be living as long as it is fresh and not decayed, while partially decayed moss may be used for mulching and packing.

EDWARD J. CANNING.

SPHEDAMNOCÁRPUS

(derivation unknown). *Malpighiaceæ*. Scandent or erect shrubs or subshrubs: lvs. opposite, entire, petiolate, without stipules, the petiole glandular: fls. rather large, in 3-4-fld. umbels, collected in terminal panicles; calyx 5-parted, not glandular; petals unequal, short-clawed, the lobes dentate or nearly entire; stamens 10; ovary 3-celled: samaras 3, with a vertical dorsal wing.—About 5 species, Trop. and S. Afr. *S. pruriens*, Szyszyłowicz (*Acridocarpus pruriens*, Juss.). A tall climbing shrub, silky-tomentose on most of its parts: lvs. opposite, ovate-oblong, 1-4 in. long: fls. subcorymbosely clustered at the ends of the branches, 1-1½ in. diam., golden yellow; petals short-clawed, orbicular, margins crisped: samaras silky-pubescent. S. Afr. B.M. 7894.

SPHENÓPHOLIS (Greek, *sphen*, a wedge, and *pholis*, a scale, referring to the broadly obovate second glume). Syn., *Eatonia*, Endl., not Raf. *Gramineæ*. Slender perennials with rather delicate panicles: spikelets 2-3-fld., articulated below the glumes; glumes dissimilar in shape, the first narrow, the second obovate.—Species about 5, N. Amer. Three kinds have been catalogued among native plants offered for sale.

A. *Panicle dense, spike-like, strict.*

obtusata, Scribn. Spikelets crowded on the short, erect panicle-branches; upper glume rounded-obovate, very obtuse. Dry soil throughout U. S. Dept. Agric., Div. Agrost. 7:258.

AA. *Panicle more loose and slender.*

pállens, Scribn. (*Eatonia pennsylvanica*, Gray). Lvs. 3-6 in. long: panicle-branches lax, nodding, glumes unequal, the first shorter. Moist woods and meadows. Maine to Texas. Ibid. 257.

nftida, Scribn. (*Eatonia Dudleyi*, Vasey). Lvs. 1-2 in. long: panicle-branches spreading in flowering, afterward erect; glumes equal in length. E. U. S. Ibid. 259.

A. S. HITCHCOCK.

SPICE BUSH: *Benzoïn*.

SPIDER FLOWER: *Cleome*. S. Lilies: *Hymenocallis* and *Pan-cratiûm*. S. Plant: *Cleome*. Spiderwort: *Tradescantia*.

SPIGËLIA (named for Adrian von der Spigel, physician, 1558-1625). *Loganiaceæ*. Annual or perennial herbs, some hardy, the others either warmhouse or greenhouse plants, rarely somewhat woody, with opposite membranous feather-veined rarely 3-5-nerved lvs., and long or small, red, yellow, or purplish fls. usually borne in terminal one-sided somewhat curved spikes: calyx 5-lobed; segms. narrow; corolla tubular; lobes 5, valvate; stamens 5, attached to the corolla-tube; ovary 2-loculed; style articulated, simple, obtuse or somewhat capitate and stigmatose at the summit: caps. flattened, circumscissile above the persistent base.—About 50 species, Amer.

marilândica, Linn. **PINK-ROOT**. A handsome hardy perennial herb, with slender, tufted sts. 1-2 ft. high, opposite, ovate, sessile, thin lvs. 2-4 in. long, and red, tubular fls. with yellow throats in terminal, 1-sided spikes. June, July. Woods, N. J. to Wis. and south. B.B. 2:605. B.M. 80.—An elegant plant for the hardy border. Shade is not necessary for its welfare if planted in good loose deep loam.

S. splendens, Hort., grows 1½ ft. high: lvs. 4-5 in. long, contracted to a short petiole, obovate-oblong: fls. bright scarlet, 1 in. or more long, in revolved spikes. July. Mex. and Guatemala. B.M. 5268. G.W. 2, p. 417; 7, p. 362.

F. W. BARCLAY.

SPILÁNTHES (Greek, meaning *spot-flower*, in reference to the markings on the disk in some of the species). *Compositæ*. Herbs, mainly weeds, some of them desirable for outdoor planting, with opposite lvs.: rays yellow or whitish, or none: achenes nearly always flattened, biaristate or without bristles, glabrous or strongly ciliate, in the latter case quite distinct in appearance. There are about 40 species of *Spilanthes*, widely distributed in both hemispheres, mostly confined to warmer countries, or, in the New World, also occurring in the South Temperate zone; one variety native to Amer. Good technical characters for distinguishing the different forms are found in but few cases. The latest monograph is in the Proceedings of the American Academy of Arts and Sciences, vol. 42, pp. 521-69. *S. oleracea*, Linn. (Tropics), is cult. for the pungent flavor of its lvs., used in salads; also, to a slight extent, as an ornamental, on account of its odd cylinder-like heads, in which the ratio of length to breadth is the greatest in the genus. Two types of it are named in the trade, *Parâ cress* and *Brazil cress*, the latter said more commonly to have a brownish cast to sts. and lvs. Gn. 22, p. 295. Gt. 2, p. 36. While most of the species are of inferior appearance, several are distinctly worth cultivating or possibly hybridizing for ornament. The principal ones are enumerated below; all but *S. callimorpha* belonging in the radiate section, *Acmella*, DC.

S. americana, Hieron., var. *repens*, A. H. Moore. One of the best of the showy members of the genus. Erect or weak, ascending, decumbent, or rarely prostrate: lvs. large for the genus: rays bright yellow. By selection the erect type could probably be made to predominate. A hybrid combining with this the handsome lvs. and red st. of *S. phaneractis* would be most pleasing, were it producible. Sept. Mo., Ark., La. to Fla. and Texas.—*S. callimorpha*, A. H. Moore. Decumbent or prostrate: lvs. long-acuminate; internodes long: rayless species, but of pleasing appearance. Yunnan Province, China.—*S. charitopsis*, A. H. Moore. One of the dainty species; a fair companion-piece to *S. iodesca*, but with pale disks. Brazil.—*S. filipes*, Greenm. Erect plant with long internodes: small attractive heads. Yucatan, Mex.—*S. grisea*, A. H. Moore. Lvs. densely hispidulous: rays large, very bright yellow. Paraguay.—*S. iodesca*, A. H. Moore. A dainty little plant, with delicate green foliage; disk violet, the tiny rays creamy. Porto Rico. Though not quite so charming, *S. charitopsis* would be a pretty good companion.—*S. phaneractis*, A. H. Moore. Decumbent or

prostrate; sts. red; lvs. linear to linear-lanceolate; rays large, bright yellow. Known from states of Jalisco and Michoacan, Mex. One of the few very conspicuous-fl. species.—*S. poliolepidica*, A. H. Moore. Erect; rays golden yellow; plants hairy. Costa Rica.

ALBERT HANFORD MOORE.

SPINACH (*Spinacia oleracea*, which see) is an annual crop grown as a pot-herb, or for "greens." Fig. 3659. It is a cool-season plant, and therefore it is grown in fall to spring. It is a plant of easy culture, thriving in any good garden or field soil, although for quick results and for tender succulent foliage, land that has an abundance of available plant-food, and particularly of nitrogen, is most desirable. The plant is hardy, and when the land is well drained, it will ordinarily stand the winter climate as far north as the city of New York, and still farther in somewhat protected places.

Spinach is grown both as a fall and spring crop. The fall crop is raised from seed that is sown in August; in eight weeks the leaves may be large enough for eating.

3659. Spinach.

The spring crop is grown from seeds sown in autumn, or from those sown in winter in hotbeds or cold-frames, or from those sown directly in the open ground as soon as it is fit in the spring. If the plants for spring use are to be started in the fall, the seeds should be sown about six to eight weeks before hard freezing weather is expected. Then the plants will have attained sufficient size and roothold to enable them to pass the winter. It is advisable to cover the plants, just before winter sets in, with straw or loose litter or dry manure. Even though the plants will withstand the winter, they nevertheless thrive better if given this protection, particularly in soils that are likely to heave. It is customary to grow this fall-sown spinach on wide ridges or beds that are made by plowing several furrows together, leaving a dead-furrow between them. This allows of surface drainage. These beds may be from 5 to 10 feet wide. On these beds, the seeds are sown in rows running lengthwise, the distance between the rows being from 10 to 20 inches, depending on the methods that are employed for tillage. If hand tillage alone is to be given, the plants may be placed closer. In the spring the cover is removed from the plants at the earliest opportunity, for spinach is most desired very early in the season. Unless the land is in extra good "heart," it is well to make a surface application of a soluble fertilizer early in the spring in order to start the plants into growth. A fertilizer that is very rich in nitrogen gives best results; in fact, it is customary in some places to use a solution of nitrate of soda or sulfate of ammonia, applying the material with a sprinkling-cart. From fifty to seventy-five pounds of the fertilizer may be used to the acre with very good results at each of two or more applications.

For home use, spinach is sometimes carried over the winter in frames, the plants having been transplanted to the frames or raised in them during the late fall. These frames are protected from severe freezing weather by mats or shutters. Whenever it is desired to bring the plants into growth, sash is placed over the frame, and extra protection is given in very cold

weather. The plants will soon become green and begin to make new leaves. Different frames may be covered at different times as the season advances, thereby providing a supply for home use. Sometimes the seed is sown in hotbeds that are made late in winter or very early in spring, and the plants are secured in advance of the ordinary season. The growing of spinach in frames is less frequent than formerly, owing to the fact that the market is now supplied with the product grown in the middle South.

Spring spinach may be grown from seeds that are sown as soon as the land can be worked in spring. If the land has been plowed and manured in the fall, quicker results may be secured. Two or three sowings may be made in the home-garden for spring use, but after the middle of June spinach is likely to become tough and is in little demand. If spinach is wanted during the summer, it is better to use the New Zealand spinach, which is a warm-weather plant. This plant has no relationship with the ordinary spinach (see *Tetragonia*). It is usually best to sow spinach seed where the plants are to stand, although it is sometimes transplanted into frames for home use. Care must be taken that the plants do not become checked or stunted, else they will tend to run to seed. If the seed is sown too late in spring, when hot weather is approaching, the root-leaves will be very few and the plant will quickly throw up flower-stalks. Spinach is always grown as a succession or companion crop, as it occupies the land for a small part of the year. There are very few insects and diseases that are generally troublesome.

Spinach is usually transported to market in barrels or crates. Plants are usually cut so that an inch or so of the root is left with them. All dirt is removed, as also all broken and dead leaves. The plants are packed tight. It is essential that the plants be dry before they are shipped.

There are several important varieties of spinach. The large broad-leaved varieties are most popular in the markets, such as the Viroflay and the Round-leaved. The prickly spinach is considered to be the most hardy and is chiefly recommended for fall sowing. L. H. B.

SPINACIA (from *spina*; alluding to the spiny fruit). *Chenopodiaceæ*. **SPINACH**. **SPINAGE**. According to Volkens (in Engler & Prantl's "Pflanzenfamilien"), there are only two species of *Spinacia*, *S. oleracea*, Linn., the common spinach, and *S. tetrandra*, Stev., although Bentham & Hooker had made the genus to include four species. *S. tetrandra* is an annual herb of the Asia Minor-Persian region, and is not in cultivation. *S. oleracea*, the spinach, is probably native to southwestern Asia, and it is now widely cultivated. It is an annual herb, developing rather large arrow-shaped root-leaves, and these leaves are eaten for "greens." Later in the season it sends up a branching flower-stem 2 to 3 feet high, bearing axillary clusters of seed-like fruits. In one type these fruits are spiny: this is the form once described as *S. spinosa*, Moench, but which is not now considered to be specifically distinct. Whether the round-seeded or the prickly-seeded type is the original form of the spinach is not known, but as a matter of nomenclature, Linnæus' *S. oleracea*, which is the oldest name, is held to include all.

Spinacia belongs to the *Atriplex* tribe. The genus is distinguished from *Atriplex* in the fact that the pistillate flowers are bractless, whereas those of *Atriplex* are inclosed in a pair of enlarging calyx-like bracts. *Spinacia* is dioecious, bearing the flowers in small axillary clusters; stamens 4 or 5, in a 4- to 5-lobed calyx; ovary 1, with 4 to 5 styles or stigmas, in a 2- to 4-toothed calyx, this calyx hardening and inclosing the achene and often becoming horned on the sides and giving rise to "prickly-seeded" spinach. The cultivated forms have developed much thicker and broader radical leaves, which are used for greens, often showing little of the halberd or sagittate shape. See *Spinach*.

L. H. B.

SPIRÆA (ancient Greek name of a plant used for garlands, derived from *speira*, band, wreath; probably first used for the present genus by Clusius). *Rosaceæ*, subfam. *Spirææ*. SPIRÆA. Ornamental woody plants grown for their profuse handsome white, pink, or carmine flowers.

Deciduous shrubs: lvs. simple, short-petioled, dentate or serrate, sometimes lobed, rarely entire, without stipules; fls. in umbel-like racemes, corymbs or panicles, perfect, mostly polygamous; calyx cup-shaped or campanulate, 5-lobed; petals 5, rounded; stamens 15-60, inserted between calyx and disk; pistils usually 5, distinct, developing into follicles dehiscent along the inner suture, with several minute oblong seeds.—About 70 species in the temperate regions of the northern hemisphere, in Amer. south to Mex., in Asia south to the Himalayas. Many species formerly included under *Spiræa* are now referred to other genera; see *Physocarpus*, *Holodiscus*, *Sorbaria*, also *Chamæbataria*, *Luetkea*, *Petrophytum*, and *Sibiræa* for shrubby species, and *Aruncus*, *Filipendula*, and also *Astilbe* for the herbaceous ones. There is a monograph of *Spiræa* and the allied genera by Maximowicz in *Acta Horti Petropolitani*, vol. 6, pp. 105-261 (1879) and a monograph of the cult. species, with their numerous hybrids fully described by H. Zabel, *Die strauchigen Spiræen der deutschen Gärten* (1893). There is much horticultural literature on spireas, for the plants are popular and about two-thirds of the known species and numerous hybrids mostly originated in gardens are in cult.

The spireas are very ornamental, usually low or medium-sized shrubs with rather small deciduous foliage and with small white or pink or sometimes nearly crimson flowers in showy corymbs or panicles followed by small inconspicuous capsule-like fruits. Many are hardy North; some of the best of them are *S. arguta*, *S. Thunbergii*, *S. Vanhouttei*, *S. pubescens*, *S. trilobata*, *S. nipponica*, *S. media*, *S. ulmifolia*, *S. alba*, *S. Douglasii*, *S. Menziesii*, *S. tomentosa*. The recently introduced *S. Henryi*, *S. Veitchii*, *S. Wilsonii*, *S. Rostkornii* and *S. Sargentiana* have proved hardy at the Arnold Arboretum, while *S. blanda*, *S. japonica*, and *S. albiflora* require a sheltered position or protection during the winter, though *S. japonica* and its allies, even if killed almost to the ground, will produce flowers on shoots of the same season. *S. cantoniensis*, *S. Blumei*, *S. chinensis*, *S. canescens*, and *S. bella* are more tender and not to be recommended for the North, but are hardy or nearly hardy in the middle states. *S. prunifolia* is hardy as far north as Boston.

In regard to the flowering season, the spireas can be divided into two groups. The first one contains the species of the section *Chamædryon*, with white flowers in umbels and blooming in spring, from April to June. The second group is composed of the sections *Calospira* and *Spiraria*, with white or pink flowers in corymbs or panicles appearing from June to autumn. Some of the most important species, arranged according to their relative flowering-time, are the following: Early-flowering spireas—*S. Thunbergii*, *S. arguta*, *S. hypericifolia*, *S. prunifolia*, *S. media*, *S. pikowiensis*, *S. pubescens*, *S. chamædryfolia*, *S. trilobata*, *S. Vanhouttei*, *S. cantoniensis*, *S. nipponica*. Late-flowering spireas—*S. bella*, *S. Rostkornii*, *S. Wilsonii*, *S. Henryi*, *S. Sargentiana*, *S. Veitchii*, *S. corymbosa*, *S. densiflora*, *S. canescens*, *S. japonica*, *S. albiflora*, *S. salicifolia*, *S. alba*, *S. Menziesii*, *S. Douglasii*, *S. tomentosa*. Many species of the second group do not produce their flowers all at once like those of the first group, but continue blooming for a longer time.

The spireas are all medium-sized or low shrubs and well adapted for borders of shrubberies, as single specimens on the lawn, or for rockeries. Especially the species of the early-flowering group possess a graceful habit and make effective single specimens, except perhaps *S. chamædryfolia* and *S. media*, which are some-

what stiffer and less handsome and produce suckers. *S. canescens*, *S. Henryi*, and its allies have the graceful habit of the first group. *S. japonica* and its numerous hybrids form mostly low, round bushes and are pretty as single specimens or in the border. *S. alba*, *S. Douglasii*, *S. Menziesii*, and their hybrids should be planted in shrubberies only and especially in situations where their spreading by suckers does no harm; they are sometimes used for low ornamental hedges. For rockeries *S. decumbens*, *S. betulifolia*, *S. corymbosa*, *S. densiflora*, *S. bullata*, and some dwarf hybrids of *S. japonica* are to be recommended.

The species of the section *Chamædryon*, and also *S. canescens* and *S. bella*, should be pruned as little as possible—only thinned out and the weak wood removed—while those of the sections *Spiraria* and *Calospira* can be pruned more severely if necessary, since they produce their flowers at the ends of the young shoots. Some

3660. *Spiræa Thunbergii*.
($\times \frac{1}{2}$)

of the early-flowering spireas, especially *S. arguta*, *S. prunifolia*, *S. Vanhouttei*, and *S. Bumalda*, are sometimes forced.

The spireas grow in almost any moderately moist soil and do not stand drought well, the spiraria species being generally more moisture-loving; *S. tomentosa* thrives well only in a peaty or sandy soil, while those recommended above for rockeries require a well-drained soil and sunny situation. Propagation is by seeds sown in spring and covered only slightly with soil, or by hardwood or greenwood cuttings. The species of *Chamædryon* grow very well from greenwood cuttings under glass, while the spirarias are usually raised from hardwood cuttings. The calospiras seem to grow equally well in both ways. The spirarias are also often propagated by division and by suckers.

KEY TO THE SECTIONS.

- A. Infl. a simple umbel-like raceme: fls. white.
 Section I. CHAMÉDRYON. Species Nos. 1-20.
 AA. Infl. compound: fls. white or pink.
 B. Fls. in corymbs.
 Section II. CALOSPIRA. Species Nos. 21-42.
 BB. Fls. in panicles.
 Section III. SPIRARIA. Species Nos. 43-55.
- Section I. CHAMÉDRYON. Species Nos. 1-20.
- A. Fls. in sessile umbels with none or very small lvs. at the base or only the lower umbels on leafy stalks.
 B. Foliage entire or crenately dentate only near the apex, often 3-nerved, grayish green. 1. hypericifolia
 BB. Foliage dentate or serrate, usually penninerved, bright green.
 C. Shape of lvs. linear-lanceolate: glabrous. 2. Thunbergii
 CC. Shape of lvs. ovate to oblong-lanceolate: finely pubescent when young.
 D. Umbels on the lower part of the branches stalked.
 E. Lvs. oblong. 3. arguta
 EE. Lvs. obovate. 4. multiflora
 DD. Umbels all sessile, 3-6-fld. 5. prunifolia
 AA. Fls. in umbel-like racemes on leafy stalks.
 B. Margin of lvs. entire or crenate or dentate only toward the apex.
 C. Foliage grayish pubescent on both sides. 6. cana
 CC. Foliage almost glabrous.
 D. Shape of lvs. elliptic to oblong-lanceolate.
 E. Lvs. penninerved: shoots angular. 7. alpina
 EE. Lvs. all or partly 3-nerved.
 F. Shoots striped: lvs. all 3-nerved. 8. crenata
 FF. Shoots terete: lvs. partly penninerved, partly 3-nerved. 9. pikowiensis
 DD. Shape of lvs. almost orbicular, $\frac{1}{2}$ -1 in. broad. 10. nipponica
 BB. Margin of lvs. incisely serrate and often slightly lobed (only in No. 18 sometimes entire).
 C. Stamens shorter than or as long as petals; sepals erect or spreading in fr.
 D. Foliage glabrous.
 E. Form of lvs. orbicular to ovate.
 F. Apex of lvs. obtuse.
 G. Lvs. penninerved, ovate. 11. Blumei
 GG. Lvs. palmately 3-5-nerved, orbicular. 12. trilobata
 FF. Apex of lvs. acute. 13. Vanhouttei
 EE. Form of lvs. rhombic-lanceolate. 14. cantoniensis

DD. Foliage pubescent, at least beneath.

- E. Umbels and follicles pubescent.
 F. Tomentum grayish. 15. blanda
 FF. Tomentum yellowish. 16. chinensis
 EE. Umbels and follicles glabrous. 17. pubescens
 CC. Stamens longer than petals; sepals reflexed.
 D. Shoots terete, often pubescent. . . 18. media
 DD. Shoots angular, glabrous.
 E. Lvs. doubly and irregularly serrate from below the middle. 19. chamædry-
 EE. Lvs. simply serrate, usually only above the middle. 20. flexuosa

1. *hypericifolia*, Linn. Vigorous shrub, 5 ft. high, with slender arching or upright branches: lvs. almost sessile, cuneate-obovate to obovate-lanceolate, 3-nerved or with few lateral veins, almost glabrous, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. small, white, in sessile umbels; pedicels usually pubescent; petals almost orbicular, usually longer than stamens. April, May. S. E. Eu. to Siberia. —Variable species. Var. *acuta*, Ser. (*S. acutifolia*, Willd.). Lvs. narrower, oblanceolate: fls. smaller, yellowish white; pedicels glabrous; petals obovate, shorter than stamens: fls. somewhat earlier, but less showy. G.O.H. 9. Var. *flabellata*, Zabel (*S. flabellata*, Bertol. *S. hypericifolia* var. *crenata*, Boiss. & Buhse). Lvs. obovate to obovate-lanceolate, acute, incisely serrate at the apex or entire on the flowering branches. Var. *obovata*, Maxim. (*S. obovata*, Waldst. & Kit.). Lvs. obovate, rounded at the apex, crenate above the middle. S. E. Eu. G.O.H. 11. Var. *truncata*, Zabel (*S. thalicroides*, Hort., not Pall.). Lvs. broadly obovate to oblong-obovate, truncate and crenately dentate at the apex. Siberia.

2. *Thunbergii*, Sieb. Fig. 3660. Shrub, 5 ft. high, with spreading or arching branches: lvs. linear-lanceolate, sharply serrulate, 1-1 $\frac{3}{4}$ in. long: fls. pure white, about $\frac{1}{2}$ in. across, in 3-5-fld. naked umbels; petals

obovate, much longer than stamens: follicles with the spreading styles below the apex. April, May. China, Japan. S.Z. 1:69. G.F. 8:84, 85. J.H. III. 47:337. — A very graceful early-flowering shrub, the slender arching branches clothed with feathery bright green foliage, turning late in fall to orange or scarlet. Almost hardy, but tips of branches sometimes killed by severe frost; valuable for seaside planting.

3. *arguta*, Zabel (*S. Thunbergii* $\times$ *S. multiflora*). Similar in habit to the former but higher and more vigorous: lvs. oblong-obovate to oblong-oblanceolate, sharply and sometimes doubly serrate, glabrous at length, 1-1 $\frac{3}{4}$ in. long: fls. pure white, $\frac{1}{2}$ in. across, in many-fld. umbels, mostly with small lvs. at the base; pedicels glabrous; petals broadly obovate, almost twice as long as stamens. May. Of garden origin. G.C. III. 22:3; 43:398. Gn. 73, p. 578; 78, p. 82. A.G. 22:633. G.M. 44:385.

A.F. 17:192. Gn.W. 24:470. G.L. 27:33. Gng. 7:291. F.E. 11:160. G.F. 10:443. M.D.G. 1900:16.—The most free-flowering and showy of the earlier spireas; quite hardy.

4. *multiflora*, Zabel (*S. crenata* × *S. hypericifolia*). Shrub, 5 ft. high, with slender, arching branches: lvs. obovate, cuneate, serrate above the middle, usually 3-nerved, glabrous at length, about 1 in. long: fls. pure white, in many-fl. umbels, sessile on the upper, borne on leafy stalks on the lower part of the branches. May. Of garden origin.—Handsomely shrub similar to the former, but blooming a little later.

5. *prunifolia*, Sieb. & Zucc. Graceful shrub, 6 ft. high, with upright slender pubescent branches: lvs. ovate to oblong, denticulate, pubescent beneath, 1–2 in. long: fls. pure white, about $\frac{1}{2}$ in. across, on slender pedicels, in 3–6-fl. umbels; petals obovate, longer than stamens. May. China, Japan. J.C.T. 22:12. Var. *plena*, Schneid. (var. *flore-pleno*, Hort.). Fig. 3661. Fls. double, rather large. S.Z. 1:70. F.S. 2:153. Gn. 53, p. 185. A.G. 18:425. F.E. 9:593. Mn. 3, p. 42. G. 21:314; 27:132. G.M. 50:187. Gn.M. 3:208. F.E. 31:602.—Very handsome, early-flowering shrub, with dark green, shining foliage, turning orange in fall. The single-fl. form is less showy and rare in cult.; its foliage is lighter and not shining.

6. *cana*, Waldst. & Kit. Dense, bushy shrub, 3 ft. high: lvs. elliptic to oblong, acute at both ends, usually entire, grayish pubescent on both sides, more densely beneath, $\frac{1}{4}$ –1 in. long: fls. $\frac{1}{4}$ in. across, in dense head-like umbels; petals about as long as stamens; sepals reflexed in fr. May. S. E. Eu., W. Asia. R.F.G. 24:148.—Hardy, but not very showy.

7. *alpina*, Pall. Shrub, 4 ft. high, with upright or arching, angular, reddish brown branches: lvs. oblong-ovate to oblanceolate, acute, usually entire, glabrous, pinninerved, $\frac{1}{4}$ –1 in. long: fls. white, rather small, in short-stalked, small, glabrous umbels; petals roundish, little shorter than stamens; sepals upright in fr.: follicles curving outward. May, June. N. E. Asia. G.O.H. 8.—Hardy shrub, with graceful foliage.

8. *crenata*, Linn. (*S. crenifolia*, C. A. Mey.). Shrub, 3 ft. high, with slender striped branches: lvs. oblong-ovate to oblanceolate, acute at both ends, crenately serrate toward the apex, grayish green, puberulous beneath when young, 3-nerved, $\frac{1}{2}$ – $1\frac{1}{4}$ in. long: fls. white, rather small, in dense almost semi-globose umbels; petals roundish obovate, shorter than stamens; sepals upright in fr.: follicles with erect styles. May. S. E. Eu. to Caucasus and Altai. L.B.C. 13:1252. G.O.H. 10. R.F.G. 24:147.—Hardy.

9. *pikowiensis*, Bess. (*S. crenata* × *S. media*. *S. Nicoudierii*, Hort.). Shrub, 4 ft. high, with terete upright branches: lvs. oblong, cuneate at base, with few sharp teeth at the apex or sometimes entire, pinninerved to 3-nerved, almost glabrous, 1–2 in. long: fls. white or greenish white, in many-fl. almost glabrous umbels; petals orbicular, shorter than stamens; sepals upright in fr.: follicles with the upright style somewhat below the apex. May.—Supposed natural hybrid, found wild in Podolia, Poland.

10. *nipponica*, Maxim. (*S. bracteata*, Zabel, not Raf.). Fig. 3662. Shrub, 8 ft. high, with upright or spreading branches, quite glabrous: lvs. obovate, usually crenate at the apex, dark green above, bluish green beneath, of firm texture, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: fls. $\frac{1}{2}$ in. across, in umbel-like racemes, sometimes compound at the base; petals orbicular, longer than stamens; sepals spreading in fr. June. Japan. Var. *rotundifolia*, Makino (*S. media* var. *rotundifolia*, Nichols.). Lvs. broadly obovate or roundish obovate, $\frac{3}{4}$ – $1\frac{1}{2}$ in. long: fls. somewhat larger. G.C. II. 23:283; III. 37:149; 43:399. J.H.S. 33, p. 349. G. 29:663. G.M. 43:95. B.M. 7429. G.F. 7:305 (adapted in Fig. 3662).—Desirable hardy shrub of vig-

orous growth with showy umbels of pure white fls. and dark green handsome foliage remaining green until late in fall.

11. *Blumei*, Don (*S. rupestris*, Sieb.). Shrub, 4 ft. high, with spreading and arching branches: lvs. ovate to rhombic-ovate, incisedly crenate-serrate, pale bluish green beneath and rather prominently veined, $\frac{3}{4}$ – $1\frac{3}{4}$

3662. *Spiraea nipponica*. (× nearly 1)

in. long: fls. polygamous, white, in many-fl. umbels; petals roundish-obovate, about as long as stamens: follicles with spreading or reflexed styles. June. Japan. B.H. 8:36.—Not hardy N., rare in cult.; often the following or other species are met with under its names.

12. *trilobata*, Linn. (*S. triloba*, Linn.). Fig. 3663. Shrub, 4 ft. high, with slender spreading branches: lvs. almost orbicular, incised-dentate and often 3-lobed, obtuse, pale bluish green beneath, $\frac{1}{2}$ –1 in. long: fls. pure white, in many-fl. umbels; sepals upright in fr.: follicles with ascending styles. May, June. N. China to Siberia and Turkestan. L.B.C. 13:1271. G.F. 1:452. F.E. 30:45 (as *S. crataegifolia*).—Handsomely bushy shrub, quite hardy; cult. under many different names as *S. aquilegifolia*, *S. adiantifolia*, *S. crataegifolia*, *S. Blumei*.

13. *Vanhoùttei*, Zabel (*S. cantoniensis* × *S. trilobata*. *S. aquilegifolia* var. *Vanhoùttei*, Briot). Fig. 3664. Shrub, 6 ft. high, with arching branches: lvs. rhombic-ovate or rhombic-obovate, rounded or somewhat narrowed at the base, acute, incised-serrate, dark green above, pale bluish green beneath, $\frac{3}{4}$ – $1\frac{3}{4}$ in. long: fls. white, $\frac{1}{2}$ in. across, in many-fl. umbels; petals twice as long as stamens; sepals upright or spreading in fr. May, June. Of garden origin. Gn. 53, p. 251; 71, p. 334. Gn.M. 1:116; 3:131. G. 27:94. F.R. 10:133. F.E. 14:389; 17:673; 31:600. C.L.A. 4:210. G.F. 2:317. Gng. 5:210. A.G. 15:297. P.G. 3:173. M.D.G. 1900:17.—This is one of the most beautiful, or perhaps the most beautiful, of the early-blooming spireas and quite hardy. Sometimes confounded with the foregoing, which is similar but smaller in every part and less showy.

14. *cantoniensis*, Lour. (*S. Reevesiana*, Lindl. *S. lanceolata*, Poir. *S. corymbosa*, Roxbg.). Shrub, 4 ft. high, with slender, arching branches: lvs. rhombic-lanceolate, incisedly doubly serrate, dark green above,

pale bluish green beneath, 1-2½ in. long: fls. over ½ in. across, in rather dense umbels; sepals upright in fr.: follicles with spreading styles. May, June. China, Japan. B.R. 30:10. A.G. 18:356. G. 34:441.—Very handsome shrub, with large pure white fls., but only half-hardy N. Var. *lanceata*, Zabel (*S. Reevesiana flore-pleno*, Hort.), with double fls. and narrower lvs. is still more tender. H.F. 1855:11. This species and the three foregoing are valuable also for their handsome foliage, which remains fresh and green until late in fall.

15. *blanda*, Zabel (*S. chinensis* × *S. cantoniensis*. *S. Reevesiana robusta* or *nova*, Hort.). Upright shrub, 6 ft. high, with arching branches: lvs. oblong to ovate, acute at both ends, incised-serrate, dark green and almost glabrous above, grayish-tomentose beneath, 1-1½ in. long: fls. rather large, pure white, in pubescent umbels; sepals ovate-lanceolate, upright in fr.: follicles pubescent, with spreading styles. May, June. Of garden origin.—Only half-hardy North.

16. *chinensis*, Maxim. (*S. pubescens*, Lindl.). Upright shrub, 5 ft. high, with arching branches, tomentose when young: lvs. long-petioled, ovate, incised-serrate and sometimes 3-lobed, finely pubescent above, yellowish tomentose beneath, 1-2 in. long: fls. pure white, about ½ in. across, in pubescent umbels; sepals upright in fr., ovate-lanceolate, tomentose like the follicles; styles terminal, spreading. May. China. B.R. 33:38.—Handsome, but not hardy North.

17. *pubescens*, Turcz. Upright shrub, 6 ft. high, with slender, arching branches: lvs. similar to those of the foregoing species, but more grayish tomentose beneath and somewhat smaller, petioles shorter: fls. ¼-½ in. across, in glabrous umbels; sepals triangular-ovate, upright in fr.: follicles glabrous, with the spreading styles below the apex. May. N. China. G.F. 1:331.—Hardy N., and the large-fl. form as handsome as the foregoing species.

18. *media*, Schmidt (*S. confusa*, Regel & Koern.). Upright shrub, 5 ft. high, with terete branches, glabrous or pubescent when young: lvs. ovate to oblong,

3663. *Spiraea trilobata*.
(× ½)

cuneate at the base, incisedly serrate above the middle, almost glabrous or pubescent, 1-2½ in. long: fls. in many-fl. rather long-stalked, umbel-like racemes: follicles with the spreading or reflexed styles somewhat below the apex. May. S. E. Eu. to Japan. J.H. III. 46:533. G. 30:45. G.M. 49:504. R.F.G. 24:149. Var. *glabrescens*, Simonkai. Almost glabrous. Var. *subintegerrima*, Zabel (*S. oblongifolia*, Waldst. & Kit.). Lvs. elliptic-oblong to oblong-lanceolate, narrowed at

both ends, entire or with 1-3 teeth at the apex, nearly glabrous. Var. *sericea*, Regel (*S. sericea*, Turcz.). Lvs. pubescent on both sides.

19. *chamædryfolia*, Linn. Shrub, to 6 ft., with angular glabrous branchlets: lvs. slender-petioled, ovate, incisedly or doubly serrate from below the middle, almost glabrous, bluish green beneath, 1½-3 in. long: umbels many-fl., the lower ones on branchlets about 2 in. long, the upper ones often almost sessile; fls. about ½ in. across: follicles with the style upright and terminal. May, June. S. E. Eu. to Japan. G. W. H. 83. Var. *ulmifolia*, Maxim. (*S. ulmifolia*, Scop.). Lvs. more rounded at the base: umbels more elongated-hemispherical. S. E. Eu. R.F.G. 24:150. Var. *transiens*, Zabel. Lvs. narrower, oblong-ovate.—This and the preceding species spread by suckers.

3664. *Spiraea Vanhouttei*.

20. *flexuosa*, Fisch. (*S. chamædryfolia* var. *flexuosa*, Maxim.). Similar to the preceding species, but lower and more spreading: branchlets slender, strongly angled, distinctly zigzag: lvs. oblong-ovate to lance-oblong, cuneate at the base, usually serrate above the middle only, 1-2 in. long: umbels few-fl., short-stalked. May, June. N. E. Asia. Var. *stenophylla*, Schneid. (*S. chamædryfolia* var. *stenophylla*, Zabel). Lvs. smaller and narrower, usually less than 1 in. long.

Section II. CALOSPIRA. Species Nos. 21-42.

- A. Corymbs on usually short lateral branchlets along the mostly arching branches of the previous year.
- B. Lvs. ½-1 in. long, crenate-serrate, or serrate only at the apex: corymbs on very short branchlets.
- C. Branchlets angular: lvs. generally oval, obtuse: winter buds with 2 outer scales.....21. *canescens*
- CC. Branchlets terete: lvs. generally oblong: winter buds with several scales.....22. *Sargentiana*
- BB. Lvs. ¾-3 in. long.
- C. Fls. perfect, white.
- D. Winter buds short, ovate, with several outer scales: lvs. entire or dentate only above the middle.
- E. Upper surface of lvs. glabrous; margin entire: flowering branchlets 2-3 in. long..23. *Veitchii*
- EE. Upper surface of lvs. more or less pubescent, margin usually dentate toward the apex.
- F. Infl. glabrous.....24. *Wilsonii*
- FF. Infl. pilose.....25. *Henryi*
- DD. Winter buds elongated, pointed, with 2 outer scales: lvs. doubly or incisedly serrate.
- E. Foliage pubescent on the veins below, incisedly serrate.26. *Rosthornii*
- EE. Foliage glabrous, lvs. deeply serrate.....27. *longigemmis*
- CC. Fls. diaceous, pink or white: lvs. sharply serrate; winter buds ovate, with several scales.
- D. Shoot angular: lvs. usually ovate-oblong: fls. pink.....28. *bella*
- DD. Shoot terete: lvs. usually ovate to elliptic: fls. white.....29. *expansa*
- AA. Corymbs terminal on upright shoots of the year.

- B. Infl. pubescent, rarely glabrous, very compound, besides the terminal corymb lateral ones blooming somewhat later appear beneath it, only weak branches with a single corymb.**
- C. Shrub 1 ft. or less high, with bullate lvs. less than 1 in. long. 30. bullata**
- CC. Shrubs 1-5 ft. high, with larger lvs.**
- D. Branches terete.**
- E. Ripe follicles diverging. 31. japonica**
- EE. Ripe follicles upright, straight.**
- F. Fls. pink. 32. Margaritæ**
- FF. Fls. whitish or blushed. 33. Foxii**
- DD. Branches more or less angular, rather stiff, almost glabrous.**
- E. Color of fls. pink, rarely whitish. 34. Bumalda**
- EE. Color of fls. white. 35. albiflora**
- BB. Infl. consisting of only one terminal corymb, usually glabrous: follicles not diverging.**
- C. Corymbs usually pubescent.**
- D. Sepals reflexed in fr.: lvs. generally oblong, acute, or acuminate: fls. pink or whitish. 36. superba**
- DD. Sepals upright in fr.: lvs. generally ovate or oval: fls. white. 37. corymbosa**
- CC. Corymbs glabrous (often puberulous in No. 41).**
- D. Stamens longer than the petals.**
- E. Fls. pink; annular disk wanting. 38. densiflora**
- EE. Fls. white; disk present.**
- F. Lvs. oblong, entire, or with few teeth above the middle, acute. 39. virginiana**
- FF. Lvs. oval or elliptic, toothed.**
- G. Margin of lvs. sharply, often doubly serrate, apex acutish. 40. lucida**
- GG. Margin of lvs. crenate-dentate, apex rounded. 41. betulifolia**
- DD. Stamens as long as petals: decumbent shrub: lvs. $\frac{1}{2}$ -1 in. long, sharply serrate. 42. decumbens**

21. canescens, D. Don. Shrub, 6 or sometimes 12 ft. high, with spreading and arching branches; branchlets angled: lvs. broadly oval to obovate, very short-petioled, crenately dentate above the middle, grayish green, pubescent beneath or sometimes almost glabrous at length, $\frac{1}{2}$ - $\frac{3}{4}$ in. long; fls. white, rather small, in dense, semi-globose corymbs to 2 in. across, appearing very profusely along the branches; stamens about as long as petals; sepals upright or spreading in fr.: follicles villous, with the ascending styles a little below the apex. July. Himalayas. Gn. 45, p. 49; 49, p. 421; 52, p. 28; 54, p. 48; 61, p. 380; 62, p. 414. G.C. III. 43:90.—Very graceful and handsome shrub, but not hardy N. It occurs under very many different names in the gardens, as *S. cuneata*, *S. cuneifolia*, *S. flagellata*, *S. flagelliformis*, *S. rotundifolia*, *S. vacciniifolia*, and others. Var. *myrtifolia*, Zabel (*S. argentea*, Hort.). Lvs. dark green above, glaucous and less pubescent below, narrower. M.D.G. 1906:385.

22. Sargentiana, Rehd. Shrub, to 6 ft., with slender spreading branches; branchlets terete, puberulous at first, soon glabrous: lvs. elliptic-oblong to obovate-oblong, narrowed into the petiole, with a few acute teeth at the apex, rarely entire, puberulous above, villous beneath chiefly on the veins, $\frac{1}{2}$ -1 in. long; corymbs dense, 1-1 $\frac{1}{4}$ in. across, villous: fls. white, $\frac{1}{4}$ in. across; calyx villous; stamens about as long as petals: carpels nearly glabrous. June. W. China.—A very graceful shrub, similar to *S. canescens*; has proved not quite hardy at the Arnold Arboretum.

23. Veitchii, Hemsl. Shrub, to 12 ft., with spreading and arching branches; branchlets puberulous while

young, reddish, striped: lvs. oval to oblong, rarely obovate, obtuse, cuneate at the base, entire, finely puberulous beneath and glaucous, glabrous above, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long; corymbs 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ in. across, puberulous: fls. $\frac{1}{2}$ in. across, white; calyx puberulous; stamens longer than petals: carpels glabrous, upright. June, July. B.M. 8383. J.H.S. 35, p. 152, fig. 98. G.M. 52:598.—Like the two following closely allied species very handsome and hardy as far north as Mass.

24. Wilsonii, Duthie. Shrub, to 8 ft., with arching branches; branchlets dull purplish, pubescent while young: lvs. very short-petioled, oval to oblong or obovate, obtuse or acutish, cuneate at the base, entire or with a few coarse teeth at the apex, dull green and pubescent above, grayish green and villous beneath, particularly on the veins, $\frac{3}{4}$ -2 $\frac{1}{4}$ in. long; corymbs dense, 1 $\frac{1}{2}$ -2 in. across, glabrous or nearly so: fls. $\frac{1}{4}$ in. across, pure white; calyx glabrous: follicles sparingly pilose, slightly spreading. June. Cent. and W. China. B.M. 8390. G. 35:851.

25. Hénryi, Hemsl. Fig. 3665. Shrub, to 8 ft., with spreading branches; branchlets sparingly pilose or nearly glabrous: lvs. obovate or oblong to oblanceolate, cuneate at the base, acute or rounded at the apex, usually coarsely dentate toward the apex, slightly hairy above, villous beneath particularly on the veins, $\frac{3}{4}$ -3 in. long; petiole $\frac{1}{6}$ - $\frac{1}{4}$ in. long; corymb 2 in. across, rather loose, pilose: fls. $\frac{1}{4}$ in. across; stamens shorter than petals: follicles hairy, slightly spreading. June. Cent. and W. China. B.M. 8270. Gn. 65, p. 44. J.H.S. 28:62, fig. 20. G. 37:35. Var. *notabilis*, Farquhar. Corymbs larger.

26. Rösthornii, Pritz. (S. Pratii, Schneid.). Shrub, to 6 ft., with spreading branches; branchlets yellowish brown, sparingly hairy while young: winter buds elongated, long-pointed, often as long as petiole: lvs. ovate to ovate-oblong, acuminate, cuneate at the base, rarely nearly rounded, incisely serrate, bright green, hairy on the veins beneath, 1 $\frac{1}{2}$ -3 in. long; petioles $\frac{1}{4}$ - $\frac{1}{2}$ in. long; corymbs rather loose, 2-3 in. across, pilose, on elongated branchlets: fls. $\frac{1}{4}$ in. across, white, stamens longer than petals. June. W. China.—A graceful shrub with handsome bright green foliage.

27. longigemma, Maxim. Fig. 3666. Shrub, 4 ft. high, with slender terete branches, glabrous: axillary buds acuminate, longer than the petioles: lvs. ovate-lanceolate to oblong-lanceolate, incisely and doubly serrate, with glandular-tipped teeth, bright green, glabrous, 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ in. long; fls. white in rather loose 2-3-in. broad pubescent corymbs; sepals spreading in fr.: follicles almost glabrous, with terminal spreading styles. June. N. W. China. G.F. 7:345 (adapted in Fig. 3666) I.T. 5:92. G. 34:443.—Hardy.

28. bella, Sims (S. expansa, Wall. S. ovata, and S. coccinea, Hort.). Shrub, 3 ft. high, with slender, spreading branches, angular and sparingly pubescent: lvs. ovate-elliptic to ovate-lanceolate, acute at both ends, sharply serrate from below the middle, almost glabrous, whitish or bluish green beneath, 1-2 in. long; fls. dioecious, $\frac{1}{2}$ in. across, pink, in small corymbs, $\frac{1}{2}$ -2 in.

3665. *Spiraea Henryi*. ($\times \frac{1}{4}$)

across; stamens little longer than petals; sepals reflexed in fr.: follicles pubescent only at the inner suture, with spreading styles. June, July. Himalayas. B.M. 2426. L.B.C. 13:1268.—Only half-hardy North.

29. *expansa*, Koch (*S. bella* var. *expansa*, Regel. *S. fastigiata*, Wall.). Closely allied to the foregoing; more vigorous and upright, 6 ft. high, with terete branches tomentose when young: lvs. ovate to ovate-oblong,

3666. *Spiraea longigemmis*.
($\times \frac{3}{8}$)

acute at both ends, sharply serrate from the middle, usually pubescent on the veins beneath, $1\frac{1}{2}$ –3 in. long: fls. white, $\frac{1}{4}$ in. across, in 1–4-in.-broad corymbs terminal on upright, often very long branches: follicles pubescent, diverging. July. Himalayas.—*S. pulchella*, Kunze (*S. kumaonensis*, Hort.), is supposed to be a hybrid of this and the foregoing species; it combines the broader corymbs of the latter with the brighter color of the first species, therefore handsomer than either parent; sometimes cult. as *S. expansa rubra*, but there is also another hybrid of the same name. See *S. rubra* in suppl. list.

30. *bullata*, Maxim. (*S. crispifolia*, Hort.). Dwarf shrub, with strictly upright, brown, villous branches: lvs. roundish-ovate to ovate, very short-petioled, incisely serrate, thickish and bullate, almost glabrous, grayish green beneath, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: fls. deep pink, in small and dense corymbs $1\frac{1}{2}$ –3 in. across. July, Aug. Japan. Gt. 35:1216.

31. *japonica*, Linn. (*S. callosa*, Thunb.). Shrub, 4 ft. high, with upright branches glabrous or puberulous when young: lvs. ovate to oblong-lanceolate, acute at both ends or acuminate, doubly and incisely serrate, pale bluish green and usually glabrous beneath, 1–4 in. long: fls. small, pale to deep pink, in usually much-compound and rather loose corymbs; sepals reflexed in fr.: follicles glabrous, diverging with ascending styles. June, July. Japan, China.—A very variable species. The variety most common in cult. usually under the name *S. callosa* is var. *Fórtunei*, Rehd. (*S. Fórtunei*, Planch. *S. callosa*, Lindl., not Thunb.). Higher, with quite terete branches: lvs. 2–4 in. long, oblong-lanceolate, acuminate, sharply and doubly serrate, with incurved, callous-tipped teeth, rugose above, bluish white beneath: corymbs very compound, rather loose; disk less developed, sometimes wanting. E. and Cent. China. F.S. 9:871. B.M. 5164. B.H. 8:129.—Handsome shrub with the young unfolding lvs. of a pretty purplish color and very large much-compound corymbs. The Japanese forms grow less high, have smaller and

broader, coarsely doubly dentate-serrate lvs., not rugose and less whitish beneath; the sts. are slightly striped by the decurrent petioles and the infl. is less compound. Other varieties of Chinese origin are the two following recently intro. varieties. Var. *acuminata*, Franch. Lvs. ovate-oblong to lanceolate, acuminate, green and pubescent beneath, at least on the veins, 2–3½ in. long: fls. pink, in terminal corymbs 4–6 in. across. Cent. and W. China. Var. *ovalifolia*, Franch. Lvs. oval to elliptic, acute, glabrous and glaucescent beneath, $1\frac{1}{2}$ –3 in. long: fls. white, in corymbs 3–5 in. across. W. China.—Japanese forms little known in cult. are var. *pubescens*, Regel, with the lvs. pubescent beneath and the corymbs pubescent, and var. *glabrata*, Nichols. (*S. glabrata*, Lange), with ovate glabrous lvs. and bright pink fls. in glabrous corymbs. The following are garden forms: Var. *atrosanguinea*, Zabel. Fls. deep pink, in tomentose corymbs. Var. *ruberrima*, Zabel. Fls. deep pink, in puberulous corymbs. Var. *macrophylla*, Simon-Louis. Lvs. becoming 6 in. long, bullate: corymbs small. Var. *variegata*, Hort. Lvs. variegated with yellowish white. Most of the other forms enumerated as varieties under this species are hybrids.

32. *Margaritæ*, Zabel (*S. japonica* $\times$ *S. superba*). Shrub, 5 ft. high, puberulous: lvs. ovate-elliptic to elliptic, coarsely and often doubly serrate, pubescent on the midrib beneath and pale green, 2–3 in. long: fls. rather large, bright pink, in broad corymbs; sepals spreading in fr.: follicles upright, glabrous, with upright styles. July, Aug. Of garden origin.—Handsomeness, very free-flowering form.

33. *Fóxi*, Zabel (*S. corymbosa* $\times$ *S. japonica*). Similar to the preceding: branches more or less striped, almost glabrous: lvs. elliptic, doubly serrate, glabrous: fls. whitish or pinkish, in large, puberulous corymbs; styles spreading in fr. June, July. R. H. 1900, p. 117. Of garden origin.—Less desirable than the preceding hybrid.

34. *Bumálda*, Burvenich (*S. japonica* $\times$ *S. albiflora*, *S. pumila*, Zabel). Shrub, 2 ft. high, rarely higher: lvs. ovate-lanceolate, sharply and doubly serrate, glabrous, 2–3 in. long: fls. whitish to deep pink: follicles diverging. July, Aug. B.H. 17:12. Gn. 46, p. 416. Mn. 2, p. 24. G.C. III. 43:416.—Cult. in many different forms, probably all of garden origin. Two of the best are var. *Anthony Waterer*, a very free-flowering, compact shrub with bright crimson fls. in rather

3667. *Spiraea albiflora*. ($\times \frac{1}{4}$)

dense corymbs and rather narrow, incisely serrate lvs. Gn. 45:49. G.C. III. 14:365; and var. *Frœbeli*, Hort. (*S. callōsa* var. *Frœbeli*, Hort.), a taller plant with broader, ovate-oblong lvs. and also with bright crimson fls. F.E. 31:604. A similar form is *S. Lemōinei*, Zabel (*S. Bumalda* var. *ruberrima*, Hort.), hybrid of *S. Bumalda* and *S. bullata*, a low, compact shrub, with somewhat bullate lvs. and pink fls.

3668. *Spiraea latifolia*. ($\times \frac{1}{2}$)

35. *albiflora*, Miq. (*S. japonica alba*, Regel. *S. leucantha*, Lange). Fig. 3667. Low shrub, $1\frac{1}{2}$ ft. high, with stiff, upright branches: lvs. lanceolate, coarsely or sometimes doubly serrate, glabrous, 1-2 in. long: fls. white, in dense corymbs, one large terminal and many smaller ones below along the branch; disk prominent; sepals reflexed in fr.: follicles upright, not or little diverging. July, Aug. Japan.

36. *superba*, Zabel (*S. albiflora* $\times$ *S. corymbosa*). Low shrub, with striped dark brown branches: lvs. elliptic-oblong to oblong, acute at both ends, simply or doubly serrate, almost glabrous, 1-3 in. long: fls. rather large, pink or almost whitish; disk prominent; petals orbicular or broadly obovate. June, July. Of garden origin.

37. *corymbosa*, Raf. (*S. crataegifolia*, Link). Low shrub, with usually little-branched sts., rarely to 3 ft. high: branches purplish brown: lvs. broadly oval to ovate, acutish, coarsely and often doubly serrate, especially above the middle, pale bluish green beneath and

glabrous, $1\frac{1}{2}$ -3 in. long: fls. white, rather small, in somewhat convex usually pubescent corymbs, $1\frac{1}{2}$ -3 in. across; petals oval: follicles and styles upright. May, June. N. J. to Ga. and Ky. L.B.C. 7:671. G.O.H. 82. B.B. (ed. 2) 2:246.

38. *densiflora*, Nutt. (*S. betulifolia* var. *rosea*, Gray. *S. splendens*, Baumann. *S. rosea*, Koehne. *S. arbuticula*, Greene). Low, much-branched shrub: lvs. very short-petioled, oval to ovate, obtuse, crenately serrate, glabrous, rarely sparingly puberulous beneath, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long: fls. bright pink, in dense corymbs 1-2 in. across. June-Aug. Brit. Col. to Ore., Wyo., and Mont. G.F. 10:413.

39. *virginiana*, Brit. Much-branched shrub, to 4 ft., glabrous: lvs. lance-oblong, acute, cuneate or rounded at the base, entire or with a few teeth above the middle, pale or glaucescent beneath, $1\frac{1}{2}$ -2 in. long: fls. white, in dense glabrous corymbs, about 2 in. across. June. Va. to N. C. and Tenn. B.B. (ed. 2) 2:246.

40. *lucida*, Douglas (*S. corymbosa* var. *lucida*, Zabel). Closely allied to *S. corymbosa*: branches yellowish brown or brown: lvs. more incisely serrate, oval or obovate: corymb glabrous, usually looser and more flat, broader. June, July. Brit. Col. to Sask., Wyo. and Ore.

41. *betulifolia*, Pall. Low, much-branched shrub: lvs. oval to obovate-oblong, usually cuneate at base and very short-petioled, serrate or crenately serrate, obtuse, glabrous or slightly pubescent on the veins beneath, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long: corymb usually glabrous, 1-2 in. across. June, July. Siberia to Manchuria, Kamchatka and Japan.—The three preceding species except *S. virginiana* are all closely allied and considered by some botanists varieties of *S. betulifolia*.

42. *decumbens*, W. Koch (*S. procumbens*, Hort.). Dwarf, procumbent shrub, about $\frac{1}{2}$ ft. high, with ascending branches, glabrous: lvs. elliptic to oblong, acute at both ends, crenately serrate above the middle, glabrous, $\frac{1}{2}$ -1 in. long: fls. white, in small corymbs, about 2 in. across: follicles glabrous, with upright terminal styles. June. Tyrol. G.C. II. 11:752. M.D.G. 1912:186. R.F.G. 24:151. G.M. 57:746.—Pretty shrub for rockeries.

SECTION III. SPIRÆA. Species Nos. 43-55.

- A. Infl. a broad panicle, about as broad as high. (Hybrids of species of this and the preceding section.)
- B. Panicles rather small, on lateral branchlets at the end of last year's branches.....43. *Fontenaysii*
- BB. Panicles large, terminal on long, upright branches.
- C. Lvs. glabrous or nearly so.
- D. Apex of lvs. acute.....44. *conspicua*
- DD. Apex of lvs. obtuse or acutish.
- E. Shape of lvs. broadly ovate or obovate.....45. *notha*
- EE. Shape of lvs. oblong or oval-oblong.....46. *pyramidata*
- CC. Lvs. pubescent or tomentose beneath.
- D. Base of lvs. acute.....47. *sanssouciana*
- DD. Base of lvs. rounded.....48. *Watsoniana*
- AA. Infl. an elongated panicle, longer than broad. (*Spiræa* proper.)
- B. Foliage glabrous or nearly so.
- C. Lvs. sharply serrate, except at the very base.
- D. Panicles tomentulose.
- E. Fls. light pink.....49. *salicifolia*
- EE. Fls. white.....50. *alba*
- DD. Panicles glabrous.....51. *latifolia*
- CC. Lvs. coarsely serrate above the middle: fls. pink.....52. *Menziesii*
- BB. Foliage pubescent or tomentose beneath.
- G. Follicles glabrous: lvs. grayish or whitish tomentose beneath.

- d. *Lvs. acute at both ends*.....53. *Billiardii*
 DD. *Lvs. rounded or nearly so at both ends*.....54. *Douglasii*
 CC. *Follicles pubescent; lvs. usually light tawny beneath*.....55. *tomentosa*

43. *Fontenaysii*, Billiard (*S. fontenaysiensis*, Dipp. *S. canescens* × *S. salicifolia*). Shrub, 6 ft. high, with slender, upright branches: lvs. oval or oblong-oval, rounded at both ends, crenately serrate above the middle, pale bluish green beneath, almost glabrous, 1-2 in. long: fls. white or pink, in $1\frac{1}{2}$ -3-in.-long panicles; petals orbicular, about as long as stamens; sepals spreading in fr. June, July. Of garden origin.—Not quite hardy N. Var. *álba*, Zabel, is the white-fl., var. *rosea*, Zabel, the pink-fl. form. *S. pruinosa*, Zabel (*S. brachybotrys*, Lange. *S. luxuriosa*, Hort. *S. canescens* × *S. Douglasii*), is a similar form, but the lvs. are tomentose beneath and the fls. pink.

44. *conspícua*, Zabel (*S. albiflora* × *S. álba*). Upright shrub, 3 ft. high, with dark brown puberulous branches: lvs. elliptic-oblong, acute at both ends, simply or doubly serrate, almost glabrous, $1\frac{1}{2}$ -2½ in. long: fls. pinkish white, in broad finely pubescent panicles; petals shorter than stamens. July-Sept.—Handsome form. A similar hybrid is *S. syringæflora*, Lem. (*L. albiflora* × *S. salicifolia*), with oblong-lanceolate or lanceolate lvs., serrate above the middle, and pink fls. Closely allied is also *S. semperflorens*, Zabel (*S. japonica* × *S. salicifolia*, *S. japonica* or *S. Fortunei* var. *paniculata*, Hort.). Higher than the former: lvs. oblong-lanceolate, usually doubly serrate: fls. pink. R.H. 1860, pp. 496, 497. Gn. 45, p. 48. G. 3:191.

45. *nôtha*, Zabel (*S. corymbosa* × *S. latifolia*). Shrub, 3 ft. high, with brown, glabrous branches: lvs. broadly ovate to obovate, short-petioled, coarsely and doubly serrate, almost glabrous, 1-2 in. long: fls. white to pinkish white, in broad, glabrous panicles; stamens almost twice as long as the orbicular petals. July, Aug.—Of garden origin.

46. *pyramidata*, Greene. Possibly hybrid between *S. lucida* and *S. Menziesii*. Upright shrub, 3 ft. high: lvs. oval-oblong to oblong, acutish or obtuse, usually doubly serrate above the middle, glabrous or nearly so, $1\frac{1}{2}$ -3 in. long: panicles $1\frac{1}{2}$ -3½ in. long, rather dense, puberulous: fls. pinkish or almost white. July. Found wild in Ore. and Wash.

47. *sanssouciâna*, Koch (*S. Douglasii* × *S. japonica*. *S. Regeliana*, Hort. *S. Nobleana*, Hook.). Shrub, 4 ft. high, with striped, finely tomentose branches: lvs. oblong-lanceolate, sharply and usually doubly serrate, grayish tomentose beneath, 2-3½ in. long: fls. pink, in broad corymb-like panicles: follicles glabrous, with spreading styles. July, Aug. Of garden origin. B.M. 5169. I.H. 8:286.—An allied form is *S. intermedia*, Lemoine (*S. albiflora* × *S. Douglasii*), similar in habit to *S. syringæflora* but with the lvs. tomentose beneath.

48. *Watsoniâna*, Zabel (*S. Douglasii* var. *Nobleana*, Wats. *S. Nobleana*, Zabel. *S. Douglasii* × *S. densiflora*). Shrub, 4 ft. high, similar to the former: lvs. oblong or narrowly oblong, usually rounded at the base, acute, sharply serrate above the middle, grayish-tomentose beneath, 1-3 in. long: fls. light pink, in dense broadly pyramidal, tomentulose panicles 3-6 in. high; petals half as long as stamens; sepals reflexed in fr.; styles erect. June, July. Natural hybrid, found in Calif. *S. subvillosa*, Rydb., apparently belongs here.—A similar form is *S. pachystachys*, Zabel (*S. corymbosa* × *S. Douglasii*), with broader lvs. and fls. of paler pink. G.C. III. 38:322.

49. *salicifolia*, Linn. (*S. sibirica*, Raf. *S. salicifolia* var. *carnea*, Ait.). Upright shrub, 5 ft. high, with terete yellowish brown branches puberulous when young; lvs. oblong-lanceolate to lanceolate, sharply and sometimes doubly serrate with often incurved teeth,

$1\frac{1}{2}$ -3 in. long: fls. light pink or whitish, in oblong, dense, tomentulose panicles leafy below, the lvs. exceeding the ascending ramifications; stamens twice as long as petals; sepals upright in fr.: follicles ciliate at the inner suture. June, July. S. E. Eu. to Japan and probably Alaska. R.F.G. 24:152. G.W.H. 82. Var. *grandiflora*, Dipp. (*S. grandiflora*, Lodd.). Lower, with larger, lighter pink fls. L.B.C. 20:1988.

50. *álba*, Dur. (*S. salicifolia* var. *paniculata*, Ait. *S. lanceolata*, Borkh.). QUEEN OF THE MEADOW. MEADOW-SWEET. Attractive upright shrub, attaining 6 ft., with reddish brown branches puberulous when young: lvs. narrow, oblong to oblanceolate, acute, usually regularly simply serrate, $1\frac{1}{2}$ -2½ in. long: fls. white, in leafy

pyramidal tomentulose panicles, the lower spreading ramifications much longer than their supporting lvs.; stamens white, usually as long as petals: follicles quite glabrous. June-Aug. From N. Y. west to Mo., south to Ga. and Miss. B.B. (ed. 2) 2:245.—Also known as *S. salicifolia*.

51. *latifolia*, Borkh. (*S. salicifolia* var. *latifolia*, Ait. *S. carpini-folia*, Willd. *S. canadensis*, Hort. *S. bethlehemensis*, Hort.). QUEEN OF THE MEADOW. MEADOW-SWEET. Fig. 3668. Branching shrub, 2-5 ft. high, with bright or dark red-brown glabrous twigs: lvs. broadly oval to obovate or oblong, usually coarsely and often doubly serrate, $1\frac{1}{2}$ -3 in. long: fls. white, larger than those of *S. álba*, sometimes slightly blushed and with the stamens and disk more or less pinkish; panicles

3669. *Spiraea Douglasii*. (× $\frac{1}{3}$)

quite glabrous, broadly pyramidal, with spreading and elongated ramifications; stamens longer than petals. June-Aug. Newfoundland and Canada to N. C. Em. 2:485. G.C. III. 43:417.—This and the preceding species have been referred by most American botanists to *S. salicifolia*. *S. álba* is chiefly found west, *S. latifolia* east of and on the Alleghanies, while the true *S. salicifolia* is an Old-World species.

52. *Menziesii*, Hook. (*S. Douglasii* var. *Menziesii*, Presl). Upright shrub, 4 ft. high, with brown, at first puberulous, branches: lvs. oblong-obovate to oblong, coarsely and unequally serrate above the middle, pale green beneath, $1\frac{1}{2}$ -3 in. long: fls. small, pink, in rather narrow, 5-8-in.-long panicles; stamens more than twice as long as the roundish petals; sepals reflexed in fr. June-Aug. Alaska to Ore.

53. *Billiardii*, Herincq (*S. Douglasii* × *S. salicifolia*). Shrub, 6 ft. high, with brown pubescent branches: lvs. oblong to oblong-lanceolate, acute, sharply and often doubly serrate, except in the lower third, usually grayish-tomentose beneath, at least when young, sometimes almost glabrous at length, 2-3 in. long: fls. bright pink, in 5-8-in. long, tomentose or tomentulose panicles usually rather narrow and dense. July, Aug. Of garden origin. H.F. 5:24. F.E. 18:613.—*S. Lenneana*, *S. bethlehemensis rubra*, *S. triumphans*, *S. ezimia*, *S. Constantiz*, *S. californica*, Hort., are very similar and probably of the same parentage.

54. *Douglasii*, Hook. Fig. 3669. Shrub, 8 ft. high, with reddish brown, tomentose branches: lvs. oblong to narrow-oblong, rounded or acutish at both ends, unequally serrate above the middle, densely white-tomentose beneath, 1½-4 in. long: fls. deep pink, in dense, rather narrow or sometimes broad panicles, 4-8 in. long; stamens twice as long as the obovate petals; sepals reflexed in fr.: follicles glabrous. July, Aug. Brit. Col. to Calif. F.S. 2:66. R.H. 1846:101. P.M. 12:195. B.M. 5151. Gn. 23:246.

55. *tomentosa*, Linn. HARDHACK. STEEPLEBUSH. Shrub, 4 ft. high, with upright, brown, tomentose branches: lvs. ovate to oblong-ovate, acute, unequally and often doubly serrate, densely yellowish or grayish-tomentose beneath, 1-2½ in. long: fls. deep pink or purple, in narrow dense panicles, brownish tomentose and 3-8 in. long; stamens somewhat longer than the obovate petals; sepals reflexed: follicles pubescent, usually diverging. July-Sept. Nova Scotia to Ga., west to Man. and Kans. B.B.(ed. 2) 2:245. Em. 2:485. Gn.M. 5:344. Var. *alba*, Rehd. (f. *albiflora*, Macbride). With white fls. F.E. 8:833. Gng. 5:149.—This species does not spread by suckers like most others of the section *Spiraria*. All the last-named species are valuable as late-blooming shrubs and decorative with their showy panicles of bright or deep pink fls. They appear at their best when planted in masses in the wilder parts of the park in low ground.

S. Aitchisonii, Hemsl.—*Sorbaria Aitchisonii*.—*S. amurensis*, Maxim.—*Physocarpus amurensis*.—*S. arifolia*, Smith.—*Holodiscus discolor* var. *arifolius*.—*S. Arincus*, Linn.—*Aruncus sylvestris*.—*S. asmilis*, Zabel (S. densiflora × S. japonica). Low shrub, with pink fls. in broad corymb-like panicles. Garden hybrid. —*S. astilboides*, Moore.—*Astilbe astilboides*.—*S. Boursieri*, Carr.—*Holodiscus Boursieri*.—*S. brumalis*, Lange (probably *S. expansa* × *S. alba*). Medium-sized shrub, with oblong, incisely serrate, almost glabrous lvs. and pinkish white fls. in broad and loose corymb-like panicles. Aug.-Oct. Garden hybrid. —*S. cespitosa*, Nutt.—*Petrophytum cespitosum*.—*S. calceola*, W. W. Smith. Shrub to 5 ft., with slender arching branches: lvs. small, obovate or elliptic, entire, glabrous: fls. white, pink outside, in 6-8-fid. umbels. S. W. China. —*S. camtschatica*, Pall.—*Filipendula camtschatica*.—*S. capitata*, Pursh.—*Physocarpus capitatus*.—*S. cinerea*, Zabel (S. cana × S. hypericifolia). Medium-sized shrub, with small, oblong, usually entire, pubescent lvs. and white fls. in short-stalked umbels. Garden hybrid. —*S. conchra*, Zabel (S. albiflora × S. expansa). Medium-sized shrub, with lanceolate, sharply serrate, almost glabrous lvs. and pinkish white fls. in broad corymbs. Garden hybrid. —*S. compacta multiflora*, Hort.—*Astilbe japonica* var.—*S. conferta*, Zabel (S. cana × S. crenata). Medium-sized shrub, with small, ovate to oblong-lanceolate, 3-nerved, entire or crenate lvs. and white fls. in dense, small, peduncled umbels. Garden hybrid. —*S. dahurica*, Maxim., is closely allied to *S. alpina*, but not yet intro. *S. canescens* and *Sorbaria sorbifolia* are sometimes cult. under this name.—*S. dasycarpa*, Bunge. Allied to *S. chinensis*. Lvs. ovate, cuneate at the base, incisely serrate or lobed, with grayish white tomentum beneath: infl. grayish tomentose; stamens half as long as petals. N. China.—*S. Davidi*, Hort.—*Astilbe Davidi*.—*S. difformis*, Zabel (S. alba × S. corymbosa). Medium-sized shrub, with oval to oblong-lanceolate, serrate, almost glabrous lvs. and white fls. in large corymb-like panicles. Garden hybrid. —*S. digitata*, Willd.—*Filipendula palmata*.—*S. discolor*, Pursh.—*Holodiscus discolor*.—*S. dumosa*, Nutt.—*Holodiscus dumosus*.—*S. Filipendula*, Linn.—*Filipendula hexapetala*.—*S. fissia*, Lindl.—*Holodiscus fissus*.—*S. floribunda*. A trade name of indiscriminate meaning. *S. semperflorens* and *Sorbaria sorbifolia* are sometimes met with under this name.—*S. gemmata*, Zabel (S. mongolica, Hort., not Maxim.). Allied to *S. alpina*: axillary buds much longer than petioles: lvs. small, penninerved, oblong-lanceolate, usually entire: fls. white, in short-stalked, rather few-fid. umbels. Mongolia.—*S. Gieseleriana*, Zabel (S. cana × S. chamædryfolia). Medium-sized shrub, with ovate, sharply serrate lvs. and rather large white fls. in long-stalked umbels. Garden hybrid.—*S. gigantæa*, Hort.—*Filipendula camtschatica*.—*S. gracilis*, Maxim. (S. vacciniifolia, Lodd., not Don). Low shrub, allied to *S. canescens*, with

slender, arching branches: lvs. small, ovate, obtuse, entire or crenate above the middle, quite glabrous: fls. white, in hemispherical loose corymbs. Himalayas. L.B.C. 15:1403.—*S. grandiflora*, Sweet.—*Sorbaria grandiflora*.—*S. grandiflora*, Hook.—*Exochorda racemosa*.—*S. Hacquetii*, Fenzl & Koch. Closely allied to *S. decumbens*, but grayish-pubescent and with the sepals upright or spreading in fr. N. Italy, Tyrol.—*S. Hocheri*, garden name, applied to *S. nudiflora*, *S. bella*, *S. expansa*, *S. tristis*, and others, and also to *Exochorda racemosa*.—*S. Humboldtii*, Hort.—*Aruncus sylvestris*.—*S. inflata*, Koch (S. crenata × S. mollis). Medium-sized shrub, with slender arching branches: lvs. elliptic-oblong, entire, sparingly pubescent beneath: fls. white, rather large, in many-fid. stalked umbels. Garden hybrid.—*S. japonica*, Hort., not Linn. f.—*Astilbe japonica*.—*S. kamohensis spicata*, Hort., is a form of *S. semperflorens*.—*S. kamschatica*, Auth.—*Filipendula camtschatica*.—*S. levigata*, Linn.—*Sibiraea levigata*.—*S. laeviflora*, Lindl.—*S. vacciniifolia*.—*S. Lindleyana*, Wall.—*Sorbaria Lindleyana*.—*S. lobata*, Gronov.—*Filipendula rubra*.—*S. micropetala*, Zabel (S. hypericifolia × S. media). Medium-sized shrub, with grayish green, oblong-obovate lvs., entire or serrate at the apex, 3- or penninerved: fls. white or greenish white, in umbels on leafy or naked stalks. Garden hybrid.—*S. Millefolium*, Torr.—*Chamebataria Millefolium*.—*S. Miyabei*, Koizumi. Allied to *S. bella* and *S. japonica*. Lvs. ovate, incisely serrate, glabrous, 1½-2½ in. long; infl. 1½-2 in. long, puberulous: fls. white, perfect; stamens much longer than petals: follicles upright, style spreading. Japan. Var. *glabrata*, Rehd. Lvs. broadly cuneate at base: infl. glabrous. Cent. China. Var. *pilosula*, Rehd. Lvs. pubescent on the veins beneath: infl. sparingly pilose. Cent. China. This species is very similar to *S. chamædryfolia* in habit and foliage and also in the individual fls. but is easily distinguished by the compound corymb. Hardy at the Arnold Arboretum.—*S. mollifolia*, Rehd. Allied to *S. alpina* and *S. cana*. Spreading shrub, to 6 ft.: winter buds acuminate, 2-valved, longer than petioles: lvs. elliptic-oblong or oblong, entire or with few teeth at the apex, villous on both sides, ½-¾ in. long; infl. villous: fls. ¼ in. across, white: follicles upright, pubescent. W. China.—*S. mollis*, Koch (S. cana × S. media). Similar to *S. media*: lvs. smaller, usually entire, pubescent; fls. smaller, umbels pubescent. Garden origin.—*S. mongolica*, Maxim., is closely allied to *S. crenata*, but not yet intro.; the *S. mongolica* of gardens is *S. gemmata*.—*S. monogyna*, Torr. & Gray.—*Physocarpus monogynus*.—*S. myrtilloides*, Rehd. Allied to *S. alpina*. Shrub, to 8 ft.: lvs. oval to obovate-oblong, entire, obtuse, rarely acutish, cuneate at the base, slightly pubescent beneath, ½-¾ in. long; infl. dense, hemispherical, on short leafy branchlets: fls. white, ¼ in. across: follicles upright, glabrous. W. China. Very graceful shrub. —*S. nepalensis*, a garden name applied to several species, as *S. micropetala*, *S. canescens*, *S. salicifolia*.—*S. nivea*, Zabel (S. canescens × S. expansa). Similar to *S. canescens* in habit, corymbs larger and looser: lvs. coarsely doubly serrate, pubescent, 1-2 in. long; fls. white or pinkish white. Garden hybrid.—*S. nudiflora*, Zabel (S. bella × S. ulmifolia). Medium-sized shrub, with ovate, doubly serrate, almost glabrous lvs. and pinkish white fls. in hemispherical corymbs. Handsome, almost hardy shrub. Garden hybrid.—*S. opulifolia*, Linn.—*Physocarpus opulifolius*.—*S. oxyodon*, Zabel (S. chamædryfolia × S. media). Similar to *S. media*, but branches angular: lvs. narrower, follicles with the styles terminal and spreading. Garden hybrid.—*S. Pallasii*, Don.—*Sorbaria grandiflora*.—*S. palmata*, Pall.—*Filipendula palmata*, Linn.—*Filipendula palmata*, Thunb.—*Filipendula purpurea*.—*S. palmata*, Linn.—*Filipendula rubra*.—*S. parvifolia*, Bertol.—*S. gracilis*.—*S. pectinata*, Torr. & Gray.—*Luetkea pectinata*.—*S. revirescens*, Zabel (S. expansa × S. japonica). Medium-sized shrub, with oblong, coarsely serrate lvs., pubescent on the veins beneath: fls. light to deep pink, in large corymbs; blooming in summer and usually again in fall. Garden hybrid.—*S. ribifolia*, Nutt.—*Physocarpus capitatus*.—*S. rubra*, Zabel (S. ruberrima, Dipp. S. Douglasii × S. expansa). Upright medium-sized shrub, with oblong-lanceolate, coarsely serrate lvs. tomentose beneath, and deep pink fls. in ovate panicles. Garden hybrid.—*S. Schnabeckii*, Zabel (S. chamædryfolia × S. trilobata). Medium-sized shrub, with arching branches: lvs. ovate to oblong-ovate, doubly serrate, glabrous: fls. white, rather large, in peduncled umbels; petals longer than stamens. Handsome shrub, similar to *S. Vanhouttei*. Garden hybrid.—*S. sorbifolia*, Linn.—*Sorbaria sorbifolia*.—*S. Tobolskii*, Lodd.—*Sorbaria sorbifolia*.—*S. trifoliata*, Linn.—*Gillenia trifoliata*.—*S. tristis*, Zabel. Hybrid of unknown origin, similar to *S. expansa*, but corymbs and the whitish pink fls. smaller; sepals upright in fr.—*S. Ulmaria*, Linn.—*Filipendula Ulmaria*.—*S. vacciniifolia*, D. Don (S. laxiflora, Lindl.). Shrub, to 2 ft., with arching branches: lvs. long-petioled, ovate, crenately dentate, almost glabrous, ¾-1½ in. long; fls. whitish, in tomentose corymbs, 1-3 in. across. June, July. Himalayas. F.S. 7, p. 190.—*S. vacciniifolia*, Lodd.—*S. gracilis*.—*S. vacciniifolia*, Hort.—*S. canescens*, *S. brumalis*.—*S. venusta*, Hort.—*Filipendula rubra* var. *venusta*.—*S. venustula*, Kunth & Bouché.—*S. vacciniifolia*.

ALFRED REHDER.

SPIRANTHES (name Greek, referring to the twisted spikes). *Orchidaceæ*. LADIES' TRESSES. Terrestrial herbs, few of which have any horticultural value; some of the hardy species are advertised by dealers in native plants and by collectors.

Erect herbs with fleshy or tuberous roots: lvs. mostly at the base or on the lower part of the st.: raceme terminal, twisted; fls. spurless, small or medium-sized; sepals free or more or less united at the top, or united with the petals into a helmet; labellum sessile or clawed, concave, embracing the column and spreading into a

crisped, sometimes lobed or toothed blade; pollinia 2, powdery.—Some 200 species, distributed in all parts of the world except the cold regions, but particularly abundant in the tropics of S. Amer.

A. *Fls. in 3 rows: lvs. persistent at the flowering-time.*

cérnua, Rich. **NODDING LADIES' TRESSES.** Lvs. mostly basal, linear or linear-oblongate: st. 6-25 in. high, usually pubescent above, with 2-6 acuminate bracts: fls. white or yellowish, fragrant, nodding or spreading, in a spike 4-5 in. long; lateral sepals free, the upper arching and connivent with the petals; labellum oblong, rounded at the apex, crisp. Aug.-Oct. Nova Scotia to Minn. and south to Fla. B.M. 1568 (as *Neottia cernua*); 5277. B.R. 823. A.G. 13:467. V. 11:13.

3670. *Spondias cytherea*. (X $\frac{3}{4}$)

Romanzoffiana, Cham. & Schlecht. Lvs. linear to linear-oblongate, 3-8 in. long: st. 6-15 in. high, leafy below: spike 2-4 in. long: fls. white or greenish, zingent, sepals and petals broad at base, connivent into a hood; labellum oblong, broad at the base, contracted below and dilated at the apex, crisp. July, Aug. N. Amer. G.C. II. 16:465; 26:400.

lúcida, Ames. St. 4-10 in. high, glabrous or pubescent, bearing 4-5 lanceolate or oblongate lvs. near the base: fls. small; sepals and petals white, lateral sepals free, narrowly lanceolate, the upper one somewhat united with the petals; labellum quadrate-oblong, yellowish above, not contracted in the middle, wavy-crisp, obtuse or truncate. June-Aug. Maine to Minn. and Va.

AA. *Fls. alternate, appearing in a single spiral row.*

B. *Lvs. present at the flowering-time.*

præcox, Wats. (*S. graminea* var. *Walteri*, Gray). Lvs. linear, 4-12 in. long, grass-like: st. 10-30 in. high, glandular pubescent above, leafy: spike 2-8 in. long: fls. white or yellowish, spreading; lateral sepals free, the upper one connivent with the petal; labellum oblong, contracted above and dilated toward the apex. July, Aug. N. Y. to Fla. and La.

BB. *Lvs. mostly withered at the flowering-time.*

simplex, Gray. Root a solitary oblong tuber: lvs. basal, ovate to oblong, short, absent at the flowering-time: st. very slender, 5-9 in. high: spike about 1 in. long: fls. white; labellum obovate-oblong, eroded and crisp. Aug., Sept. Mass. to Md. A.G. 13:466.

gracilis, Beck. Roots clustered: lvs. basal, obovate to ovate-lanceolate, petioled, mostly dying before the flowering-time: st. 8-18 in. high, bearing a slender, many-fld., 1-sided or twisted spike: fls. white, fragrant; sepals longer than the labellum, the lateral ones free; labellum oblong, dilated in front, crenulate or wavy-crisp, thick and green in the middle. Aug.-Oct. E. N. Amer. A.G. 13:466.

S. colorata, N.E. Br. (*Neottia speciosa*, Jacq.) = *Stenorhynchus*. **HEINRICH HASSELBRING.**

SPIRODÈLA: treated under *Lemna*.

SPIRONÈMA (name means *spiral thread*, alluding to structure of the filaments). *Commelinaceæ*. One species, *S. fragrans*, Lindl., is sometimes listed abroad for hothouse culture, an odd herb from Mex. Sometimes raised under glass for the delicious fragrance and for the transparency of its parts: st. fleshy, 2 ft. and more high: lvs. oblong-lanceolate, sheathing, parallel-veined: fls. white, clustered and nearly sessile in a terminal branched panicle, small, the petals paleaceous and diaphanous, the 3 sepals greenish; stamens 6. B.R. 26:47, where it is written that the plant will be cherished "because its thin and delicate tissue allows the hidden motion of its fluids and the subtle texture of its fructifying organs to be watched with ease and pleasure." It is very little known as a horticultural subject.

SPÓNDIAS (from a Greek word used by Theophrastus). *Anacardiaceæ*. A small genus of tropical trees, allied to the mango (*Mangifera indica*) and the cashew (*Anacardium occidentale*), cultivated for their fruits and often used for hedges because of the readiness with which large branches, when cut and used as posts, take root and grow.

Leaves usually clustered toward the ends of the branchlets, alternate, imparipinnate, with opposite lfts.: fls. polygamous, small, shortly pedicellate, disposed in racemes or panicles; calyx small, deciduous, with 4 or 5 valvate segms.; petals 4 or 5, valvate; stamens 8-10, inserted at the base of the disk; styles 3-5, free at the apex; ovary sessile, 3-5-loculed, with 1 ovule in each locule: fr. a fleshy drupe, with a 1-5-loculed woody endocarp.—Species about 12, several of which are common in the W. Indies, Mex., and elsewhere in Trop. Amer.; one species comes from the Society Isls., another from India.

cytherea, Sonn. (*S. dulcis*, Forst.). **OTAHEITE-APPLE. POMME CYTHERE. CAJÁ MANGA.** VI or EVI in Tahiti. Fig. 3670. Erect, stately tree, with rather stiff branches, up to 60 ft. in height: lvs. 8-12 in. long; lfts. 11-13, oval-oblong, 2 $\frac{1}{4}$ -3 in. long, 1-1 $\frac{1}{4}$ in. broad, acuminate, serrate: panicle 8-12 in. long; fls. whitish: fr. oval or obo-

void, golden yellow, up to 3 in. long, the seed about $1\frac{1}{2}$ in. long, oval, echinate. Society Isls., but widely spread in the tropics.

Mómbin, Linn. (*S. purpurea*, Linn.). SPANISH PLUM. PRUNIER D'ESPAGNE. CIRUELA. Small tree, sometimes spreading, stiff, up to about 25 ft. in height: lvs. 5–8 in. long; lfts. 16–21, oblong-elliptic, $1-1\frac{1}{2}$ in. long, $\frac{5}{16}$ in. broad, usually somewhat asymmetrical, acute or bluntish, subserrate: racemes unbranched, about $\frac{1}{2}$ in. long, few-fl.; the fls. purplish maroon: fr. oblong-obovoid, commonly purplish, about 1 in. long, the seed oblong-elliptical, $\frac{1}{2}-\frac{3}{4}$ in. long, roughened on the surface. Trop. Amer.

lútea, Linn. (*S. Mómbin*, Jacq., not Linn.). HOG-PLUM. MOMBIN. JOBO. CAJÁ. Tall, handsome tree, up to about 60 ft. in height: lvs. 8–12 in. long; lfts. 7–17, ovate-lanceolate or lanceolate, $2\frac{1}{2}-4$ in. long, $1-1\frac{1}{2}$ in. broad, subentire or serrulate: panicle $\frac{1}{2}-1$ ft. long, the fls. yellowish white: fr. ovoid, yellow, $1-1\frac{1}{2}$ in. long, the seed oblong, $\frac{3}{4}-1$ in. long, smoothish. Cosmopolitan in the tropics.

pinnata, Kurz (*S. mangifera*, Willd.). HOG-PLUM. AMRA. Small tree: lvs. 12–16 in. long; lfts. 5–11, ovate-oblong or elliptic-oblong, 4–6 in. long, $1\frac{1}{2}-3$ in. broad, acuminate, entire: panicle 10–14 in. long; fls. whitish: fr. ovoid, yellow-green, $1\frac{1}{2}-2\frac{1}{2}$ in. long, the seed oblong-elliptical, $1\frac{1}{2}-2$ in. long, smoothish. Trop. Asia; according to Hooker, ascending to 5,000 ft. in the Himalayas.

tuberosa, Arruda. IMBÚ. UMBÚ. Low, spreading tree, up to 25 ft. in height, with swollen roots: lvs. 4–6 in. long; lfts. 5–9, oblong-ovate, $1-1\frac{1}{4}$ in. long, $\frac{5}{8}-1$ in. broad, sharply acute to acuminate, cordate at base, entire: panicle 4–6 in. long; fls. whitish: fr. ovoid, light yellow, $1\frac{1}{2}$ in. long, the seed oblong-ovate, slightly flattened, $\frac{1}{2}-\frac{3}{4}$ in. long, smooth. Brazil.

Cultivation and uses.

The Otaheite-apple, *S. cytherea*, is said to have been introduced to Jamaica in 1782, and again in 1792 by the famous Captain Bligh, who brought the bread-fruit from Tahiti to the West Indies. It has not become popular in Cuba, nor is it very extensively grown on the mainland of tropical America. In south Florida it succeeds well, and fine specimens can be seen at Miami and other points. In California it has not yet fruited, so far as known, and seems to be too tender for successful culture in any but the most favored locations. Some of the early travelers who visited Polynesia spoke of it in very high terms, and more recently it has been recommended as worthy of culture by numerous writers. Firminger, however, likens it to a "very bad mango." Probably a great deal depends on the variety. At its best the fruit is the size of a lemon; it is of deep golden yellow color when ripe, aromatic, with a thin but tough skin surrounding the soft, juicy, yellow pulp. The seed is large and oval, furnished with long woody spines over its entire surface. The flavor is sprightly, subacid, aromatic, suggesting the pineapple, but sometimes resinous and disagreeable. It is eaten out of hand, and also used to prepare jams and preserves.

The Spanish plum, *S. Mombin*, is much more common in tropical America, and occurs in a large number of varieties, some of which are of excellent flavor and quality, others rather inferior. In Cuba, where this fruit is called ciruela, the different varieties are distinguished by the addition of such words as roja (red), amarilla (yellow), and the like. In Brazil the species seems to be little known, but in Mexico and Central America it is widely grown. It is successfully cultivated in south Florida, but so far as known has never fruited in California, though it may be possible to grow it successfully in favored locations. The tree, which is much smaller than the Otaheite-apple, is deciduous during a portion of the year, as are the other species.

The fruit is oval, about an inch long, usually purplish red in color, with a bright yellow, very juicy pulp of aromatic, subacid flavor. It is used like the Otaheite-apple.

The hog-plum, *S. lutea*, is one of the least esteemed of the genus. Its fruits are slightly larger than those of *S. Mombin*, but of a rank, pungent flavor which is not especially agreeable. Jumelle says that it makes an excellent refreshing drink. The tree is large and handsome, and is a conspicuous feature of many Cuban landscapes. *S. pinnata*, the hog-plum or amra of India, is scarcely known in America. Indian writers, who do not usually speak highly of it, state that it is used for pickles, preserves, and tarts. Firminger advises using it as a stock for *S. cytherea*.

The imbu of Brazil, *S. tuberosa*, is a little-known species introduced to the United States in 1914 by the Bureau of Plant Industry. Previous to this time it seems to have been unknown outside of its native home, but on the dry lands of interior northeastern Brazil (states of Bahia, Pernambuco, and so on) it is exceedingly abundant and the fruits are highly esteemed by the natives. Its tuberous roots are an adaptation to arid regions. The fruits are the size of large plums, with a pale yellow skin, soft, juicy pulp and a large, nearly smooth seed. The flavor slightly resembles that of a sweet orange, and is very agreeable. An excellent jelly is made from this species, and also a sweet custard called imbuzada, prepared by mixing the strained and sweetened pulp with boiled milk. For eating out of hand it is probably superior to the other species, with the exception of the best varieties of the Spanish plum.

This genus is of very simple culture. All the species are easily propagated by cuttings of large wood, which may be set in permanent locations immediately upon removal from the parent tree. Seeds can easily be grown in flats of light soil, covering them to the depth of an inch. They usually germinate within four to six weeks. Most of the species seem adapted to a variety of soils. They can readily be inarched, but this is not often practised in this country because of the ease with which cuttings can be grown. Improvement of all the species should be carried on by means of selection.

F. W. POPENOE.

SPORE, a reproductive detached cell of a cryptogamous or so-called flowerless plant, not containing an embryo as does a seed. Spores are the reproductive bodies of ferns, mosses, club-mosses, liverworts, fungi, and similar plants. They are of interest to the plant-grower mostly as the means of propagating ferns. For description, see *Ferns and Fungi*; also the articles on *Mildew*, *Rust*, and *Smut*, in Vols. III, V, VI. For propagation by spores, see the discussion under *Ferns*, page 1211, Vol. III.

SPORÓBOLUS (Greek, *spora*, seed, and *ballein*, to cast forth, referring to the grain readily falling from the spikelet). *Gramineæ*. DROPSEED. Spikelets 1-flid., awnless, usually small, in narrow or open panicles.—About 80 species, chiefly of Temp. and Trop. Amer., of little value. *S. cryptandrus*, Gray, a widely distributed annual, is considered a good forage grass; *S. Wrightianus*, Munro, SACATON, of the alkali lands of the S. W. and of Mex., and *S. airoides*, Torr., an allied species, furnish pasture in alkali flats. *S. minutiflorus*, Link, a slender annual with minute spikelets in a delicate panicle, is offered as an ornamental by some seedsmen under the name of *Agrostis minutiflora*. The species are little known horticulturally. A. S. HITCHCOCK.

SPRAGUEA (named for Isaac Sprague, of Cambridge, Mass., botanical artist, collaborator of Asa Gray). *Portulacacææ*. Dwarf half-hardy perennial herbs, well adapted to the rockery: lvs. radical, spatulate, somewhat fleshy; the cauline minute, alternate.

stipules small and scarious: fls. ephemeral, in dense, scorpioid spikes, umbellately clustered on scape-like peduncles; sepals 2, orbiculate-cordate, membranaceous-hyaline, persistent; petals 4; stamens 3; ovary free: caps. membranaceous, rounded-compressed, 2-valved; seeds 8-10, black and shiny.—One, possibly 2 species, W. N. Amer.

umbellata, Torr. Sts. several, simple, erect, 2-12 in. high: radical lvs. spatulate or oblanceolate; the cauline similar but smaller: fls. white, tinged rose, in a dense capitate umbel of nearly sessile spikes; sepals conspicuous; petals oblong-ovate. Late summer. Sierra Nevada, at 3,000-10,000 ft. altitude, from the Yosemite valley to the British boundary, usually in sandy dry soils. B.M. 5143. May be treated as an annual. Var. **caudicifera**, Gray, is a subalpine form in which the caudex-like branches extend for a year or more (the lvs. below dying away) and are at length terminated by scapes an inch or so in length. Desirable for rockwork and edgings.

F. TRACY HUBBARD.†

SPRAYING: *Diseases and Insects*, page 1057, Vol. II.

SPREKËLIA (J. H. von Sprekelsen, of Hamburg, who sent the plants to Linnæus). *Amaryllidaceæ*. **JACOBÆAN LILY**. Half-hardy bulbous plants, generally grown in the greenhouse, often known as amaryllis: lvs. appearing late, strap-shaped-linear: scape hollow, cylindrical, 1-fld.: fl. large, showy; perianth gaping, tube none, upper segm. broadest, 2 lateral lanceolate, 3 lowest deflexed, rolled together inclosing the stamens and style; ovary turbinate, 6-angled, 3-celled: caps. globose-trigonal, 3-valved.—One species, Mex. For cult., see *Amaryllis*; also consult *Hippeastrum*, with which these plants are sometimes confused.

formosissima, Herb. (*Amaryllis formosissima*, Linn.). Bulb globose, 2 in. diam.; tunics brown: lvs. 3-6, contemporary with the fls., linear, green, finally 1-1½ ft. long; peduncle reddish, 6-12 in. long; spathe red-brown, 2 in. long, bifid at the tip; pedicel erect; perianth bright crimson, 3½-4 in. long. April. B.M. 47. G.L. 27:140. G.W. 15, p. 358. Var. **glauca**, Baker (*S. glauca*, Lindl.), has glaucous lvs.: fls. smaller and paler than the type. B.R. 27:16.

F. TRACY HUBBARD.†

SPRING BEAUTY: *Claytonia*.

SPRING-GARDENING. The gardening instinct is at its height in spring. The turn of the season invites it, and the wealth of quick-growing plant-material is great. On the plant-growing side, nothing need be said here that is not already written in other articles in this work, but names of a few plants for spring effects may be suggested.

The spring-gardener will think first of bulbs—crocuses, hyacinths, tulips, squills, snowdrops, fritillies, and others. These are described under their regular alphabetic generic entries, and also under the article *Bulbs* in Vol. I.

If one does not have a greenhouse, many of the annual flowers may be used for early spring bloom if the seeds are started in the window, or, as with pansies, if plants are established in autumn and carried over winter under a protection of leaves or other mulch. Some of the early-blooming hardy annuals are alyssum, candytuft, collinsia, daisy (*Bellis perennis*, perennial but may be treated as an annual after the manner of pansies), pansy, schizopetalon, stocks, violet, Virginian stock, wallflower (annual), pinks as annuals.

The spring-garden will derive its chief satisfaction, however, from the early-blooming perennial herbs, of which there are great numbers of attractive species. A few of the best kinds are here named: *Adonis vernalis*, anemonis, arabis, aubrietia, auricula, clintonia, cowslip (*Primula*), dicentra, forget-me-not, helleborous or Christmas rose (earliest, except perhaps some of the bulbs),

iris, oxalis, *Papaver nudicaule*, pinks, polyanthus and other kinds of primula, pyrethrum, wallflower (perennial), and very many native perennials as epigaea, trillium, erythronium, hepatica, isopyrum, anemone, claytonia, phlox, sanguinaria, caltha.

The wealth of early-blooming trees and shrubs must not be overlooked, nor the beauty of sturdy herbaceous growths pushing from the ground.

A good part of one's success in spring-gardening results from careful preparation the previous autumn, particularly in providing good winter protection for young or partially tender plants that are to be carried over. All should be made ready before winter closes in, so that the first advantage may be taken of the opening of spring.

L. H. B.

SPRUCE: *Picea*. Douglas S.: *Pseudotsuga taxifolia*. Norway S: *P. excelsa*. Sitka S.: *P. sitchensis*. Tideland S.: *P. sitchensis*.

SPURGE: *Euphorbia*. S., Mountain: *Pachysandra procumbens*. S. Nettle: *Jatropha*.

SPURRY (*Spergula sativa*, which see) has long been grown in Germany, France, Holland, and Belgium, where its value as a soil-renovator and as a forage crop was early recognized. It is an annual, and when sown in the spring matures seed in ten to twelve weeks from time of sowing. This plant possesses special value as a renovator for sandy soils. It has long been used by the farmers of Holland to hold in place the shifting sands along the seashore. So well adapted is it to sand that it has been termed "the clover of sandy lands." It is not recommended for the American farmer except where the soil is so poor that other plants fail. In such circumstances it may be used as a cover-crop to plow under. The seed may be sown any time from April to August, but in orchards it would better be sown in July. Sow at the rate of six quarts to the acre. The seed being small, it should be lightly harrowed in upon a well-fitted soil. It is very persistent in the production of seed, and upon fertile soils it will maintain itself for several years unless thorough cultivation is given. Where soils are in fair condition and other crops will grow, it is doubtful whether spurry has any place. Sometimes written spurrey.

L. A. CLINTON.

SQUASH: See the article *Pumpkin and Squash*, page 2859, Vol. V.

SQUAW-BERRY: *Mitchella repens*.

SQUILL: For the garden squill, see *Scilla*; for the medicinal squill, see *Urginea*.

SQUIRREL-CORN: *Dicentra canadensis*.

STACHYS (from an old Greek name applied by Dioscorides to another group of plants, coming from the word for *spike*). *Labiatae*. **WOUNDWORT**. Tall perennial herbs or diffuse annuals, rarely subshrubs or small shrubs, both greenhouse and hardy plants, little known to gardeners.

Leaves very entire or dentate, the floral lvs. similar or reduced to bracts: floral whorls 2- to many-fld., axillary or arranged in terminal spikes: fls. sessile or very short-pedicelled, purplish, scarlet, pale yellow, or white, small or sometimes showy; calyx tubular-campanulate, 5-10-nerved, 5-toothed; corolla-tube cylindrical included or exserted, limb 2-lipped, the posterior often villous outside; stamens 4; nutlets ovoid or oblong.—About 270 species, mainly in the temperate regions but a few in the tropical and colder regions, scattered all over the world. The arrangement followed in the sections and sequence of species is that of Briquet in Engler & Prantl, *Pflanzenfamilien*, IV. 3a:260. Very few of the species are cult., although there are several with showy spikes. They are usually found in moist or even wet places when growing wild. A tuber-bearing species (*S. Sieboldii*) has come into notice as a kitchen-garden plant.

KEY TO SECTIONS.

- A. Outer bracts developed, reaching at least half-way up the calyx, often equalling or even exceeding it.
- B. Annulus or ring at base of corolla absent; corolla-tube mostly exerted; anther-cells parallel. Section I. BETONICA. Species 1-5.
- BB. Annulus or ring at base of corolla oblique and hairy; corolla-tube usually inclosed; anther-cells divergent or divaricate. Section II. ERIOSTOMUM. Species 6-10.
- AA. Outer bracts minute, very much shorter than the calyx. Section III. EUSTACHYS. Species 11-17.

Section I. BETONICA.

- A. Lowest floral-lvs. cordate-ovate.
- B. Corolla more than 1 in. long..... 3. *grandiflora*
- BB. Corolla scarcely $\frac{1}{2}$ in. long..... 1. *densiflora*
- AA. Lowest floral lvs. lanceolate.
- B. Lvs. white beneath..... 5. *discolor*
- BB. Lvs. green or pale beneath.
- c. Calyx $\frac{1}{2}$ in. or more long..... 4. *longifolia*
- cc. Calyx scarcely $\frac{1}{4}$ in. long..... 2. *officinalis*

1. *densiflora*, Benth. (*Betónica incana*, Ait.). Perennial, $1\frac{1}{2}$ ft. high: sts. erect, hirsute: lvs. 2-3 in. long, petioled, ovate-oblong, obtuse, crenate, base cordate, soft-pilose or more or less villous; floral lvs., lowest cordate-ovate, short-petioled: floral whorls approximate in a dense spike, lower whorls remote: calyx campanulate; corolla villous outside, flesh-colored. S. Eu. B.M. 2125.—There are older names referred to this species, but it is not certain that they are truly synonyms; even *Betonica incana* may not belong here.

2. *officinalis*, Franch. (*S. Betónica*, Benth. *Betónica officinalis*, Linn.). BETONY. Fig. 3671. A hardy perennial herb 1-3 ft. high: lower lvs. long-petioled, ovate-oblong, crenate, obtuse, cordate at the base, 3-6 in. long; upper lvs. distant, sessile, oblong-lanceolate, acute: fls. purple, in a dense, terminal spike. July. Eu., Asia Minor. —Rarely found as an escape in this country, and once cult. for use in domestic medicine. Useful for ornament, and now advertised for that purpose. There are white-fl. forms of the species offered in the trade under the names of *S. Betónica alba* and *S. Betónica albiflora* and there is also a large-fl. form with soft rose-colored fls. known as *S. Betónica grandiflora*.

3. *grandiflora*, Benth. (*Betónica rosea*, Hort. *B. spicata*, Hort. *B. grandiflora*, Willd.). A hardy perennial about 1 ft. high: lower lvs. broadly ovate, obtuse-crenate, long-petioled, base broadly heart-shaped; the upper gradually smaller, nearly similar and sessile, the uppermost bract-like: fls. violet, large and showy, the curving tube about 1 in. long and 3 or 4 times surpassing the calyx, in 2-3 distinct whorls of 10-20 fls. each. Asia Minor, etc. B.M. 700. G.M. 53:628. Var. *robusta*, Hort. (*Betónica grandiflora robusta*, Hort. *B. spicata robusta*, Hort.), is said to have tufts of corrugated lvs., to grow 18 in. high and spikes 3 in. long of rosy pink fls. Gn.W. 25:

299. Var. *superba*, Hort. (*Betónica grandiflora superba*, Hort. *B. superba*, Hort.), is said to have showy spikes of intense mauve or a rich shade of purple-violet fls. There is a white variant of this known in the trade as *Betónica superba alba*.

4. *longifolia*, Benth. (*Betónica orientalis*, Linn.). A hardy perennial herb about 1 ft. high, densely villous: lower lvs. petioled, oblong-lanceolate, obtuse, crenate, deeply cordate at the base, 4-6 in. long; the upper lvs. similar in shape but sessile, those of the infl. bract-like: fls. reddish purple to pink, in a cylindrical, somewhat interrupted spike about $\frac{1}{2}$ ft. long. July. Caucasus.—Briquet in Engler & Prantl's Pflanzenfamilien has adopted *macrostachys* as the specific name, basing his name on *Betónica macrostachys*, Wender, but authorities differ as to the identity of Wender's material, hence the Bentham name has been retained.

5. *discolor*, Benth. (*S. nivea*, Benth., not Labill. *Betónica nivea*, Stev.). Perennial, about 1 ft. high, villous: lvs. petiolate, oblong-lanceolate, obtuse, deeply crenate, rugose above, white-lanate beneath; floral lvs., upper lanceolate: floral whorls many-fl., somewhat distinct, few: calyx lanuginose-villous; corolla large, villous, rose, rarely yellowish white. Caucasus.

Section II. ERIOSTOMUM.

- A. Corolla yellow..... 6. *tmolea*
- AA. Corolla purple or pink.
- B. Sts. and lvs. densely white-lanate.
- c. Base of lf. cordate..... 7. *germanica*
- cc. Base of lf. narrowed or sometimes rounded-cordate..... 8. *lanata*
- BB. Sts. lastly soft-pilose-villous: lvs. green above or on both surfaces.
- c. Lvs. green on both surfaces..... 9. *alpina*
- cc. Lvs. green above, canescent-lanate beneath. 10. *sericea*

6. *tmolea*, Boiss. Perennial, about 1 ft. high: sts. ascending, densely sericeous-pannosa: lvs. lanceolate or oblong-lanceolate, obtuse, obscurely dentate, petioled, the radical about 3 in. long; floral lvs. oblong, acuminate: floral whorls densely many-fl., far remote: calyx pedicellate, hirsute, tube campanulate; corolla yellow, tube included. Mt. Tmolus region, Asia Minor.

7. *germanica*, Linn. Perennial, 1-4 ft. high: sts. herbaceous, tall, loosely white-lanate: radical lvs. 2-5 in. long, rather long-petioled; cauline lvs. short-petioled, ovate or ovate-lanceolate, obtuse, base usually cordate, crenate; lower floral lvs. subsessile, somewhat clasping, crenate, white-lanate: floral whorls many-fl., distinct, racemose, upper approximate: calyx lanate inside; corolla pale pink, variegated with white, lanate outside, tube included. Eu., Cent. Asia and N. Afr. B.R. 1289. Var. *Boissieri*, Briq. (*S. cretica*, Sibth. & Smith, not Linn.), has oblong or linear-lanceolate lower lvs., oblong-triangular or short-lanceolate floral lvs. and a rose-colored corolla, the upper lip of which is lanate. S.E. Eu., Asia Minor, and Syria.

3671. *Stachys officinalis*. ($\times \frac{1}{4}$)

8. *lanata*, Jacq. WOOLLY WOUNDWORT. A hardy perennial 1-1½ ft. high, white-woolly throughout: lvs. oblong-elliptical, the upper smaller, the uppermost much shorter and whorled; fls. small, purple, in dense 30- or more-fld. whorls in interrupted spikes. Caucasus to Persia. Gn. 78, p. 543.—Often grown as a bedding plant. Valuable for its very white herbage.

3672. Tuber of *Stachys Sieboldii*. (×¼)

9. *alpina*, Linn. Herbaceous, tall: sts. erect, pilosely somewhat lanate: lvs. petioled, ovate, serrate-crenate, base cordate, both surfaces green or slightly canescent beneath; floral lvs. narrower, gradually smaller: floral whorls all remote, 15-20-fld.: calyx rather pilose, teeth lanceolate-ovate, strongly spined; corolla obscurely purplish or red-brownish, about twice as long as the calyx. Eu.

10. *sericea*, Wall. Herbaceous, tall: st. erect, very pilose: lvs. petioled, ovate or ovate-oblong, rather obtuse, crenate, base cordate, both surfaces villous, green above, pale or hoary beneath, the younger lvs. sericeous-lanate: floral whorls all distant, 10-15-fld.: calyx lanate, teeth ovate-lanceolate, very acute, spined; corolla pink, spotted with purple, hairy, scarcely longer than the calyx. Himalaya region and N. Asia.—There is an older *S. sericea* (of Cavanilles), but its botanical status is unknown. It is a native of Chile.

Section III. EUSTACHYS.

- A. *Species annual*.....17. *corsica*
- AA. *Species perennial*.
- B. *Corolla-tube long-exserted*.....11. *coccinea*
- BB. *Corolla-tube included in the calyx or slightly exserted*.
- C. *Plant with a basal rosette, below which the flowering shoots arise*...16. *citrina*
- CC. *Plant without a basal rosette*.
- D. *Angles of sts. not retrorse-hairy or prickly: annulus inside corolla, oblique, incomplete or even none*.....15. *recta*
- DD. *Angles of sts. retrorse-hairy or prickly, rarely glabrous: annulus inside corolla, pilose, complete*.
- E. *Tubers lacking*.....13. *aspera*
- EE. *Tubers present*.
- F. *Lvs. ovate, deltoid-ovate or ovate-lanceolate: tubers slender, clavate, nodose*...12. *Sieboldii*
- FF. *Lvs. cordate-oblong-lanceolate, very obtuse: tubers cylindrical, uniformly nodose*.....14. *floridana*

Subsection CALOSTACHYDES.

11. *coccinea*, Jacq. One to 2 ft., slender, soft-pubescent: lvs. ovate-lanceolate, cordate at base or somewhat deltoid, obtuse, crenate; fls. scarlet-red, the narrow tube much exceeding the calyx, pedicelled, in an interrupted spike, blooming in succession. W. Texas to Ariz. B.M. 666. P.M. 8:101.—Showy.

Subsection GENUINÆ.

12. *Sieboldii*, Miq. (*S. affinis*, Bunge, not Fresenius. *S. tuberifera*, Naudin). CHOROGI. CHINESE or JAPANESE ARTICHOKE. KNOTROOT. CROSNES DU JAPAN. Fig. 3672. Erect hairy mint-like plant, growing 10-18 in. tall: lvs. ovate to deltoid-ovate to ovate-lanceolate, cordate at base, obtuse-dentate, stalked; fls. small, whitish or light red, in a small spike: tubers (Fig. 3672) 2-3 in. long, slender, nodose, white, produced in great numbers just under the surface of the ground. China, Japan. G.C. III. 3:13.—Sent to France in 1882 from Pekin by Dr. Bretschneider, and about ten years ago intro. into this country. It is cult. for the crisp tubers, which may be eaten either raw or cooked. These tubers soon shrivel and lose their value if exposed to the air. The tubers withstand the winter in Cent. N. Y. without protection, so that a well-established plant takes care of itself and spreads. For history, chemical analyses, etc., see Cornell Bull. No. 37.

13. *aspera*, Michx. Erect, usually strict, 3-4 ft. high, the st. retrorsely hairy on the angles: lvs. oblong-ovate to oblong-lanceolate, mostly acuminate, serrate, petiolate: corolla small, glabrous, pale red or purple, in an interrupted spike. Wet places, Ont. and Minn. to the Gulf. L.B.C. 15:1412.—Has been offered by dealers in native plants.

14. *floridana*, Shuttlew. Slender, erect, 1-2 ft., branching, glabrous: lvs. cordate-oblong-lanceolate, blunt-toothed, stalked; fls. small, light red, in an open interrupted spike: tubers cylindrical, uniformly nodose, 4-6 in. long. Fla.—Has been tested abroad as a food plant, and also at the Cornell Exp. Sta. (see Bull. No. 61), but practically unknown horticulturally. The tubers are as good for eating as those of *S. Sieboldii*.

Subsection RECTÆ.

15. *recta*, Linn. (*S. sylvestris*, Forsk.). Perennial: st. erect or ascending, about 2 ft. high, pilose: lvs. short-petioled, oblong-ovate or lanceolate, obtuse, crenate, 1-1½ in. long, base rounded or narrowed, rugose, hairy; floral lvs. sessile: floral whorls about 10-fld., distant: calyx ovate-campanulate, hairy, teeth ovate, subspinose; corolla yellowish white, throat purplish, glabrous, twice as long as the calyx. S. Eu., Caucasus. Var. *leucoglôssa*, Boiss. (*S. leucoglôssa*, Griseb.). Lvs. narrowly lanceolate, lower serrate, upper entire and linear: calyx somewhat scabrous, teeth as long as the tube. Caucasus.

Subsection INFRAROSULARES.

16. *citrina*, Boiss. & Heldr. Subshrub, gray-canescenscent pannose: lvs. 1-1½ in. long, all basal, long-petioled, elliptical, obtuse, base attenuate, entire or minute, crenulate; floral lvs. narrower: fls. in small terminal heads which are short-ovate, dense, the lower floral whorls often subdistant and interrupted; calyx hirsute, campanulate; corolla sulfur-yellow, hirsute outside, included in the calyx. Greece, E.

3673. *Stachys corsica*. (×¾)

Subsection OLISIÆ.

17. *córsica*, Pers. Fig. 3673. Slender procumbent pilose herb: lvs. about ½ in. long, petioled, ovate, very obtuse, broadly crenate, base rounded or subcordate; floral lvs. smaller: floral whorls 2-4-fld., remote: calyx campanulate, hispid, teeth lanceolate, acute, subspiny; corolla pinkish white, twice as long as the calyx, the tube short-exserted. Medit. region.

Betónica carnea, Hort., is offered in the trade, probably a flesh-colored form of *S. grandiflora*.—*Betónica rubra*, Hort., is also in the trade, probably a red-fl. form of *S. grandiflora*.

F. TRACY HUBBARD.†

STACHYTARPHÊTA (Greek, *dense spike*). *Verbenaceae*. Simple pilose, villous or glabrous herbs or shrubs, suitable for the greenhouse but hardy outside in the extreme southern United States.

Leaves opposite or alternate, dentate, often rugose: spikes terminal, sometimes long and dense, sometimes short or lax: fls. white, blue, purple, or scarlet, solitary in the axils of the bracts, sessile or half sunk in the rachis of the spike; calyx narrow-tubular, 4-5-ribbed, 4-5-toothed; corolla-tube cylindrical, limb spreading, 5-cleft, lobes broad, obtuse or retuse; perfect stamens 2; ovary 2-celled: fr. included in the calyx, oblong-linear.—About 50 species, mostly natives of Trop. and Subtrop. Amer. but one (*S. indica*) is dispersed very broadly in the tropics of Afr. and Asia.

mutabilis, Vahl. A low shrub, scabrous-pubescent: lvs. ovate, dentate, scabrous above, whitish-pubescent beneath: spike long, erect: bracts lanceolate, subulate: calyx 4-dentate, hispid, 4-6 lines long; corolla crimson, fading to rose, $\frac{1}{2}$ – $\frac{3}{4}$ in. across. W. Indies, Mex. to Guiana. B.M. 976. Gt. 3, p. 178.—Cult. in S. Calif.

indica, Vahl (*S. jamaicensis*, Vahl. *S. urticifolia*, Dalz. & Gibs.). Herb, 1-2 ft. high: branches quadrangular: lvs. 1-4 in. long, elliptic, serrate: spikes 3-12 in. long: fls. finally sunk in the thickened rachis, deep blue; calyx 4-toothed, 4-nerved. Trop. Amer.; Asia, probably naturalized. B.M. 1860.

F. TRACY HUBBARD.†

STACHYRUS (Greek, *spike and tail*; in allusion to the form of the inflorescence). *Stachyuraceae*, formerly usually included in *Ternstroemiaceae*. Ornamental woody plants grown for their very early flowers and the handsome foliage.

Deciduous or evergreen shrubs or trees: lvs. alternate, slender-petioled, serrate, with small deciduous stipules: fls. perfect or polygamous, nearly sessile, in pendulous axillary racemes; sepals 4, strongly imbricate; petals 4, imbricate; stamens 8 with slender filaments; ovary superior, incompletely 4-celled; style simple, with 4-lobed stigma: fr. a 4-celled, many-seeded small berry.—Five or possibly 6 species in Japan, China, and the Himalayas.

The species in cultivation are handsome shrubs with spreading branches, with medium-sized bright green, generally ovate to ovate-oblong leaves and pale greenish yellow flowers in long pendulous spikes appearing early in spring before the leaves from the axils along last year's branches. They have proved hardy in sheltered positions as far north as Massachusetts, but the flower-buds which are formed in autumn and remain naked during the winter are killed by the frost, if not protected. They grow well in moderately moist well-drained soil. Propagation is by seeds or usually by softwood cuttings under glass and by layers.

præcox, Sieb. & Zucc. Fig. 3674. Shrub, to 12 ft.: young branchlets reddish brown or chestnut-brown and lustrous: lvs. elliptic-ovate to ovate-lanceolate, acuminate, rounded at the base, serrate with somewhat spreading teeth, glabrous and lustrous beneath or

3674. *Stachyurus præcox*.
($\times \frac{1}{2}$)

slightly pubescent on the veins, 3-6 in. long: racemes 2-3 in. long: fls. campanulate, $\frac{1}{2}$ in. long; style shorter than petals: fr. globose, $\frac{1}{2}$ in. across, greenish yellow with reddish cheek. March; fr. in Sept., Oct. Japan. B.M. 6631. G.C. III. 21:285 (adapted in Fig. 3674). Gn. 75, p. 204. R.H. 1908, p. 87. S.I.F. 1:74.

chinensis, Franch. Shrub, to 15 ft., very similar to the preceding species: young branchlets greenish or dull brown: lvs. ovate to oblong-ovate, long-acuminate, rounded or subcordate at the base, crenately serrate, glabrous, $2\frac{1}{2}$ –5 in. long: racemes 2-3½ in. long: fls. spreading, about $\frac{1}{2}$ in. long; style as long as petals or slightly exserted: fr. globose, $\frac{1}{4}$ in. across. March. Cent. China. Gn. 79, p. 182.

ALFRED REHDER.

STACKHOUSIA (named for John Stackhouse, an English botanist). *Stackhousiaceae*. Small herbs from a perennial herbaceous or woody rhizome, used for ornamental planting in warm climates: lvs. alternate, linear or spatulate, entire, leathery or somewhat fleshy; stipules none or very minute: fls. spicate at the ends of the branches or fascicled along the rachis, rarely racemose, white or yellow, hermaphrodite; calyx small, tube hemispherical, 5-lobed or rarely 5-parted; petals 5, linear or spatulate, claw elongated; stamens 5, inserted on the disk-margin, erect; ovary sessile, free, subglobose, 2-5-lobed or -parted, 2-5-celled: fr. splitting up into 2-5 globose, angular or winged indehiscent berries.—About 20 species, Austral.

monógyna, Labill. (*S. linearifolia*, A. Cunn.). A half-hardy perennial herb, usually simple, about 1½ ft. high, with linear or lanceolate lvs. about 1 in. long: spikes at first dense, then lengthening to 4-6 in.: buds pinkish when young; fls. white. B.R. 1917.—The plant in the Californian trade is apparently not the above species, for it is described as a tall robust shrub with fl.-heads 1-2 in. across, surrounded by imbricated bracts and bright yellow fls. with a purple-streaked keel.

F. W. BARCLAY.

F. TRACY HUBBARD.†

STADMÁNNIA (named for Stadmann, a German botanist); also erroneously spelled *Stadtmannia*. *Sapindaceae*. Branched pustulate trees, apparently very rarely cult.: lvs. alternate, without stipules, abruptly pinnate; lfts. 3-6 pairs, opposite and alternate, oblong, obtuse: panicles axillary, branched: fls. small, pedicelled, polygamo-dioecious; calyx subspherical, 5-toothed; petals none; disk thick, raised and lobed; stamens 8; ovary oblong, 3-celled: berry dry, oblong-spherical, indehiscent.—The only species of this genus that is well known is a tropical tree from the Bourbon Isls., there known as bois de fer or ironwood. This is a large tree with hard, heavy reddish wood, once frequent in the primeval forests of Mauritius but now scarce. It is not known to be in cult. in Amer. Nine other names appear in Index Kewensis, apparently all Brazilian species, but one of them is a bare name and the others were first described in the early 1860's in Linden's catalogue.

oppositifolia, Lam. (*S. Sideroxylon*, DC.). BOIS DE FER. Lvs. alternate, petioled, abruptly pinnate; lfts. 8-12, opposite, oblong, short-stalked, obtuse, coriaceous, entire, oblique at base: panicles dense, cylindrical, 3-4 in. long: fr. hard, globular, nearly 1 in. thick. Mauritius.

S. amabilis, Hort., is offered in the trade, but is not known botanically: it is said to be an imposing decorative plant for greenhouse cult. and to require the same treatment as gardenias.

F. TRACY HUBBARD.†

STAG-HORN FERN: *Platynerium*. S. Sumach: *Rhus*.

STANDARDS OF COLOR MEASUREMENT. There is no universally acknowledged standard of color measurement, nor any international agreement between physicists and artists as to the constituents of such a

standard; consequently, those who wish to abide by some reliable system of color pitch and nomenclature are at liberty to choose between the publications of experts upon this subject without regard for professional or industrial limitations.

A standard of color exclusively useful in horticulture would be an absurdity, inasmuch as a standard would fail to be as far-reaching as the word implies if it did not meet the requirements of all classes of art, science, and industry. There is nothing logical in one normal red named one way for the horticulturist and another named differently for someone else. In the musical profession tone has been standardized by what is known as International Pitch at middle C of the piano-forte. All musical instruments throughout the world are commonly tuned to that pitch; it is an absolute standard. But as yet, the exact pitch of what is called normal red color is not standardized, and as a consequence the whole chromatic scale which by deduction and mathematical measurement should fall into line by the establishment of this one normal hue remains unfixed and is somewhat of a bone of contention between color experts.

A circle divided into the scientifically significant 360°, each one of which represents a distinct hue of the chromatic scale in tangible pigment, is by no means impossible though it is difficult of accomplishment. The writer successfully completed such a scale and finds it remarkably true to the scientific theory of color balance. At the present time, however, there is no mechanical process capable of reproducing such an exact scale with the fidelity it demands.

A diagrammatic representation of the color circle will be found on page 832, Vol. II, of this Cyclopaedia, and the following table (Fig. 3675) indicates exactly the positions occupied in that circle of certain hues contained in the standards of authors mentioned below. A diligent comparison of the figures will demonstrate the lack of agreement among authorities.

Those independent standards of color which are accessible and have proved valuable as practical guides are the following: The extensive and admirable French work entitled, "Répertoire de Couleurs pour aider à la détermination des couleurs des Fleurs, des Feuillages et

des Fruits, publié par la Société Française des Chrysanthémistes et René Oberthur avec la collaboration principale de Henri Dauthenay," (etc.), Librairie Horticole, 84 bis Rue de Grenelle, Paris, 1905. "The Prang Standard of Color," Louis Prang, Boston, 1898, now out of print. The concise and reliable guide entitled "Elementary Color," and the invaluable and popular Bradley Educational Colored Papers, Milton Bradley Co., Springfield, Massachusetts, 1915. The extensive and portable "Ridgway Color Standard and Nomenclature," Robert Ridgway, Washington, D. C., 1912. "The Mathews Chart of Correct Flower Colors" with text, F. Schuyler Mathews, published in the American Florist for August 17, 1895, Chicago. The interesting work entitled "Color Problems," a practical guide for the lay student of color, Emily N. Vanderpoel, Longmans, Green & Co., London and New York, 1902. See also the article on *Color in Flowers*, page 830, Vol. II, of this Cyclopaedia, and for the theoretic basis of spectral color measurement, the article entitled "The World Beyond our Senses," by Carl Snyder, Harper's Magazine for June, 1903.

F. SCHUYLER MATHEWS.

STANGÈRIA (Wm. Stanger, of Natal). *Cycadaceæ*. A warmhouse cycad not very commonly cult.: caudex about a foot high, turnip-shaped: lvs. 3-4, long-petioled, about 2 x 1 ft., pinnate, very glabrous; pinnae opposite and alternate, linear-lanceolate, spinulose-serrulate or subrenate, rarely pinnatifid-lobed: male cone 6 x 1 in.; female cones smaller, 2-3 in. long.—One species, Subtrop. and S. E. Afr. Closely related to *Encephalartos*.

paradoxa, Moore. It is unique among the cycads by reason of the venation of its lfts.: in all the other members of the family the veins of the lf.-segs. are parallel and horizontal; in this one plant they are all free and run directly from the midrib to the margin. This pinnate venation is so extraordinary that the plant looks more like a fern than a cycad, and it was so described before the frs. were known. S. Afr. B.M. 5121. Gt. 63:1598. G.W. 6, p. 109.

WILHELM MILLER.

STANHÔPEA (named for the Earl of Stanhope, president of the Medico-Botanical Society, London). *Orchidaceæ*. Epiphytic orchids easily grown and very interesting, but the fugacious character of their flowers has been unfavorable to their extensive cultivation.

Pseudobulbs clustered on the short rhizome, sheathed with scales and each bearing a single large plaited lf. contracted to a petiole at the base: fls. produced on thick scapes, which bore their way through the material in which they are planted and emerge from the bottom of the basket, large, fragrant, and curiously formed; sepals and petals usually reflexed, subequal or the petals narrower; labellum remarkably transformed, basal part or hypochil boat-shaped or saccate, often with two horns on the upper margin, passing gradually into the mesochil, which consists of a fleshy central part and two lateral horns; the terminal lobe or epichil firmly or movably joined to the mesochil, usually fleshy and keeled but not saccate, base of the labellum continuous with the long-winged column.—About 50 species inhabiting Trop. Amer. from Mex. to Brazil. The fls. expand with a perceptible sound early in the morning.

Stanhopeas enjoy a shady, moist location. A temperature of 60 to 65° F. at night and 70 to 75° during the day should be maintained in winter, with a gradual advance of 10° toward midsummer. They should be grown suspended from the roof in orchid cabins or terracotta baskets with large openings at the bottom, and if drainage is used it should be placed in such a manner that it will not interfere with the exit of the pendulous flower-scapes. Equal parts chopped sphagnum and peat fiber forms a good compost. By severing the rhizome here and there between the old pseudobulbs, new growths will be sent up and thus the stock may be increased. (R. M. Grey.)

A TABLE OF COMPARATIVE COLORS BASED UPON MATHEMATICAL INTERVALS OF 360° OF THE CHROMATIC CIRCLE.

 AA. *Labellum reduced to a saccate pouch*..... 12. *ecornuta*

1. *eburnea*, Lindl. (*S. grandiflora*, Lindl. *S. calceolata*, Hort.). Pseudobulbs conical, $1\frac{1}{2}$ in. long; lvs. leathery, 8–12 in. long; scapes pendulous, with small bracts. 2–3-fld.: fls. 5 in. across, ivory-white; sepals broad; petals narrow; labellum 3 in. long, solid, fleshy, excavated at the base and bearing 2 hooked horns over the mouth, spotted above with reddish purple; column pale green, with broad wings toward the apex. Guiana. B.M. 3359. B.R. 1529. I.H. 14:531 (as var. *specabilis*). L.B.C. 15:1414 (as *Ceratichilus grandiflorus*).

2. *Wardii*, Lodd. Pseudobulbs 2 in. long; lvs. large, broad, and leathery: fl.-st. 9 in. long, bearing 3–9 fls., which are bright yellow to golden orange, spotted with crimson; lateral sepal round-oblong, concave, acute; petals lanceolate, revolute, the cavity in the base of the labellum deep velvety purple. Aug. Mex. and S. B.M. 5289. Gn. 51, p. 28. C.O. 2. Var. *aurea*, Hort. (*S. aurea*, Lodd.). Fls. golden yellow, with 2 dark spots on the hypochil. Fragrant.

3. *oculata*, Lindl. (*S. guttulata*, C. Koch). Fig. 3676. Lvs. ovate, with a blade 1 ft. long; scape 1 ft. long, clothed with scarios pale brown sheaths, 3–6-fld.: fls. 5 in. across, very fragrant, pale yellow, thickly spotted with purple; sepals 3 in. long, reflexed; petals half as large; hypochil narrow, white, spotted with crimson and having 2 large dark brown spots near the base. Mex. B.M. 5300. B.R. 1800. L.B.C. 18:1764 (as *Ceratichilus oculatus*). S.H. 2, p. 435. G.C. III. 19:264; 43:19; 44:115; 52:121. J.F. 3:309–10. C.O. 6.—There are several varieties, differing in color and markings. Fig. 3676 is from an article by Safford on "Sacred Flowers of the Aztecs," named "the serpent-head orchid," in *The Volta Review*.

4. *platyceras*, Reichb. f. Pseudobulbs and lvs. as in *S. Bucephalus* but stouter: scape 2-fld., with ovate

acute bracts half as long as the ovary: fls. 7 in. across, pale yellow, with numerous ring-shaped spots and blotches of purple; sepals triangular-oblong; petals broadly linear, acute; hypochil boat-shaped, $2\frac{1}{2}$ in. long; horns 1 in. long, broad, pointing forward, parallel with the tongue-shaped middle lobe; the hypochil is deep purplish crimson inside, paler and spotted outside, the upper part of the labellum colored like the sepals. Colombia. Gn. 33:534.

5. *Bucephalus*, Lindl. (*S. grandiflora*, Reichb. f.). Pseudobulbs crowded, rugose: lvs. petioled, 9 in. long, pointed: the pendulous raceme bearing 4–6 large,

3676. *Stanhopea oculata*. (X about $\frac{1}{4}$)

tawny orange fls. marked with large crimson spots; sepals and petals reflexed, the former broad; lower part of the labellum curved, boat-shaped, bearing 2 curved horns and a broad fleshy middle lobe; column green and white, spotted with purple. Aug. Mex., Peru. B.M. 5278; 8517. B.R. 31:24.—Fls. very fragrant. Distinguished by its very short ovaries.

6. *insignis*, Frost. Figs. 3677, 3678. Pseudobulbs clustered: lvs. broadly lanceolate: scape 6 in. long, covered with dark brown scales, 2–4-fld.: fls. 5 in. across, dull yellow, spotted with purple; sepals broad, concave; petals narrow, wavy; hypochil globose, almost wholly purple inside, heavily spotted outside, horns 1 in. long, falcate, middle lobe cordate, keeled. July–Oct. Brazil. B.M. 2948, 2949. B.R. 1837. L.B.C. 20:1985. Gng. 2:117 (from which Fig. 3677 is adapted). G.W. 12, p. 283.—Marked by broad wings of column.

7. *Shuttleworthii*, Reichb. f. Pseudobulbs large, conical, sulcate: lvs. broadly oblong, acute: raceme pendulous, loose: sepals, petals, and base of the labellum apricot-color with dark purplish blotches, front part of the labellum yellowish white; hypochil semi-globose; horns flattened, suberect, terminal lobe triangular; column whitish, green along the middle and spotted with purple in the inside. Colombia.

8. *devoniensis*, Lindl. (*S. maculosa*, Knowles & Westc.). Lvs. about 9 in. long: scape pendulous, 2–3-

fld.: fls. 5 in. across, pale brownish, with broad reddish brown blotches; sepals oblong to ovate-oblong, obtuse; petals narrow; hypochil rounded, saccate, purple, horns incurved, middle lobe ovate, channeled, obscurely 3-toothed. Peru. F.S. 10:974. F.C. 3:121.

9. *tigrina*, Batem. Lvs. and pseudobulbs as in the genus: scape short, pendulous, clothed with large, thin brown scales: fls. 6 in. across, waxy and very fragrant; sepals broadly ovate, concave; petals oblong-lanceolate, both dingy yellow mottled toward the base with large blotches of dull purple; hypochil broad, cup-shaped; horns 1 in. long, fleshy, bent forward at right angles; middle lobe rhomboid, with 3 fleshy teeth at the apex; column large, spatulate. Mex. B.M. 4197. B.R. 25:1. G.M. 32:398; 38:149. F. 1845:59. G.C. III. 4:481. C.O. 7.—One of the most striking forms among orchids. Var. *lutescens*, Hort. Brilliant yellow to orange marked with chocolate.

3677. *Stanhopea insignis*.

Guatemala. Var. *superba*, Hort. Van Houtte. Fls. yellow, with the sepals and petals heavily blotched with reddish brown. F.S. 7:713-15. G.M. 51:625. Var. *atrata*, Hort., is advertised. Var. *splendens*, Hort., had deeper-colored fls.

10. *Martiana*, Batem. Lvs. lanceolate: sepals broadly ovate, creamy white with few purple spots on the lower half; petals narrower, blotched with purplish crimson; hypochil saccate, white; lateral horns broad, pointed, middle lobe oblong, obscurely 3-toothed; column subclavate, winged. Mex. F.S. 20:2112, 2113. Gn. 45, p. 470. G. 17:187. Var. *bicolor*, Lindl. Ground-color of the fls. white. B.R. 29:44. G.W. 15, p. 457.

11. *saccata*, Batem. Fls. smaller than those of the other species, greenish yellow, changing to deeper yellow at the bases of the segms., regularly speckled with brown; lateral sepals ovate-oblong, the upper one oblong-lanceolate; petals narrower, oblong, all reflexed; hypochil deeply saccate; horns flat, a little twisted, epichil quadrate. Guatemala. I.H. 8:270 (as *S. radiosa*).

12. *ecornuta*, Lem. Pseudobulbs and lvs. large: scape short, clothed with green bracts, 2-fld.: sepals erect, 2 in. long, ovate, concave, white, petals smaller; labellum reduced to a fleshy sac-like hypochil, $1\frac{1}{2}$ in. long, yellow deepening to orange at the base; column as long as the labellum and of the same color. Cent. Amer. B.M. 4885. F.S. 2:181. G.C. 1850:295.

S. Amesiana, Hort.—*S. Lowii*.—*S. bellarensis*—*S. insignis* × *S. oculata*. R.H. 1896:232.—*S. convoluta*, Rolfe. Sepals and petals ivory-white, the latter with buff tips, the sepals elliptic-oblong, spreading, $2\frac{1}{2}$ –3 in. long, $1\frac{1}{4}$ – $1\frac{1}{2}$ in. wide, the petals connivent, inclosing column, about 2 in. long, $1\frac{1}{4}$ in. wide; lip buff-yellow, with the interior of hypochil orange, over $1\frac{1}{2}$ in. long, 3-lobed; hypochil subglobose; epichil oblong, truncate. Colombia. B.M. 8507.—*S. costaricensis*, Reichb. f. Fls. $4\frac{1}{2}$ –5 in. across, pale yellow, densely purple-dotted; lip with 2 prominent keels on each side; column with small triangular wing at apex. Costa Rica.—*S. elegántula*, Rolfe. Fls. primrose-yellow, with base of petals and hypochil of lip orange, sparsely dotted with brown. Hab. (?)—*S. florida*, Reichb. f. Infl. dense, about 7-fld.: fls. white, the inside of sepals and petals spotted with purple; lip with numerous small purple dots, the hypochil with a large blotch on each side. S. Amer. G.C. II. 16:561, 565; III. 19:265.—*S. graveolens*, Lindl. Fls. ample; sepals greenish white flushed yellowish; petals pale yellow, oblong-ligulate, undulate, shortly acuminate; lip with the hypochil apricot; mesochil white; epichil entire, oval, pointed, white, purple-dotted. Guatemala. G.W. 3, p. 472. C.O. 4.—*S. Haseloviana*, Reichb. f. Fls. 6 in. across; sepals and petals dull gray on back, dull yellowish on surface, covered with annular pale rose spots; lip spotted with dark purple; hypochil quadrate; epichil 3-parted. Peru. B.M. 7452.—*S. inodora*, Lodd. Lateral sepals ovate-oblong; hypochil subcompressed, short, saccate; epichil orbicular-ovate, entire; fls. pale flushed with yellow. Mex. B.R. 31:65. G.M. 57:54. G.W. 7, p. 27.—*S. Langlasseana*, Cogn. Lip erect, rigid, closely pressed against the erect column; petals ascending, pressed

against the column; sepals extended horizontally. Trop. Amer.—*S. Lowii*, Rolfe. Sepals and petals creamy buff, the latter brown-dotted; lip ivory-white, the hypochil branded with dull maroon. Colombia. G.M. 36:352. G.C. III. 14:689. J.H. III. 45:193.—*S. Madouziæna*, Cogn. Fls. fragrant, 5–7 in. across; sepals and petals cream-white, with large spots of carmine-rose, the sepals triangular-oval, obtuse, the petals broadly oblong, obtuse, undulate; lip fleshy, in color like sepals and petals, the inside of hypochil tinged with violet-black; epichil oval, pointed. Colombia. G.C. III. 24:135. C.O. 1.—*S. nigripes*, Rolfe. Sepals and petals yellow, with numerous small purple blotches, the sepals elliptic-oblong, acute, the petals linear-oblong, acute, undulate; lip yellowish white, purple-spotted at base and on epichil, the hypochil with a dark black-purple eye-like spot on each side, the inside the same color, the epichil ovate-orbicular. Origin unknown.—*S. peruviana*, Rolfe. Fls. golden yellow; sepals obtuse, the dorsal oblong, the lateral obliquely and broadly ovate; petals linear-oblong, revolute; lip with the hypochil suffused dark purple on sides; epichil orbicular-ovate, purple-spotted. Peru. B.M. 8417.—*S. Rôndii*, Rolfe. Fls. ivory-white, faintly shaded yellow on lip; sepals elliptic-oblong, acute; petals lanceolate-oblong, acute, lip with the hypochil papillate inside, the epichil triangular, acute. Brazil.—*S. Rodigasiana*, Claes. Fls. about 6 in. across; sepals spreading, oblong-ovate, purple-marbled below, maroon-blotched above; petals triangular-lanceolate, attenuate above, pale green; lip very fleshy, the hypochil suffused with maroon-purple below, the remainder blotched; epichil reticulated, triangular, obtuse, spotted with dull purple. Colombia. B.M. 7702. G.M. 41:492. G.C. III. 24:31.—*S. Rückeri*, Lindl. Resembles *S. Wardii* in color, but paler; hypochil obovate; epichil stained pink. Mex. A.F. 6:631.—*S. stenochila*, F. C. Lehm. & Kränzl. Sepals pure white; petals apricot-colored, with purplish blotches; lip ivory-white at base, middle and interior parts yellow. Colombia.—*S. Wolteriana*, Kränzl.—*S. Martiana* × *S. tigrina*. Fls. dull straw-color or pale orange; sepals obscurely marked with wine-red, the spots on the petals larger. G.C. III. 38:102.

HEINRICH HASSELBRING.

GEORGE V. NASH.†

STANLËYA (named for Edward Stanley, Earl of Derby, 1779–1849). *Cruciferae*. Glaucous glabrous perennial herbs, similar to arabis in habit, suitable for the flower-garden: lvs. undivided or pinnatifid: racemes elongated, strict, many-fld.; fls. yellow; buds elongated, sepals short, spreading; petals narrow, elongated, long-clawed: silique long-stipitate, slender, 4-cornered to rather terete, compressed, valves carinately 1-nerved.—About 10 species, Calif.

pinnata, Brit. (*S. pinnatifida*, Nutt.). Sts. flexuous: lvs. very variable, commonly pinnatifid; segms. lance-oblong or oblanceolate-elliptic, rarely linear, almost entire; terminal segm. larger: fls. deep golden yellow, according to D. M. Andrews. May–July. W. Kans. and Neb. to Texas and S. Calif., in dry clay or alkaline soils.

3678. *Stanhopea insignis*. (× $\frac{1}{2}$)

G.C. III. 29:381.—A hardy perennial herb about 3 ft. high with the general appearance of a cleome and fls. about 1 in. across borne in terminal spikes a foot or more long.

F. TRACY HUBBARD.†

STAPËLIA (J. B. Van Stapel, Dutch physician, died in the early part of the seventeenth century, who wrote on the plants of Theophrastus). *Asclepiadaceæ*. **CARRION FLOWER**. Odd fleshy cactus-like plants usually grown with greenhouse succulents, both for the great oddity of their forms and for the singular and often large showy flowers.

Stems low, leafless, coarsely 4-angled, the angle coarsely dentate, usually more or less covered with tubercles and excrescences: fls. often large, generally fetid and commonly arise from the angles and notches of the sts., apparently in no regularity and are usually grotesquely barred and mottled with dark or dull colors; calyx and corolla 5-parted, corolla-segms. spreading, usually narrow and fleshy, mostly purple or marbled, in some species pale; crown in 2 rows, the outer horizontally spreading, deeply 5-lobed, the lobes entire or shortly 2-3-cleft, the inner of 5 scales adnate to the base of the anthers: fr. of 2 follicles, containing comose seeds.—About 60 species according to N. E. Brown in Dyer, *Flora Capensis*, vol. 4 (1909); Schumann, in Engler & Prantl's *Pflanzenfamilien*, considers that the genus contains 70–80 species; Decaisne, in DeCandolle's *Prodromus*, 8 (1844), describes 89 species, and makes references to several more. S. Afr. chiefly, 3 or 4 in Trop. Afr. Some of the species have fls. several inches across, although the plants themselves are relatively small; in fact, the fls. of *S. gigantea* are a foot across.

Most of the stapelias demand the treatment given to Cape euphorbias and to cacti,—a light, airy, rather dry position during the growing and blooming seasons and a soil made porous with rubble. They are mostly summer and fall bloomers. They should remain dormant in winter. Propagated easily by cuttings. They do best, however, when not grown so dry as cacti are grown. (See under Succulents, p. 2674.) The stapelias are known in cultivation mostly in botanic gardens and in the collections of amateurs. Only a few names occur in the American trade, and one of these (*S. cylindrica*) is an Echinopsis. Several other species are likely to be found in fanciers' collections.

KEY TO THE SPECIES.

- A. Corolla without a distinct raised ring on the disk.
 B. Inner surface of the disk and lobes glabrous and rugose or smooth.
 C. The corolla-lobes extended not more and usually less than 2 in. diam. (except perhaps in No. 9).
 D. Lobes of the corolla nearly smooth, ciliate with long flattened tapering hairs..... 9. bella
 DD. Lobes of the corolla very distinctly ciliate with simple hairs..... 8. similis
 CC. The corolla-lobes extended $2\frac{1}{2}$ –7 in. diam.
 D. Lobes of the corolla ciliate with simple hairs..... 6. Pillansii
 DD. Lobes of the corolla not ciliate..... 7. glabriflora
 BB. Inner surface of the disk or disk and lobes hairy, besides the border of cilia, usually transversely rugose.
 C. Corolla-lobes extended 8–14 in. diam., lobes $2\frac{3}{4}$ –5½ in. long.
 D. Center of corolla shallowly depressed..... 3. gigantea
 DD. Center of corolla cup-shaped, about 1½ in. deep..... 4. nobilis
 CC. Corolla-lobes extended $4\frac{1}{2}$ –6½ in. diam., lobes $1\frac{1}{2}$ –2¾ in. long.
 D. Transverse yellow lines on corolla absent..... 2. grandiflora
 DD. Transverse yellow or whitish lines on corolla present..... 1. hirsuta

- ccc. Corolla-lobes extended 3–4½ in. diam., lobes $1\frac{1}{6}$ –1¾ in. long... 1. hirsuta var.
 cccc. Corolla-lobes extended 2–3 in. diam., lobes 1–1½ in. long.
 D. Disk of corolla shortly and usually thinly pilose or pubescent with erect hairs..... 11. maculosoides
 DD. Disk of corolla thickly or densely covered with fine long hairs... 5. tsomoensis
 AA. Corolla with a distinct raised ring or cushion on the disk.
 B. Inner lobes of the crown sometimes slightly humped at the base or connected to the outer row, but not produced into a distinct dorsal horn (see also No. 12 in which the outer horn is sometimes not more than ¼ line long)..... 13. namaquensis
 BB. Inner lobes of crown distinctly 2-horned.
 C. Annulus or ring ½–2 lines high, erect, very obtuse or rounded at the top, not cushion-like nor with a spreading or recurved margin.
 D. The corolla pale yellowish or light yellow with spots and transverse lines on the basal part of the lobes dark purple-brown to dull purple, and their tips often entirely purple-brown, or in the variety entirely dark purple-brown with inconspicuous transverse yellow lines..... 10. mutabilis
 DD. The corolla pale yellow, sprinkled all over with dots or small spots of purple-brown, lobes 5–10 lines long, not ciliate..... 12 pulchella
 CC. Annulus or ring very prominent, with an acute edge to the horizontally spreading or recurved margin..... 14. variegata

1. *hirsuta*, Linn. Sts. erect, 5–8, occasionally 12 in. high, softly puberulous, green: fls. 1–3 together, near the base of young sts.; corolla 4–5 in. diam., basal half of lobes cream-color, more or less tinted with purplish on the disk, upper half very dark purple-brown, marked with transverse cream-colored or yellowish and purple-brown lines, white-hairy. S. Afr. Var. *unguipetala*, N. E. Br. (*S. unguipetala*, N. E. Br.). Corolla $3\frac{1}{2}$ –4½ in. diam., disk with the center and 5 bands radiating to the sinuses, pale greenish ochre, margins of the upper half of the lobes much revolute, tips up-curved. S. Afr. G.C. II. 7:335; III. 44: 169.

2. *grandiflora*, Mass. Fig. 3679. Sts 6–12 in. high, gray-velvety-pubescent, with very compressed angles: fls. 1–3 together, near the base of the sts.; corolla 5–6 in. diam., velvety-pubescent, inner face dark purple-brown, lobes ciliate, darkest toward the tip, upper half rugose and transversely rugose, without markings, basal half white or pale-purple-haired. S. Afr. G.L. 27:67. R.B. 40, p. 186. R.H. 1858, p. 154.

3. *gigantea*, N. E. Br. Sts. erect, branching from a short decumbent base, 4–8 in. high, pubescent, light

3679. *Stapelia grandiflora*. ($\times \frac{1}{2}$)

dull green, angles much compressed: fls. 1 or 2 together, near the base or toward the middle of the sts.; corolla 11-16 in. diam., disk-like, center shallowly depressed, inner surface transversely rugulose, pale-purple-hairy, light ochre-yellow, everywhere marked with transverse crimson lines, lobes 4-6½ in. long. Trop. and S. Afr. B.M. 7968. G.C. II. 7:693; III. 4:729. G.F. 8:515.—"The requirements of *S. gigantea*," Watson writes, "are somewhat exceptional. It thrives only when grown in a hot, moist stove from April till September, when the growth matures and the flower-buds show. It should then be hung up or placed upon a shelf near the roof-glass in a sunny dry position in the stove."

4. *nobilis*, N. E. Br. Sts. erect, decumbent and branching at base, 3-5 in. high, sides concave, softly pubescent, green: fls. 1-5 together, near the base or middle of the young branches; corolla very large, with a distinct campanulate tube about 1½ in. deep, lobes 2¾-4 in. long, light reddish purple on the back, inner face transversely rugulose, light ochre-yellow everywhere marked with irregular transverse crimson lines. S. Afr. B.M. 7771.

5. *tsomoënsis*, N. E. Br. Sts. 4-6 in. high, angles compressed and somewhat repand-dentate, opaque green: fls. 4-9 together, near the base of the young sts.; corolla 2½-3 in. diam., outside glabrous, light green, inside with a few raised transverse ridges on the upper half of the lobes, entirely dull smoky purple, darker at the tips of the lobes. S. Afr.

6. *Pillánsii*, N. E. Br. Sts. rather crowded, 4-7 in. high, sides concave, angles not much compressed, velvety-pubescent, green: fls. 2-5 together, near the base of the sts., 4-5½ in. diam., inner surface transversely rugose and glabrous, purple-brown without markings, shining, densely ciliate with soft light purple, simple hairs. S. Afr. G.C. III. 35:242; 44:187.

7. *glabriflora*, N. E. Br. (*S. glabrifolia*, Bailey, error. *S. grandiflora* var. *minor*, Hort.). Sts. erect, 4-9 in. high, puberulous, green, angles much compressed: fls. 1-2 together at the middle or lower part of young sts.; corolla 3-4½ in. diam., velvety on the back, transversely rugose and quite glabrous on the inner face, not ciliate, dull reddish purple, darker at tips of lobes, whole surface transversely marked with very narrow linear, irregular yellowish white lines. S. Afr. G.C. II. 6:809; III. 44:186.

8. *similis*, N. E. Br. Sts. erect, 3-6 in. high, 4-6 angled, minutely puberulent, dull purple or gray-green, purple-spotted; angles somewhat denticulate: fls. 3-6, borne at the base of the st.; corolla rotate, less than 1 in. across, outside minutely puberulent, inside transverse rugose, glabrous, not ciliate, dark purple, lobes ovate, acute. S. Afr.

9. *bélla*, Berger. Sts. erect, branching at or above the base, 5-7 in. high, sides concave, minutely pubescent, dull green: fls. 3-4 together at the base of the young sts.; corolla 1¾-2 in. diam., glabrous inside and out, inner face deep purplish red, browner toward the tips of the lobes, paler at the center, the small tube whitish, without markings, ciliate on the lobes. A hybrid of European raising. G.C. III. 31:138; 44:168.

10. *mutábilis*, Jacq. Sts. 3-18 in. high, acutely 4-angled, with rather stout conical, spreading teeth, glabrous, green, sometimes tinged with purple, slightly glaucous: fls. 1-3 together, from near the base of the younger or higher up on the older sts.; corolla with lobes very much recurved and then about 1½ in. diam., glabrous on both surfaces, inner face slightly rugose to nearly smooth, the upper third of the lobes light or dark purple-brown, the remainder pale yellowish or greenish yellow, covered with transversely elongate spots or thick or narrow, irregular transverse purple-brown lines. S. Afr. Var. *discolor*, N. E. Br. (*S. dis-*

color, Tod.). Corolla dark purple-brown with inconspicuous yellowish transverse lines on parts of the disk; annulus yellow with irregular purple lines. S. Afr.

11. *maculosoides*, N. E. Br.; also erroneously spelled *masculosoides*. Sts. erect, about 3 in. high, obtusely 4-angled, glabrous: corolla about 2¾ in. diam., glabrous outside, center dark violet-purple, lobes 12-13 lines long, slightly rugose, marked with dark violet-purple transverse lines and spots on a light yellowish ground on the central part and with dark violet-purple margins and tips, ciliate. Probably a European hybrid.

12. *pulchélla*, Mass. Sts. 2-4 in. high, erect or decumbent at base, obtusely 4-angled, glabrous, green: fls. usually 3 or more together, near the base of the sts.; corolla 1¼-2¼ in. diam., smooth on the back, minutely tuberculate-rugulose and glabrous inside, not ciliate, sulfur-yellow, covered with numerous purple-brown dots, lobes sometimes narrowly edged with purple-brown. S. Afr.

13. *namaquensis*, N. E. Br. Sts. procumbent or decumbent, 1½-3¼ in. high, obtusely 4-angled, with very stout, acute, conical spreading teeth, glabrous, green, marked with irregular purple stripes: fls. 1-4 together, near the base or middle of the young sts.; corolla 3-4 in. diam., back smooth and glabrous, inner surface very rugose with transverse papillate ridges on the lobes which are 1-1¼ in. long, yellow, dotted with purple-brown. S. Afr. Var. *ciliolata*, N. E. Br. (*S. ciliolata*, Ruest, not Tod.). Corolla shortly ciliate, with simple or subclavate white or white and dark purple hairs mixed, spotting variable.

14. *variegata*, Linn. (*S. normalis*, Jacq.). Plant glabrous: sts. erect from a decumbent base, 2-6 in. high, very obtusely 4-angled, green, often mottled all over or tinted with purple at the tips: fls. 1-5 together, at base of young sts.; corolla 2-3 in. diam., lobes smooth and green outside, inner surface rugose with crowded irregular transverse ridges on the lobes, pale greenish yellow, with dark purple-brown spots. S. Afr. B.M. 26. R.H. 1857, p. 43. Var. *atrata*, N. E. Br. (*S. atrata*, Tod.). Corolla-lobes deltoid-acuminate, ground-color dark purple-brown. Var. *atropurpurea*, N. E. Br. (*S. atropurpurea*, Salm-Dyck). Corolla-lobes ovate; ground-color blackish purple. Var. *clypeata*, N. E. Br. (*S. Bufonis*, Sims). Corolla 2½-3 in. diam. spotted all over, with or without a few slender transverse lines at the base of the lobes. B.M. 1676. Var. *Curtisii*, N. E. Br. (*S. Curtisii*, Schult.). Outer lobes of crown very slightly notched; ground-color of corolla light yellow or rather bright sulfur-yellow. Var. *mixta*, N. E. Br. (*S. mixta*, Mass.). Corolla 2½-3¾ in. diam., light-colored; lobes with numerous rounded spots, those of the basal half connected by slender transverse purple-brown lines. Var. *trisulca*, N. E. Br. (*S. trisulca*, Donn.). Corolla in mature bud flat-topped, without a point, when expanded flat on the back of the disk.

S. albicans, Sprenger. A hybrid with partly whitish sts.: corolla 2-2½ in. diam., dark purple-brown at the tips of the lobes, otherwise yellow with purple-brown transverse lines.—*S. Astéria*, Mass. STARFISH FLOWER. Dwarf: sts. mostly curved: corolla 4-5 in. diam., with spreading star-like segms., violet-purple with transverse, yellowish bars. B.M. 536. L.B.C. 5:453.—*S. atrosanguinea*, N. E. Br., with intense blackish crimson fls. is in reality a *Caralluma*, *C. atrosanguinea*, N. E. Br.—*S. cantabrigiensis*, Berger (*S. hybrida cantabrigiensis*). Hybrid: corolla 6½-8 lines across, broadly campanulate, greenish, suffused with red outside, brown-red inside, rather densely covered with red-brown hairs.—*S. Caroli-Schmidtii* is offered in the German trade.—*S. cylindrica*, Hort.=*Echinopsis cereiformis*.—*S. divergens*, N. E. Br. Hybrid: corolla about 2 in. diam., inner surface slightly rugulose, light yellow, irregularly marked with brownish crimson lines.—*S. Engleriana*, Schlecht. Fls. solitary; corolla dark brown, lobes triangular. S. Afr.—*S. Flückii*, Berger & Schlecht., is offered in the German trade. S. E. Afr.—*S. fétida*, Hort., is an American trade name which might apply to any species in the genus.—*S. Hanburyana*, Berger & Ruest. Hybrid: corolla about 2½ in. diam., inner surface somewhat rugose, lobes pale greenish yellow, evenly marked all over with small transverse, purple-brown spots or short lines, narrowly edged with the same color.—*S. Leendertzii*, N. E. Br. St. erect from a decumbent base, 3-5 in. high: corolla large, campanulate, tube 2-2½ in. long, 1¾-2¼ in. across, dull fuscous-purple. Trans-

vaal. B.M. 8561.—*S. longipedicellata*, N. E. Br. (*S. kwebensis* var. *longipedicellata*, Berger). Sts. clustered, erect, 4-6 in. high; corolla $1\frac{1}{2}$ - $1\frac{3}{4}$ in. across, tube short, purplish, lobes blackish. Trop. Afr.—*S. luxurians*, Dammann. Hybrid: corolla about 3 in. diam., not ciliate, entirely dark purple-brown.—*S. magna*, Berger. Hybrid: corolla dark brown, with yellowish markings, with violet-red curled hairs.—*S. Planchii*, Hort. Sts. stout and erect: corolla about 5 in. diam., hairy, brown barred with yellow, lobes margined with brown-purple. S. Afr. B.M. 5692. F.S. 19:2012.—*S. portia-laurinae* is offered in the German trade.—*S. pitida*, Berger. Hybrid: sts. $1\frac{1}{2}$ -2 in. high; corolla-lobes yellowish with large purple-brown spots and a red line along the margin, not ciliate.—*S. rectiflora*, Ruest. Hybrid: corolla about 2 in. diam. with a shallow cup-like disk and spreading sulfur-yellow lobes, with rounded and not very numerous purple-brown spots often confluent in longitudinal rows.—*S. Schinzii*, Berger & Schlecht., is offered in the German trade. S. E. Afr.

F. TRACY HUBBARD.†

STAPHYLÈA (Greek, *staphyle*, cluster, referring to the inflorescence). *Staphyleaceæ*, formerly referred to the *Celastraceæ*. **BLADDER-NUT.** Ornamental woody plants chiefly grown for their attractive white flowers and for their handsome foliage, and also for the inflated pod-like fruit.

Deciduous shrubs or small trees, with smooth striped bark: lvs. opposite, 3-7-foliolate; lfts. serrulate, like the lvs. stipulate: fls. perfect, 5-merous in terminal panicles; sepals and petals 5, of about the same length, upright; stamens 5; pistils 2-3, usually connate below: fr. a 2-3-lobed, inflated, membranous caps., with 1 or few subglobose rather large, bony seeds in each cell.—Eleven species in the temperate regions of the northern hemisphere.

The bladder-nuts are upright shrubs or small trees with handsome bright or light green foliage and ornamental white or pinkish flowers in nodding clusters followed by bladder-like fruits conspicuous by their size and pale green color. The species are all inhabitants of temperate regions, and *S. trifolia*, *S. Bumalda* and *S. pinnata* are hardy North, while *S. colchica*, *S. Bolanderi*, and *S. holocarpa* are hardy at least as far north as Massachusetts; *S. emodi* is more tender and seems not to be in cultivation in this country. They are all desirable shrubs and flower in early summer after the leaves except *S. holocarpa* which blooms in spring before or with the leaves. They are well adapted for shrubberies, but all except *S. Bumalda* are liable to become bare and unsightly at the base and are therefore not to be recommended for single specimens. *S. holocarpa* is perhaps the most beautiful species in bloom; also *S. elegans*, *S. colchica*, and *S. Bumalda* have very handsome flowers. *S. colchica* blooms at an early age and is sometimes forced, but *S. holocarpa* is probably even better adapted for that purpose. *Staphyleas* grow well in almost any kind of soil and position, but do best in a somewhat moist rich earth and partly shaded situation. They are always interesting although not showy. Propagation is by seeds, layers, and suckers. Greenwood cuttings from forced plants root readily.

A. Lvs. 5-7-foliolate, only occasionally 3-foliolate: panicles stalked.

B. Panicle raceme-like, oblong, pendulous: fl.-buds subglobose.

pinnata, Linn. Upright shrub, attaining 15 ft., sometimes tree-like: lfts. 5-7, ovate-oblong, long-acuminate, sharply and finely serrate, glabrous and glaucescent beneath, 2-3 in. long; panicles 2-5 in. long, on peduncles about 2 in. long; sepals oval, whitish, greenish at the base, reddish at the apex, about as long as the oblong petals: caps. 2-3-lobed, much inflated, subglobose, about 1 in. long. May, June. Eu. to W. Asia. Gn. 34, p. 280. G. 4:473. H.W. 3, p. 52.

BB. Panicle broad, upright or nodding: fl.-buds obovate-oblong.

colchica, Stev. (*Hoibrénkia formosa*, Hort.). Upright shrub, attaining 12 ft.: lfts. usually 5, sometimes 3, oblong-ovate, acuminate, sharply serrate, glabrous and pale green beneath, 2-3 in. long; panicle 2-3 in. long

and almost as broad, on a peduncle 2-3 in. long; sepals narrow-oblong, spreading, yellowish white; petals linear-spatulate, white: caps. obovate, much inflated, $1\frac{1}{2}$ -2 in. long. May, June. Caucasus. B.M. 7383. R.H. 1870, p. 257. J.H. III. 34:183. F. 1879, p. 123. G.C. II. 11:117; III. 2:713; 10:161. A.G. 18:423. Gt. 24:837; 37, p. 501. Gn. 34, p. 281; 76, p. 171. G. 2:323; 26:115 (forced plant); 27:170. G.M. 55:215. Gn.W. 5:49; 23:57. F.E. 23:585.—Var. *Coulombièri*, Zabel (*S. Coulombièri*, André). Of more vigorous growth, with denser foliage: lvs. larger and longer-stalked; lfts. long-acuminate: stamens glabrous: caps. 2-4 in. long, spreading at the apex.

AA. Lvs. 3-foliolate.

B. Middle lft. short-stalked, stalk $\frac{1}{2}$ in. or less long: panicle sessile.

Bumálda, DC. Shrub, 6 ft. high, with upright and spreading slender branches: lfts. broadly oval to ovate, shortly acuminate, crenately serrate, with awned teeth, light green, almost glabrous, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long; fls. about $\frac{1}{2}$ in. long, in loose, erect panicles 2-3 in. long; sepals yellowish white, little shorter than the white petals: caps. usually 2-lobed, somewhat compressed, $\frac{3}{4}$ -1 in. long. June. Japan. S.Z. 1:95.

BB. Middle lft. slender-stalked: panicles stalked.

C. Fls. after the lvs.

trifolia, Linn. **AMERICAN BLADDER-NUT.** Fig. 3680. Upright shrub, with rather stout branches, 6-15 ft. high:

3680. *Staphylea trifolia*. ($\times \frac{1}{4}$)

lfts. oval to ovate, acuminate, finely and sharply serrate, slightly pubescent beneath or almost glabrous, $1\frac{1}{2}$ -3 in. long; fls. about $\frac{1}{2}$ in. long, in nodding panicles or umbel-like racemes; sepals greenish white, petals white: caps. much inflated, usually 3-lobed, $1\frac{1}{2}$ -2 in. long. April, May. Que. to Ont. and Minn., south to S. C. and Mo. Gt. 37, p. 529. Var. *pauciflora*, Zabel. Low and suckering: lfts. smaller, broader, glabrous at length: fls. in short, 3-8-fld. racemes: fr. often 2-lobed, $1\frac{1}{2}$ - $1\frac{1}{2}$ in. long.

Bölanderi, Gray. Fig. 3681. Shrub: lfts. broadly oval or almost orbicular, acute, sharply serrulate, glabrous, 2-3 in. long; fls. in many-fld. nodding panicles; stamens and styles exserted: fr. 3-lobed, much inflated, 2- $2\frac{1}{2}$ in. long. Calif., in the Sierra Nevada region. G.F. 2:545 (adapted in Fig. 3681). R.H. 1910, p. 305.—A rare shrub, probably not regularly in cult.

cc. Fls. before the lvs.

holocarpa, Hemsl. Shrub or small tree, to 25 ft.: lfts. 3, oval to ovate-oblong, short-acuminate, serrulate, pale and reticulate and glabrous or nearly so beneath, 2-4 in. long; fls. white or pinkish, nearly $\frac{1}{2}$ in. long, in pendulous slender-stalked panicles 1-4 in. long, axillary on last year's branchlets: fr. pear-shaped or ellipsoid, abruptly acuminate or sometimes lobed at the apex, $1\frac{1}{2}$ -2 in. long; seeds light grayish brown, lustrous, $\frac{1}{4}$ in. long. Cent. China.—Very floriferous and handsome. The name has been misspelled *S. lobocarpa*. Var. *rosea*, Rehd. & Wilson. Lfts. whitish tomentose beneath while young, later villous along the midrib beneath only: fls. pink, $\frac{1}{2}$ in. long. Cent. China.

S. elegans, Zabel. Intermediate between and supposed to be a hybrid of *S. pinnata* and *S. colchica*: lfts. usually 5: panicles very

large and nodding. A very free-flowering variety with pinkish tinged fls. is var. *Hessei*, Zabel.—*S. emodi*, Wall. Shrub or small tree: lfts. 3, oval to oblong, 2-6 in. long; stalk of terminal lft. about 1 in. long; fls. in peduncled, pendulous, raceme-like panicles: fr. 2-3 in. long. Himalayas.

ALFRED REHDER.

STAR-APPLE: *Chrysophyllum*. **Starfish Flower:** *Stapelia*. **Asterias.** S. Flower: *Aster*, *Trientalis*, *Tritele* a and other plants. **S. Grass:** *Chloris truncata*. **Star of Bethlehem:** *Ornithogalum umbellatum*. **S. Thistle:** *Centaurea*. **S. Tulip:** *Calochortus*. **Starwort:** *Aster*.

STÁTICE (Greek name meaning *astringent*, given by Pliny to some herb). Syn., *Armeria*, Auth., not Linn. (see Vol. I, p. 395). *Plumbaginaceæ*. **SEA-PINK.** **THRIFT.** Interesting hardy border perennials, biennials, and annuals useful for both the many-flowered bright inflorescence and the stiff more or less evergreen foliage; flowers blue, lilac, white, yellow.

The genus *Statice* as defined by Linnæus, "Genera Plantarum," ed. 5 (1754), is based on *Statice*, Tourn., and *Limonium*, Tourn.: *Statice* of Tournefort is the *Armeria* of later authors, while *Limonium* of Tournefort is the *Statice* of later authors and of Linnæus in part. Consequently, in dividing the Linnæan genus we

3681. *Staphylea Bolanderi*. (×½)

must retain the name for that part of it which represents the origin of the name, which is exactly what Miller did in "The Gardener's Dictionary," ed. 8 (1768), retaining the name *Statice* for those species with a globular head and reestablishing *Limonium* as the generic name of those species with an open inflorescence. This treatment is accepted by most recent authorities although it is not followed by Pax in Engler & Prantl's "Natürlichen Pflanzenfamilien."

Although the individual flowers are small, some of the sea-pinks are very showy because of the great numbers of clustered blossoms and the brilliant colors. The flowers are often scarious and may be treated as everlasting. The evergreen or semi-evergreen character of the tufted foliage also adds much interest. The plants are easy to grow, remaining for some years when well established, rooting deep. Usually grown from seed.

KEY TO THE SPECIES OF STATICE.

- A. Calyx produced into a spur.
 - B. Bracts between the fls. small, scarcely exceeding the fruiting pedicels..... 1. *fasciculata*
 - BB. Bracts between the fls. about equaling the calices in the interior of heads.
 - C. Lvs. linear 2. *Welwitschii*
 - CC. Lvs. oblong-ovate 3. *mauritanica*
- AA. Calyx not produced into a spur.
 - B. Tube of calyx usually pilose all over.
 - C. Inner lvs. of rosette not like the outer 7. *junceæ*
 - CC. Inner lvs. of rosette like the outer.
 - D. Pedicel as long as the calyx-tube. 4. *Armeria*
 - DD. Pedicel about half as long as the calyx-tube.
 - E. Apex of lvs. rather acute..... 5. *labradorica*
 - EE. Apex of lvs. obtuse 6. *sibirica*
 - BB. Tube of calyx glabrous or pilose only on the ridges.
 - C. Spikelets stipitate inside the involucre 15. *leucocephala*
 - CC. Spikelets sessile inside the involucre.
 - D. Exterior lvs. of the rosette differing from the others.
 - E. Involucre pale brown 13. *majellensis*
 - EE. Involucre white, showy 14. *undulata*
 - DD. Exterior lvs. of the rosette the same as the others.
 - E. Lvs. oblong-lanceolate or broader 12. *pseudo-*
 - EE. Lvs. linear-lanceolate or narrower. [*armeria*]
 - F. The lvs. 3-cornered in cross-section 8. *cæspitosa*
 - FF. The lvs. flat.
 - G. Blades 3-7-nerved 11. *plantaginea*
 - GG. Blades 1-, occasionally obscurely 3-nerved in No. 9.
 - H. Involucre pale brown. 9. *montana*
 - HH. Involucre green 10. *purpurea*

For descriptions of the following species and varieties of *Statice*, see *Armeria* (Vol. I).

3. *S. mauritanica*, Hubb. (*Armeria mauritanica*, Wallr. A. *cephalotes*, Hook., not Schousb.).

4. *S. Armeria*, Linn. (*Armeria maritima*, Willd. A. *vulgaris*, Willd.). Var. *alba*, Hubb. (*Armeria vulgaris* var. *alba*, Hort.) Var. *grandiflora*, Hubb. (*Armeria vulgaris* var. *grandiflora*, Hort. ex Bailey). Var. *Lauchæana*, Hubb. (*Armeria vulgaris* var. *Lauchæana*, Bailey. A. *Lauchæana*, Hort.). Var. *purpurea*, Hubb. (*Armeria vulgaris* var. *purpurea*, Hort. ex Bailey). Possibly a synonym of *S. purpurea*, so considered by some authors. Var. *rubra*, Hubb. (*Armeria vulgaris* var. *rubra*, Hort. ex Bailey). Var. *splendens*, Hubb. (*Armeria vulgaris* var. *splendens*, Hort. ex Bailey). Possibly the same as var. *Lauchæana*.

6. *S. sibirica*, Ledeb. (*Armeria sibirica*, Turcz.).

7. *S. junceæ*, Hubb. (*Armeria junceæ*, Girard).

9. *S. montana*, Mill. (*Armeria alpina*, Willd.).

10. *S. purpurea*, Koch (*Armeria purpurea*, Koch).

11. *S. plantaginea*, All. (*Armeria plantaginea*, Willd.). Var. *leucantha*, Hubb. (*Armeria plantaginea* var. *leucantha*, Boiss.).

12. *S. pseudoarmeria*, Murr. (*Armeria latifolia*, Willd., not *S. latifolia*, Smith. A. *cephalotes*, Link &

Hoffm., not Hook.). The name *pseudoarmeria* has also been used for two other species, but the Murray definition applies to this species and his is the oldest use of the name.

14. *S. undulata*, Bory & Chaub. (*Armèria undulata*, Boiss. *A. argyrocéphala*, Wallr.).

The following species and varieties, all of which are in the trade, are not included under *Armeria* in Vol. I. According to Otto Kuntze and others there is but one species of *Statice*, *S. Armeria*, all the others being variants of this polymorphic species. The great confusion in synonymy seems to uphold this view to some extent and it is certainly questionable whether the varieties of *S. Armeria*, *S. plantaginea*, and *S. pseudoarmeria* are all of them distinct.

1. *S. fasciculata*, Vent. (*Armèria fasciculata*, Willd.). Glabrous, subshrubby at base: lvs. glaucescent, linear, canaliculate, thick, stiff and pointed: involucre lvs. in several rows, fuscous, triangular-ovate, the inner ones white-margined: fls. pale pink. Spain, Corsica, and Sardinia.—The lvs. are somewhat yucca-like.

2. *S. Wéiwitschii*, Hubb. (*Armèria Wéiwitschii*, Boiss.). Base subshrubby, glabrous: lvs. glaucescent, linear, somewhat channeled, obscurely 1-nerved beneath, acuminate; involucre lvs. fuscous, white-margined, lowest triangular. Portugal.

4. *S. Armèria* var. *variegata*, Hubb. (*Armèria maritima* var. *variegata*, Hort.), forms prostrate masses of bright golden foliage and has heads of rose fls.

5. *S. labradorica*, Hubb. & Blake (*Armèria labradorica*, Wallr.). Lvs. glabrous, linear, flat, 1-nerved, rather acute: scapes 1 or 2, low, pubescent; involucre scales herbaceous on the back, the outer ovate, the inner broadly membranaceous-margined. Labrador and Greenland.

8. *S. cæspitosa*, Ort., not Poir. (*Armèria cæspitosa*, Boiss. *A. bella*, Hort., not Alboff. *A. cæspitosa* var. *vera*, Hort.). Forming dense cushions: lvs. very short, narrowly linear, triquetrous, short, white-mucronate: scape pubescent; involucre lvs. brownish: fls. in small heads, bluish-pink or pale lilac. Mountains of Spain and Portugal. B.M. 7596.—*S. cæspitosa*, Poir., equals *S. Armeria*; probably at least some of the material grown as *S. cæspitosa* is that species.

9. *S. montana* var. *alba*, Hubb. (*Armèria alpina* var. *alba*, Hort.), is a white-fl. form.

11. *S. plantaginea* var. *alba*, Hubb. (*Armèria plantaginea* var. *alba*, Hort.), has large heads of white fls., 1 ft. high. Var. *gigantea*, Hubb. (*Armèria plantaginea* var. *gigantea*, Hort.), grows 3 ft. high, has rigid sts., and large heads of glistening pink fls. Var. *grandiflora*, Hubb. (*Armèria plantaginea* var. *grandiflora*, Hort.), grows 1 ft. high, and has large crimson fls. Var. *rosea*, Hubb. (*Armèria plantaginea* var. *rosea*, Hort.), grows 1 ft. high and has pink fls. Var. *rubra*, Hubb. (*Armèria plantaginea* var. *rubra*, Hort.), grows 1 ft. high and has red fls. Var. *splendens*, Hubb. (*Armèria plantaginea* var. *splendens*, Hort.), grows 1-1½ ft. high and has brilliant rose-colored earlier fls. May, June.

12. *S. pseudoarmeria* var. *alba*, Hubb. (*Armèria cephalotes* var. *alba*, Hort.), has white fls. Var. *grandiflora*, Hubb. (*Armèria cephalotes* var. *grandiflora*, Hort.), grows 1½ ft. high and has large heads of rose-colored fls. Var. *rubra*, Hubb. (*Armèria cephalotes* var. *rubra*, Hort.), has rosy red fls. Var. *splendens*, Hubb. (*Armèria cephalotes* var. *splendens*, Hort.), grows about 18 in. high, forming large tufts of foliage and has large heads of vivid rose fls.

13. *S. majellensis*, Hubb. (*Armèria majellensis*, Boiss.). Cespitose, glabrous, base hardened: sheaths persistent, spreading squarrose: lvs. spreading to somewhat recurved, short, stiff, rather broad-linear, margin

cartilaginous, folded to channeled, obtuse, 3-nerved: scapes medium height; heads large; involucre few-rowed, pale. Italy.

15. *S. leucocéphala*, Hubb. (*Armèria leucocéphala*, Salzm. ex Koch). Cespitose, base hardened: sheaths withering: lvs. linear, flat, 1-nerved, margin narrowly excurrent, apex short-mucronate: scape slender, more or less tall: involucre few-lvd., lvs. much shorter than the head: fls. white or rose. Corsica.

Armèria arborea, Hort., is described in the trade as having thick, woody, much-branched sts., each terminating with tufts of grass-like foliage and reddish fls.; unknown botanically.—*A. bracteata*, Hort., is described as a plant about 6 in. high, with bright crimson fls., flowering May–July; possibly equals *Acantholimon bracteatum*, Boiss., which is a cespitose plant, with a compressed, head-like spike, with large ovate-orbicular bracts. Var. *rubra*, Hort., has bright crimson bracts 1–2 in. long.—*A. formosa* var. *alba*, Hort., probably equals *S. pseudoarmeria* var. *alba*. Var. *hybrida*, Hort., is not recognizable from the data at hand.—*A. leucophylla*, Hort., is described as growing 9 in. high and having pale primrose fls.; not known botanically.—*A. magellanica*, Hort., is described as a pretty alpine species with bright rosy crimson fls.

LIMONIUM (Greek, *meadow or marsh*, referring to the place of growth of many species). Syn., *Stidice* of most authors, not of Linn.; *Goniolimon*, *Plumbaginaceæ*. SEA LAVENDER. Mostly perennial herbs, rarely annual or subshrubby, useful for cut-flowers and for the rock-garden.

Leaves usually radical and tufted especially, in the herbaceous species, generally rather long, alternate along the st. in the shrubby species, linear, spatulate oblong or obovate, sometimes pinnatifid or dissected: fls. blue, lavender, white, red, or yellow, in little or much-branched panicles, borne on a leafless peduncle or scape; bracts subtending the fl.-clusters scale-like, somewhat clasping, usually coriaceous on the back, and with membranous margins, usually with 1 or 2 fls. in their axils, sometimes with dense few to several-fl. spikelets; calyx funnel-shaped, often colored, usually the showy part of the fl., and scarious or persistent.—About 180 species well scattered about the world, but mainly seacoast plants of the northern hemisphere and especially numerous in Asia. Limoniums are of easy cult. but prefer a rather deep, loose soil. From the delicate nature of the fl.-panicles the species are better suited to rockwork and isolated positions than for mixing in a crowded border. Many of the species are useful for cut bloom, especially for mixing with other flowers. Some of the species are adapted to greenhouse culture, especially the shrubby forms.

KEY TO THE SUBGENERA AND SECTIONS OF LIMONIUM.

- A. *Stigmas capitata*. Subgenus I. GONOLIOMON. Species 1–5.
- AA. *Stigmas cylindricifolia*.
- B. *Petals united in a tube, undivided*.
- Subgenus III. SIPHONANTHA. Species 30–32.
- C. *Duration perennial*.
- Section I. EUSIPHONANTHA. Species 30.
- CC. *Duration annual or biennial*.
- Section 2. PSYLLIOSTACHYS. Species 31, 32.
- BB. *Petals only united at the very base, if at all, undivided*.
- Subgenus II. VERALIMONIUM. Species 6–29.
- C. *Corolla yellow or yellowish white* (Section 3 contains a few species with rose fls., but none of them occurs in the trade-lists and are probably not in cult.).
- D. *Limb of calyx strongly folded: scape and branches of infl. usually winged or 2-edged-flattened (not winged in Nos. 14, 16, and 18; scape terete at base in No. 7).* Section 1. PTEROCLADOS. Species 6–16.
- DD. *Limb of calyx lobed or erose: scape and branches of infl. angled above; branchlets often articulate*.
- Section 3. PRATHYMENTIUM. Species 18, 19.
- CC. *Corolla rose to purple*.
- D. *Scapes and branches of infl. crisped-winged or acute-angled*.
- Section 2. CTENOSTACHYS. Species 17.
- DD. *Scapes and branches of infl. terete, the branchlets sometimes angled*.

E. *Stigmas* not coiled.

Section 4. *EULIMONUM*. Species 20-28.
EE. *Stigmas* coiled: calyx indurated.

Section 5. *CIRCINARIA*. Species 29.

Subgenus I. GONIOLIMON.

- A. Interior bracts undivided 5. *elatum*
AA. Interior bracts 2-3-cuspidate at the apex.
B. Spikelets 1-2-fl'd.
C. Branches of the panicle recurved 1. *tataricum*
CC. Branches of the panicle incurved 2. *collinum*
BB. Spikelets 3-4-fl'd.
C. Panicle-branches narrowly 2-edged or winged, 3-angled 3. *speciosum*
CC. Panicle-branches terete and pubescent. 4. *eximium*

1. *tataricum*, Mill. (*Statice tatarica*, Linn. *Goniolimon tataricum*, Boiss.). Perennial, glaucescent, about 1 ft. high; lvs. 4-6 in. long, obovate or oblong-lanceolate, very narrowly marginate, abruptly or attenuately mucronate, narrowed to the petiole: scape corymbose-panicled slightly above the base; branches elongate, spreading-recurved, narrowly 3-winged; spikelets 1-2-fl'd., distichously arranged in rather dense terminal spikes: calyx white, green-nerved, tube short-puberulent inside and out, lobes oblong, obtuse, corolla ruby-red. June, July. S. Eu., Caucasus, Russia, and Siberia. B.M. 6537. Var. *angustifolium*, Hubb. (*Statice tatarica* var. *angustifolia*, Hort. S. Besseriàna, Schult. S. *incana*, Bieb., not Linn. S. *incana* var. *hybrida*, Hort.), has, lanceolate, narrower lvs., often 1-fl'd. spikelets, and glabrescent calyx-tube. Var. *coccineum*, Hubb. (*Goniolimon tataricum* var. *angustifolium*, Boiss. *Statice incana* var. *coccinea*, Hort.), grows 9 in. high and has red and white fls. Var. *natum*, Hubb. (*Statice tatarica* var. *nana*, Hort. S. *incana* var. *nana*, Hort. S. *incana* var. *hybrida nana*, Hort.), is a dwarf strain of the species.

3682. *Limonium* (Statice) *Bonduellii*. The flowers are about $\frac{1}{2}$ inch across.

2. *collinum*, Hubb. (*Statice collina*, Griseb. S. Besseriàna, Friv., not Schult. *Goniolimon collinum*, Boiss.). Perennial, glaucescent: lvs. oblong-lanceolate or lanceolate, aristate-mucronate, narrowed to the petiole: scape corymbose-panicled a little above the base; branches 3-angled, spreading-incurved; spikelets 1-fl'd., clustered in numerous short, straight, fasciculate spikes: fls. rose; calyx-tube glabrous, lobes oblong, obtuse. S. E. Eu., Asia Minor, and Syria.

3. *speciosum*, Kuntze (*Statice speciosa*, Linn. *Goniolimon speciosum*, Boiss.). Perennial, glaucescent, about 1 ft. high: lvs. suborbicular or oblong-obovate, abruptly attenuate-cuspidate, shortly narrowed at base: scape densely corymbose above; branches narrowly 2-edged or winged, 3-angled; spikelets 3-4-fl'd., distichously and densely imbricated in short scorpioid-capitate spikes: calyx white, tube densely appressed-pubescent; corolla rose or purplish pink, very deciduous. July. S. Russia, Caucasus. B.M. 656. L.B.C. 14:1336.

4. *eximium*, Kuntze (*Statice eximia*, Schrenk. *Goniolimon eximium*, Boiss.). Perennial, glaucescent, 1-2 ft. high: lvs. oblong or obovate, short-mucronate, narrowly and crisped marginate, long-attenuate to the petiole: scape tall, panicled above; branches terete and pubescent; spikelets about 4-fl'd., densely imbricated in densely scorpioid-capitate spikes: fls. lilac-rose; calyx green, tube appressed-pubescent, lobes white-tipped, rather acute, crenulate. Aug. Cent. Asia. B.R. 33:2. Var. *album*, Hubb. (*Statice eximia* var. *alba*, Hort. S. *eximia flore-albo*, Hort.), has large white fls. Var. *superbum*, Hubb. (*Statice eximia* var. *superba*, Hort.), has large spreading heads of lilac fls. Aug., Sept.

5. *elatum*, Kuntze (*Statice elata*, Fisch. S. *scoparia*, Hort. Vilm., not Pall. *Goniolimon elatum*, Boiss.). Perennial, green, about 2 ft. high: lvs. obovate, very obtuse, apex often retuse, shortly mucronate, rather long-attenuate to the petiole: scape tall, elongate-panicled above; branches hairy, 3-angled, spreading-incurved; spikelets 2-fl'd., loosely imbricated in distichous ovate spikes: fls. blue or violet-blue; calyx-tube appressed, pubescent, lobes rather acute, July, Aug. S. Russia and Siberia.

Subgenus II. VERILIMONIUM.

Section 1. PTEROCLADOS.

- A. Interior bracts 2-3-cuspidate at the apex: wings of the scape produced below the branches into lf.-like linear or lanceolate appendages.
B. Calyx-limb undivided.
C. Limb of calyx blue or purple 6. *sinuatum*
CC. Limb of calyx yellow 7. *Bonduellii*
BB. Calyx-limb deeply 10-lobed 8. *Thouinii*
AA. Interior bracts undivided, truncate: wings of the scape, when present, interrupted below the branches and produced into rotundate auricles: calyx-limb blue, large, erose-truncate.
B. Floral branchlets not winged.
C. Lvs. $\frac{1}{2}$ - $\frac{3}{4}$ in., long 14. *puberulum*
CC. Lvs. much longer.
D. Blades rotundate-triangular, nearly as broad as long, about $2\frac{1}{2}$ in. long 15. *Preauxii*
DD. Blades broad-triangular or rhomboid-ovoid, longer than broad, about 5-6 in. long 16. *Perezii*
BB. Floral branchlets winged.
C. Inner bracts keeled, keel broadened vertically at the top.
D. Lvs. about 4-6 in. long; auricles of the wings below the spikes triangular-falcate 9. *arborescens*
DD. Lvs. about $1\frac{1}{2}$ -2 in. long; auricles of the wings below the spikes rotundate 10. *fruticans*
CC. Inner bracts dorsally convex, with a membranaceous colored limb at the truncate apex.
D. The lvs. entire, obovate-spatulate 11. *macrophyllum*
DD. The lvs. lyrate or lyrate-runcinate.
E. Spikelets 2-fl'd.: calyx-tube glabrous, limb very obtusely 5-denticulate-sinuate 12. *brassicifolium*
EE. Spikelets 3-4-fl'd.: calyx-tube somewhat hirsute, limb truncate-crenulate 13. *imbricatum*

Subsection ODONTOLEPIDEAE.

6. *sinuatum*, Mill. (*Statice sinuata*, Linn.). Perennial or biennial, 1-2 ft. high, the whole plant hispid-scabrous, the hairs from tubercles: lvs. pinnatifid-lyrate, sinuses and lobes rounded, the terminal bearing a bristle: scape dichotomously paniculate-corymbose, 3-5-crimped-winged, the wings below the forks produced into 3 acute, linear-lanceolate appendages; branches 3-winged, the wings gradually broadening from the base; spikelets 3-5-fl'd., in short second spikes: calyx blue or bluish, tube glabrous, limb truncate, crenulate; corolla yellowish white. Aug. Medit. region. B.M. 71. G.W. 7, p. 229.—Usually treated as an annual. Var. *candidissimum*, Hubb. (*Statice sinuata* var. *candidissima*, Hort.), has pure white fls.—A good plant for edging. The material known in the trade as *Statice sinuata hybrida* are hybrid forms of this species.

7. *Bonduellii*, Kuntze (*Statice Bonduelli*, Lest.; also misspelled *Bonduellii*). Fig. 3682. Annual or biennial about 1 ft. or more high: lvs. radical, spreading, 3-5 in. long, spatulate, sinuate-lyrate, hairy and ciliate, terminated by a subulate point, tapering below into a short winged petiole, lobes oval or rounded, sinuses obtuse, terminal lobe largest, subrhomboid: scapes several, dichotomously branched, rounded and hairy at base; branches triangular, wings narrow, sometimes broad, running out below the forks into 2 or 3 linear appendages; branchlets 2-edged or 3-winged, dilated upward, forked at the apex, slightly hairy; spikelets 1-3-fl'd.; bracts with hard green spines, some subulate others semi-hastate: calyx yellow, tube glabrous, limb campanulate, 5-toothed, minutely crenulate; corolla deeper yellow. June-Oct. Algeria. B.M. 5158. F.S. 20:2129. H.F. II. 2:230.—The Calif. material seems to have more broadly winged branches and branchlets than usual.

8. *Thouinii*, Kuntze (*Statice Thouinii*, Viv. S. *egyptiaca*, Pers.). Annual, glaucescent, about $1\frac{1}{2}$ ft. high: lvs. sinuate or pinnatifid-lyrate, lobes and sinuses rounded, margin short-ciliate: scapes corymbose above, more or less broadly 3-winged, wings produced below the upper forks into 1-3 triangular-lanceolate rather obtuse appendages; branches strongly dilated from the base upward, running out into acute triangular appendages below the spikes; spikelets 2-3-fl'd., distichous in short second spikes: calyx white, tube glabrous, lobes 5, triangular-lanceolate acute; corolla yellow. May. Teneriffe and Medit. region. B.M. 2363.

Subsection NOBILES.

9. *arborescens*, Kuntze (*Statice arborescens*, Brouss.). Shrub about 2 ft. high: sts. terete, naked, branched only above: lvs. broad ovate-oblong, petioled, obtuse, mucronate, base attenuate, leathery: scape tall, branched above, broadly and subcorymbosely panicled, with the branches narrowly winged; branchlets very short, 3-winged, the wings narrowly dilated from the base upward and running out into 3 triangular-falcate acute appendages below the spike; spikelets 2-fl'd., laxly imbricated in fascicled short, second spikes: calyx blue, tube glabrous, limb erose-denticulate; corolla yellow. July. Teneriffe. B.M. 3776. P.M. 4:217 (under the name *Statice arborea*).

10. *fruticans*, Kuntze (*Statice fruticans*, Webb. *S. arborescens*, Brouss. *S. frutescens*, Lem.). Shrub: st. short, naked, terete; lvs. at the base of the scape, leathery, ovate, obtuse, mucronate, shortly attenuate to the petiole; scape low, corymbose-panicled above, it and the branches puberulent, strongly compressed; branchlets 2-winged, wings at base very narrow, broadened upward, running out into short, unequal rotundate auricles below the spike; spikelets 1-2-fl., very few, imbricated in very short, secund spikes; calyx blue, tube glabrous, limb acutely erose-dentate; corolla yellow. Summer. Tenerife. F.S. 4:325. H.U. 6, p. 164.—Closely allied to *S. arborescens* from which it differs in the 3 times smaller lvs. which are $1\frac{1}{2}$ -2 in. long, the scapes 4-6 in., 2-edged, not winged and the auricles of the branchlets rotundate.

11. *macrophyllum*, Kuntze (*Statice macrophylla*, Brouss. *S. Halfordii*, Hort.; also spelled *Halfordii*). Subshrub about 2 ft. high: lvs. rather glabrous, very large, sessile, obovate-spatulate, very obtuse, lower part long-attenuate, obsoletely sinuate; scape tall, amply and very much branched, corymbose-panicled above, it and the branches winged; branchlets 3-winged, wings dilated from the base upward, puberulent, net-veined, running out into short obtuse auricles below the spikelets or these may be nearly obsolete; spikelets 2-fl., grouped in 2's, erect at the ends of the branches; calyx blue, tube puberulent, limb very obtuse, 5-crenate-sinuate; corolla yellow or almost white. May. Tenerife. B.M. 4125. B.R. 31:7.—Cult. in S. Calif. Makes a good pot-plant for winter-flowering in a cool greenhouse. T. D. Hatfield, in G. F. 9:496, says: "Old plants are somewhat subject to stem-rot. Plants should be grown in rather undersized pots, in a light soil with which some charcoal has been incorporated, and given perfect drainage, as excessive moisture at the roots is fatal. Propagation is effected by cuttings of the side shoots placed in a cool propagating-bed, or better by layering, which is well accomplished in summer by making a notch in each of the side branches and then burying the plant in ordinary garden soil below the incisions."

12. *brassicifolium*, Kuntze (*Statice brassicifolia*, Brouss.). Fig. 3683. Subshrub, $1\frac{1}{2}$ ft. high: lvs. slightly short-velvety, margin somewhat ciliate, petioled, lyrate, terminal lobe largest, ovate-rotund, often irregularly lobed, very obtusely cuspidate, base subcordate; lateral lobes 2-4, ear-shaped, small, alternate, the bases often confluent; scape angled, paniculate-corymbose above; branches 2-winged, the wings very broad, coarsely undulate-lobate, running out into large auricles below the forks; branchlets 3-winged, wings dilated from the base upward running out into short, falcate auricles, glabrous; spikelets 2-fl., 2-3-fasciated at the ends of the branches; calyx purple, tube glabrous, limb very obtusely 5-denticulate-sinuate; corolla yellowish white. Aug. Canary Isls. B.M. 5162.

13. *imbricatum*, Hubb. (*Statice imbricata*, Webb). Subshrub, about $1\frac{1}{2}$ ft. high, the whole plant shortly soft-tomentellous: lvs. lanceolate in outline, lyrate-runcinate, lobes on both sides 8-9, the upper larger, rotundate, setose-mucronate, 9-10 in. long, the lower lobes remote and retrorse; scape tall, large, corymbose above; branches undulately and broadly winged; branchlets 3-winged, narrowly dilated from the base, running out into short, unequal triangular auricles which are rather obtuse; spikelets 3-4-fl., few, fasciated in short spikes; calyx blue, tube somewhat hirsute, limb truncate-crenulate; corolla yellowish white. July, Aug. Tenerife. F.S. 4:320-321.

14. *puberulum*, Kuntze (*Statice puberula*, Webb). Subshrub, 4-8 in. high, the whole plant white papillate-stellate or sparsely puberulous: lvs. ovate-rhomboid, rather acute, apex bearing a bristle, margin long-ciliate, short-attenuate to the equally long petiole, blade $\frac{1}{2}$ - $\frac{3}{4}$ in. long; scape low, paniculate-corymbose; branches and branchlets angled, somewhat 2-edged; spikelets 2-fl., a few distichously or laxly fasciated at the end of the branches; calyx violet, tube glabrous, limb obsoletely 5-angled, the nerves excurrent; corolla yellowish white. July. Canary Isls. B.M. 3701. B.R. 1450. H.F. II. 9:106.—*L. profusum*, Hubb. (*L. puberulum* $\times$ *L. macrophyllum*, the form known horticulturally as *Statice Halfordii*, *Statice profusa*, Hort.). Subshrub, 1-2 ft. high: lvs. radical, 6-8 in. long, oval or spatulate, wavy, leathery, shining and dark green, narrower than the parents and intermediate in size between them; fls. freely produced in well-branched, corymbose panicles; calyx blue-purple; corolla yellowish white. A greenhouse hybrid. G. 8:69. G.L. 27:77. Gn.W. 22:782.—In the greenhouse old plants will attain a height of $3\frac{1}{2}$ ft. and a diam. of 5 ft.

15. *Preauxii*, Kuntze (*Statice Preauxii*, Webb). Subshrub, 2 ft. high, glabrous: st. terete, naked; lvs. basal, rotundate-triangular, obtuse mucronulate, about $2\frac{1}{2}$ in. long and the same wide, very coriaceous, base truncate and short-attenuate to a petiole 4-5 in. long with a sheathing base; scape angled, branched; branches flattened, scarcely winged; spikelets remote, in lax, rather erect, secund, terminal spikes; calyx-tube glabrous, limb lavender, obsoletely 5-angled; corolla pale yellow. Canary Isls.—Cult. in Calif.

16. *Perèzii*, Hubb. (*Statice Perèzii*, Stapf). Subshrub, less than 2 ft. high: lvs. long-petioled, broadly triangular or rhomboid-ovate, base usually truncate, but short triangular decurrent on the petiole; branches of infl. pubescent; bracts at the base of the branches sulcate-caudate, ciliate; calyx purplish blue, pubescent; corolla pale yellow. Canary Isls.—Cult. in Calif., where it is said to grow 3 ft. high.

Section 2. CTENOSTACHYS.

17. *pectinatum*, Kuntze (*Statice pectinata*, Ait.). Subshrub, glabrous, calcareous-punctate: lvs. in a rosette at the base of the scape or fasciated or solitary at the axils of the scales of the scape, obovate, obtuse or retuse mucronate, attenuate to the petiole; scape erect or decumbent, alternately branched, it and the branches very nar-

rowly 3-angled to winged; spikelets 3-fl. distichously dense-imbricated, in oblong, scorpioid-spreading spikes; calyx lavender, slightly pilose at base of the ribs and limb which is obtusely 5-angled; corolla rose. Sept. Canary Isls. B.R. 26:65.

Section 3. PLATHYMENTUM.

- A. *Lvs. obovate-lanceolate: spikelets 2-fl.* 18. *sinense*
AA. *Lvs. oblong-spatulate: spikelets 4-6-fl.* 19. *australe*

Subsection CHRYSANTHE.

18. *sinense*, Kuntze (*Statice sinensis*, Girard. *S. Fortunei* Lindl.). Perennial, about 1 ft. high, glabrous: lvs. obovate-lanceolate, obtuse, long-attenuate to the petiole; scape tall, dichotomously branched a little above the base, corymbose-fastigiate, it and the branches smooth, acutely angled, often 2-edged; spikelets 2-fl., rather densely imbricated, in short, somewhat secund, terminal, ovate-scorpioid spikes; calyx white or pale yellow, tube pilose only on the ribs, limb 5-angled and folded; corolla yellow. April. China. B.R. 31:63. F.S. 2:92.

19. *australe*, Kuntze (*Statice australis*, Spreng.). Perennial, about 1 ft. high, glabrous: lvs. oblong-spatulate, mucous, long-attenuate to the petiole, 1-nerved; scape acutely angled to sulcate, branched a little above the base; branches elongated, strict, sub-corymbose-panicled; spikelets 4-5-fl., in straight terminal spikes or secund and scorpioid, lower remote; calyx whitish, tube very smooth, limb 5-lobed, lobes ovate, mucronulate; corolla yellow. April. China, Japan, and Austral.

3683. *Limonium* (*Statice*) *brassicifolium*. ($\times\frac{1}{2}$)

Section 4. EULIMONIUM.

- A. *Calyx-limb somewhat 10-lobed, by reason of the minute teeth between the large lobes.*
B. *Blades broadly ovate or obovate* 22. *Gmelinii*
BB. *Blades oblong-lanceolate.*
C. *Lvs. glabrous: calyx white or bluish, tube more or less pilose on the ribs* 20. *vulgare*
CC. *Lvs. tomentellous: calyx-tube reddish velvety* 21. *tomentellum*
AA. *Calyx-limb 5-lobed.*
B. *Plant 1 ft. or more high.*
C. *The lvs. obovate-lanceolate, canaliculate-concave, acuminate* 23. *lychnidifolium*
CC. *The lvs. oblong-elliptical, obtuse* 27. *latifolium*
BB. *Plant 3-10 in. high.*
C. *Apex of lf. acute or rather so* 24. *binervosum*
CC. *Apex of lf. obtuse.*
D. *Tube of calyx slightly puberulent* 26. *minutum*
DD. *Tube of calyx appressed-hirsute or ciliate on the angles.*
E. *Limb of calyx reddish below, whitish above* 25. *Gougetianum*
EE. *Limb of calyx pure white* 28. *reticulatum*

Subsection GENUINAE.

20. *vulgare*, Mill. (*Statice Limonium*, Linn. *S. maritima*, Lam. in part.). Fig. 3684. Perennial, 6-12 in. or more high, glabrous: lvs. oblong-lanceolate, 1-nerved, obtuse, with an incurved mucron from or below the apex, attenuate to a rather long petiole at the base; scape tall, nearly terete, paniculate-corymbose above; spikelets 1-3-fl., distichously and densely congested in secund, more or less

spreading or spreading recurved spikes: calyx white to bluish, tube more or less pilose on the ribs, lobes triangular, rather acute; corolla bluish lilac. Aug. to Oct. Eu., N. Afr., Asia Minor, and Syria. Var. *album*, Hubb. (*Statice Limonium* var. *alba*, Hort.), has a white calyx, height 1 ft. July–Sept. Var. *macrocladum*, Hubb. (*Statice Limonium* var. *macroclada*, Boiss.), is often glaucescent, panicles very much branched, branches elongate, very spreading, spikes laxly or densely scorpioid. Medit. region and Syria.

21. *tomentellum*, Kuntze (*Statice tomentella*, Boiss. *S. sareptana*, Becker). Perennial, about 9–12 in. high: lvs. oblong-lanceolate, obtuse, short-attenuate to the petiole, 1-nerved, densely tomentellous beneath on the nerves, margin somewhat ciliate, otherwise glabrous; scape tall, terete, somewhat angled above, slightly and strictly branched, all densely short reddish tomentellous; spikelets 2–3-fld., distichously and densely aggregated in oblong, second, scorpioid spikes: calyx-tube obovate, reddish velvety, lobes rotund, very obtuse; corolla rose. S. Russia.

22. *Gmelinii*, Kuntze (*Statice Gmelinii*, Willd.). Perennial, 1½–2 ft. high: lvs. glabrous, green, broad-ovate or obovate, 1-nerved, very obtuse, very short-petioled or sessile; scape tall, terete below, somewhat angled above, corymbose-panicled; spikelets rather 2-fld., densely imbricated in short second subscorpioid spikes: calyx-tube pilose on all or some of the ribs, limb small, dark purplish blue, lobes rotundate; corolla rose. July–Sept. Caucasus and Siberia.

Subsection DENSIFLORÆ.

23. *lynchnidifolium*, Kuntze (*S. lynchnidifolia*, Girard. *S. Willdenowii*, Poir.). Perennial, glabrous, about 1–2 ft. high: lvs. large, coriaceous, obovate-lanceolate, canaliculate-concave, acuminate, attenuate to a short petiole which is glutinous at its base: scape tall, alternately and distichously branched above; branches erect-spreading, forming a pyramidal subsecond panicle; spikelets 3–4-fld., distichously and rather densely imbricated in second, spreading-recurved spikes: corolla rose. S. W. Eu. and Morocco.

24. *binervosum*, C. E. Salmon (*L. occidentale*, Kuntze. *Statice binervosa*, G. E. Smith. *S. occidentalis*, Lloyd. *S. aviculata*, Vahl). Cespitose perennial, 6–10 in. high, glabrous: lvs. 1–4 in. long, lanceolate-spatulate, without nerves, rather acute, provided with an elongated bristle below the apiculate apex, long-attenuate to the often longer petiole: scape slender, flexuous, very much branched almost from the base, forming an oblong panicle; spikelets 2–4-fld., rather densely

3684. *Limonium* (*Statice*) *vulgare*.
(× ½)

disposed in slender, straight or erect-spreading short spikes: calyx white; corolla bluish purple. July, Aug. Eu.

25. *Gougetianum*, Kuntze (*Statice Gougetiana*, Girard; also mispelled *Gongetiana*). Perennial, 3–4 in. high, glabrous: lvs. densely rosulate, small, obovate or oblong-spatulate, very obtuse, margin crinkled, revolute, attenuate to the petiole, both surfaces rugulose to somewhat scabrous; scapes dwarf, regularly and subdichotomously alternate, branched almost from the base; branches short, strict, forming a short panicle; spikelets 2–3-fld., densely and distichously imbricated in spreading or erect-spreading, oblong spikes: calyx-tube short, appressed-hirsute, limb reddish below, whitish above; corolla lavender. July, Aug. Italy.—Foliage evergreen, fine for sunny nooks in the rocky.

Subsection STEIROCLADÆ.

26. *minutum*, Kuntze (*Statice minima*, Linn.). Perennial or subshrub, about 9 in. high; glabrous, rarely puberulent, rather cespitose: lvs. rosulate, small, obovate or lanceolate-spatulate, obtuse or retuse; scapes dwarf, slender, branched from the base; branches strict, slender, lower ones sterile, upper corymbose-fasciateg; spikelets 2–3-fld., disposed in lax often fasciculate straight terminal spikes: calyx-tube slightly puberulent or glabrous, limb white, deeply 5-lobed, lobes ovate, plicate, rather obtuse; corolla reddish. July, Aug. S. France.

Subsection HYALOLEPIDÆ.

27. *latifolium*, Kuntze (*Statice latifolia*, Smith. *S. latifolia magnifica*, Hort.). Perennial, 1–2 ft. high, soft-velvety with short stellate hairs: lvs. very large, oblong-elliptical, obtuse, long-attenuate to the petiole: scapes tall, very much branched, terete to angled, panicle large and effuse; spikelets 1-, rarely 2-fld., rather remote, forming lax, slender, second, subrecurved spikes: calyx-tube obovate, short, glabrous or slightly hairy, limb white, 5-lobed, lobes triangular acute; corolla bluish lavender. June, July. Russia, Bulgaria, and Caucasus. G. 1:100; 28:367. Gn. M. 15:162.—Deep-rooting so that it should be given a very deep soil in a sunny position and left undisturbed. Var. *album*, Hubb. (*Statice latifolia* var. *alba*, Hort.), has panicles 2–2½ ft. across: fls. white. Var. *roseum*, Hubb. (*Statice latifolia* var. *rosea*, Hort.), is a form with rose-colored fls.

28. *reticulatum*, Mill. (*Statice reticulata*, Linn. *S. bellidifolia*, Gouan. *S. caspia*, Willd.). Perennial, 4–8 in. high, glabrous, the whole plant granulate-scarious: lvs. obovate or lanceolate-spatulate, often only ½ in. long, obtuse, mucronate or mucosous, attenuate to the petiole; scapes branched from the base, lower branches sterile, capillary and many-forked, articulate, rather strict, upper branches densely floriferous, corymbose-paniculate; spikelets 2–3-fld., densely and distichously clustered in short spikes or subcapitately at the ends of the branches: calyx-tube short-conical, ciliate on the angles, limb white, lobes ovate, rather acute, denticulate; corolla pale lilac. July, Aug. Eu., Caucasus, and Siberia.

Section 5. CIRCINARIA.

29. *purpuratum*, Hubb. (*Statice purpurata*, Linn.). Subshrub 1 ft. or more high, glabrous: sts. short, leafy: lvs. 1 in. long, ½ in. broad, leathery, glaucescent, about 3-nerved, obovate, lanceolate or linear-spatulate, attenuate to a long petiole which is sheathing at the base, entire, obtuse, mucronate; scape tall, terete, smooth or scabrous, dichotomously corymbose; spikelets 1-fld., second and distant along the branches or nearly touching: calyx-tube leathery, terete, obsoletely 10-ribbed, limb 10-lobed, purplish at the top; corolla rose. S. Afr. Var. *longifolium*, Hubb. (*Statice longifolia*, Thunb. *S. purpurata* var. *longifolia*, Boiss.), has lvs. oblanceolate or nearly linear, up to 10 in. long, 2 lines wide, usually much smaller. S. Afr.

Subgenus III. SIPHONANTHA.

Section 1. EUSIPHONANTHA.

30. *cæsium*, Kuntze (*Statice cæsia*, Girard. *S. elegans*, Coss.). Perennial, 1–3 ft. high, the whole plant pruinose with calcareous dots, subtuberculate, bluish gray to whitish: lvs. all radical, small, obovate or retuse; scapes numerous, rather stout, very much branched from the base, lower branches sterile, upper elongated, slender, effuse and much branched, paniculate; spikelets 1-fld., very slender and erect, laxly or subdistichously arranged in few-fld., short, lax spikes: calyx-tube slender, glabrous, limb dirty white, 5-lobed, lobes ovate, obtuse; corolla rose, rather large. May, June. Spain.

Section 2. PSYLLIOSTACHYS.

A. Calyx-tube hispid, limb slightly erose-dentate. 31. *spicatum*
AA. Calyx-tube somewhat glandular-pubescent,
limb 6-toothed..... 32. *Suworowii*

31. *spicatum*, Kuntze (*Statice spicata*, Willd.). Annual, about 6 in. high: lvs. soft, in outline lanceolate-oblong, pinnately parted to runcinate, lobes obtuse, triangular-oblong, alternate, confluent at base; scapes erect, surpassing the lvs., terete, slightly papillose-lanate, bearing long dense cylindrical spikes often interrupted at base or branched; spikelets 2–3-fld., densely clustered; calyx-tube hispid, limb obsoletely erose-dentate; corolla rose or white, lobes ovate. Summer. Caucasus region to Persia. G. 3:155; 11:281.

32. *Suworowii*, Kuntze (*Statice Suworowii*, Regel). Annual, 9–16 in. or more high: lvs. all basal, glabrous, long-lanceolate or oblanceolate, 6–8 in. long, entire or usually coarsely runcinate, the teeth or lobes triangular, acute: scapes several, stout, obtusely angled, bearing a long terminal spike and several distant, sessile lateral ones, 4–6 in. long, nearly ½ in. diam.; spikelets 2–3-fld., crowded: calyx-tube somewhat glandular-pubescent, green, limb 5-toothed, rose-red; corolla tubular, rose-red, lobes ovate-rotund. June, July. W. Turkestan. B.M. 6959. Gn. 72, p. 338. Gn. W. 25:195. J.H. III. 60:149. R.B. 25:97. Gt. 31:1095. Var. *album*, Hubb. (*Statice Suworowii* var. *alba*, Hort.), is a form with white fls. G.M. 56:477. Useful for cut-flowers.—*L. superbum*, Hubb. (*L. Suworowii* × *L. leptostachyum*. *Statice superba*, Regel.). Annual, up to 28 in. high: lvs. bright green, pinnately lobed, midnerve red; scapes 5 or more, erect, covered with fls. almost from the base, winged, the spikes forming a small densely crowded panicle: fls. rose-red. A garden hybrid. Var. *flore-alba*, Hubb. (*Statice superba* var. *flore-alba*, Benary. *S. superba* var. *alba*, Benary), is a form with white fls.

The following species are mentioned in the trade and belong in *Limonium* unless otherwise stated, but cannot be placed in the key or are of minor importance.—*Statice altica*, Hort. ex Don, is unknown botanically, but is said to grow 2½ ft. high and have purple or blue fls. July–Sept.—*Statice Butcheri*, Hort., is offered as having blue fls.—*Statice coccinea*, Hort., is offered in the trade as a perennial.—*Statice excelsa*, Hort., is offered in the trade.—*Limonium leptostachyum*, Kuntze (*Statice leptostachya*, Boiss.), is a glabrous annual: lvs. linear in outline, pinnately parted; segms. linear: calyx-tube appressed-hirsute; corolla white. Persia.—*Statice nana alba*, Hort., is offered in the trade; possibly is a form of *L. tataricum*.—*Statice penduliflora*, Hort., is offered in the trade but is unknown botanically.—*Statice spatulata*, is offered by one firm as having ornamental green lvs. and purple-and-white fls., growing 1 ft. high, flowering July to Sept. and by a second firm as growing 1½ ft. high, with very graceful sprays of blue fls. in July and Aug.—Not really possible to say with certainty what it is, perhaps *L. binervosum*.

F. TRACY HUBBARD.†

STAUNTONIA (named for Sir G. L. Staunton, physician, 1740–1801). *Lardizabalaceæ*. Scandent shrubs, hardy and evergreen, useful for ornamental purposes: lvs. digitately parted, 3–7 lfts.: fls. purple or greenish, in axillary corymb-like racemes, monocious; sepals 6, petaloid, the outer broader; petals none; stamens 6:

berry globose, finally splitting open.—About 10 species, China and Japan.

The stauntonias are beautiful evergreen climbers and well adapted to the soil and climate of the South Atlantic and Gulf regions. Both *S. hexaphylla* and the related *Holbaellia latifolia* (known also as *Stauntonia latifolia*) grow well in the writer's Florida garden, although they are not such very luxuriant climbers as are the allamandas, thunbergias, and bignonias. It requires a few years before they are fully established. They are excellent subjects to be planted on old stumps and on small trees, such as catalpa and mulberry trees, which they perfectly cover in the course of time with their pretty evergreen leaves and their rather insignificant but powerfully fragrant flowers. They will not flourish in dry hot sandy soil, demanding for their welfare rather moist shady spots containing a profusion of humus. A little commercial fertilizer containing a fair amount of nitrogen and potash will also prove very beneficial. The need of some kind of a stimulant is shown by the plant itself, which assumes a rather yellowish cast in the green color of the foliage. A few

3685. *Stauntonia hexaphylla*.
($\times \frac{1}{2}$)

days after it has received some plant-food the foliage shows a very beautiful dark green color. These two species and the beautiful *Kadsura japonica* are valuable additions to the garden flora of the southern states. (H. Nehrling.)

hexaphýlla, Decne. Fig. 3685. A handsome vine becoming 40 ft. high: lfts. oval, about 2 in. long, stalked: fls. in axillary clusters, white, fragrant in spring; berry about 4 in. long, splashed with scarlet. Japan. A.G. 12:139.

F. W. BARCLAY.

STAURÔPSIS (Greek, *cross* and *appearance*, alluding to the shape of the flower). Syn., *Fièldia*. *Orchidaceæ*. Epiphytic herbs with leafy stems and without pseudobulbs, grown in the warmhouse.

Leaves distichous, spreading, leathery, and flat: fls. borne on lateral peduncles in a raceme which is sometimes short, simple and rather large- and few-flid., sometimes long, lax-branched and quite numerous, small-flid.; sepals about equal, free, spreading; petals similar to the sepals; labellum affixed to the base of the column, spreading, concave, not spurred, narrow, the lateral

lobes short, the midlobe rather long-concave and bent in at the tip; column short, thick, not winged and footless; pollinia 2: caps. oblong-clavate, not beaked.—About 10 species, India and China, Malaya and the Philippines. Treatment similar to vanda.

lissochiloides, Pfitz. (*S. Bâtemannii*, Nichols. *Fièldia lissochiloides*, Gaudich. *Vanda lissochiloides*, Lindl. *V. Bâtemannii*, Lindl.). Sts. stout, 1-5 ft. high or more: lvs. 18-24 in. long, broad, coriaceous; scapes 12-20-flid.: fls. about 3 in. across; sepals and petals yellow, densely spotted with red-purple, purplish crimson beneath; labellum 3-lobed, saccate at base, the side lobes erect, buff-yellow or purple-crimson, the midlobe boat-shaped, purple-crimson. Philippines. B.R. 32:59. J.H. III. 52:471. Described also under Vanda.

luchuënsis, Rolfe. Scandent herb with sts. 1 ft. long: lvs. oblong, very shortly 2-lobed, 4-6 in. long: scapes suberect, 6-16 in. long, bearing a many-flid. raceme: fls. showy, yellow with brown spots; sepals oblong; petals somewhat narrower; labellum fleshy, slightly 3-lobed, saccate at base. Liukiu Isls. F. TRACY HUBBARD.

STAURÔSTIGMA (Greek, *cross* and *stigma*, in allusion to the cross or star-shaped stigmas). *Aracæ*. Tuberos stoloniferous herbs, adapted to the warmhouse: lvs. long-petioled, hastate-cordate in outline, pinnately cut or 1-2-pinnately parted, the pinnae sessile, acute: peduncles solitary or several, as long as the lvs.; spathe erect, lanceolate, base convolute, gaping or open above; spadix cylindrical: fls. monœcious, all perfect, the male and female contiguous; perianth wanting: berries subglobose, deeply 2-5-sulcate, 2-5-celled, the cells 1-seeded.—About 7 species, Trop. Amer. The oldest name for this genus is *Asterostigma*. *S. concinnum*, Koch. About 1½ ft. high: young lvs. reniform, pedately cut, the segms. obovate-lanceolate, the older 3-parted, the middle part pinnately cut, elongated-oblong, the lateral parts cymosely bisected or trisected; the petioles marked with pale violet and dark purple; spathe narrow-lanceolate, very acute; spadix white and purple, the male part dense-flid.; peduncle livid purple, shorter than the petioles. Brazil. L.B.C. 16:1590 (as *Caladium luridum*). Variable. *S. Luschnathianum*, Koch (*Asterostigma Luschnathianum*, Schott). Lvs. 1-2 ft. long, deep green, pinnatifid, broadly ovate, the 2 lower segms. deflexed, deeply cut into 3-5 lobes, the remaining segms. 4-6 pairs, sessile, remote; the petioles 6-12 in. long, whitish with black-purple streaks: spathe deep green within and speckled with brown, reticulated externally, 2-4 in. long, erect, cylindric, acute; spadix cylindric; anthers scarlet; ovaries white; scape similar to the petiole. Brazil. B.M. 5972. *S. Riedelianum*, Engl. About 2 ft. high: lvs., the adults, 3-parted, the middle one pinnately cut, the segms. linear-oblong, sessile, abruptly and rather long-cuspidate at the apex; the lower parts short-decurrent: peduncles spotted and variegated: spathe yellowish, greenish outside; spadix slender; peduncles many, variegated. Brazil.

F. TRACY HUBBARD.

STEIRONEMA (Greek, *sterile threads*, referring to the staminodia). *Primulacæ*. LOOSESTRIPE. Erect glabrous herbs useful for borders in damp soil.

Leaves opposite, or rarely whorled, entire: fls. rather large (6-12 lines broad), yellow, axillary, solitary or clustered: peduncles slender: corolla rotate, 5-parted; lobes erose and often cuspidate, each separately involute around its stamen; stamens 5, opposite the lobes, with 5 alternating subulate staminodia; filaments distinct, or nearly so; ovary superior, 1-celled with free central placenta, becoming capsular in fr.; seeds many; style and stigma 1. Differs from *Lysimachia* in the presence of the sterile stamens, and in the æstivation of the corolla.—About 5 species, N. Amer. All perennials. Offered by collectors of native plants, for colonizing, borders and wild-gardens.

A. *Lvs. membranaceous with pinnate veins.*

ciliatum, Raf. (*Lysimachia ciliata*, Linn.). St. 1-4 ft. high, sparingly branched: lvs. 2-6 in. long, ovate-oblong to ovate-lanceolate, acute or acuminate; base rounded or subcordate; petioles $\frac{1}{2}$ in. long, coarsely ciliate. Moist thickets, U. S.

lanceolatum, Gray (*Lysimachia lanceolata*, Walt. *L. hybrida*, Michx.). Plant 1-3 ft. high: lvs. lanceolate, 1-4 in. long, narrowed into a short margined petiole, or subsessile, the lower sometimes broader. E. U. S.

AA. *Lvs. firm, linear, usually 1-nerved.*

quadriflorum, Hitchc. (*Lysimachia quadriflora*, Sims. *L. longifolia*, Pursh. *S. longifolium*, Gray). St. 4-angled, 1-3 ft. high: lvs. thick and firm, sessile, subacute at both ends, 1-4 in. long, smooth and shining; margins slightly revolute; basal often broader; veins obscure. E. U. S. B.M. 660. K. M. WIEGAND.

STELIS (an old Greek name used by Theophrastus for some parasitical plant). *Orchidaceæ*. Epiphytic herbs, some of them adapted to the warmhouse and others to the intermediate house: sts. caespitose or creeping, with simple branches 1-lvd. at the tip and frequently 1-3-sheathed below the lf., not pseudobulbous: lvs. leathery, often contracted at the base to the petiole which is frequently concave or channeled and sometimes articulate near the base: fls. small to minute, short-pedicelled in an elongated raceme at the base of the terminal lf., secund, rarely somewhat distichous; bracts alternate, various; sepals frequently subequal, broad or triangular, spreading, more or less connate; petals much shorter, broad, the margins thickened; labellum sessile at the base of the column, equal and similar to the petals or narrower and sometimes shortly 3-lobed; column equaling or shorter than the labellum; pollinia 2: caps. small, ovoid or oblong, not beaked, often 3-edged.—About 200 species, Mex. and W. Indies southward to Brazil and Peru. Treatment the same as for *Pleurothallis*.

S. barbata, Rolfe, is a species differing from *S. Endressii* in having long-bearded sepals and a tridentate lip: fls. are greenish ochre-yellow with purple hairs and red-purple blotches. Costa Rica.—*S. Binotii*, Wildem., grows about 2 in. high: lvs. thick, 2-3 in. long, deeply channeled above: racemes 1-3, many-fl.: fls. green, not spotted; sepals membranaceous; petals concave, very short; lip hooded, about as long as the petals. Brazil.—*S. Bruchmülleri*, Reichb. f., has lvs. $1\frac{1}{2}$ -2 in. long: fls. yellowish purple outside, pale purple within, disposed at intervals along the rachis; sepals broadly ovate, acute, spreading, hairy within; petals and lip minute, the latter undivided. Mex. (?) B.M. 6521.—*S. canaliculata*, Reichb. f., is about 8 in. high, has cuneate-oblong, obtuse, thick lvs. which are plainly channeled in the middle: fls. dull yellowish green, very small, secund in dense racemes; bracts and rachis whitish. Colombia.—*S. citrifolia*, Lindl. (*S. atropurpurea*, Hook.), grows about 6 in. high: lvs. broadly oblong, narrowed at base: spike naked half way then closely fld.: fls. deep purple; sepals ovate, long-fringed; petals compressed-rhomboid, fleshy; lip ovate, fleshy, channeled at base. Mex. B.M. 3975.—*S. dolichopus*, Schlechter, has sts. about 6 in. high: lvs. rather thick, oblong-ligulate, up to nearly 4 in. long: raceme only $1\frac{1}{4}$ -1 $\frac{1}{2}$ in. long: fls. pale yellow. Probably Colombia.—*S. Endressii*, Reichb. f., has lvs. cuneate, oblong-ligulate, obtuse, emarginate and apiculate, thick: raceme distichous: fls. greenish white; sepals coalescing toward the base; lip fleshy, transversely subrhomboid, excavated. Costa Rica.—*S. glóssula*, Reichb. f., is densely tufted: lvs. cuneate, oblong-ligulate, minutely bilobed with a small tooth at apex: fls. brownish, in 2 transverse rows; the upper sepal having a longer extent than the whole of the other floral organs together; lip fleshy, papilliform. Costa Rica.—*S. grandiflora*, Lindl., has sts. 3 in. high: lvs. oblong, petioleate, emarginate, $4\frac{1}{2} \times 1$ in.: spike dense; spathe large, acuminate: fls. chocolate-colored, large for the genus; sepals equal, obtuse; petals ovate; lip ovate, concave, emarginate. Brazil.—*S. grossilabris*, Reichb. f. Plant tufted: lvs. cuneate, spatulate, obtuse: racemes shorter than the lvs.: fls. light greenish, small; lip thick and fleshy. Hab. (?)—*S. Hennisiana*, Schlechter, has slender sts. up to $2\frac{1}{2}$ in. long, 1-lvd.: lvs. lanceolate-ligulate, about 3 in. long, petiole $1\frac{1}{4}$ in. long: racemes slender, 1-sided, many-fl., usually slightly longer than the lvs.: fls. dark purple-red. Colombia.—*S. macroglóssa*, Hort., is offered in the trade.—*S. micrantha*, Swartz, grows 3-6 in. high: lvs. lanceolate-oblong, rather blunt, 1-2 $\frac{1}{2}$ in. long: raceme slender, spike-like: fls. whitish, red within, nodding, 1-sided-distichous; sepals deltoid; petals and lip truncate. Jamaica. L.B.C. 11: 1011.—*S. ophioglossoides*, Swartz, has the st. shorter than the lvs., which are $2\frac{1}{2}$ -6 in. long, oblong-linear, rather blunt, long-tapering at the base: raceme slender, 1-sided, pedunculate: fls. greenish, with a tinge of purple, minute. W. Indies. B.R.

935. L.B.C. 50: 442.—*S. sesquipedalis*, Lindl., is about 6 in. high: lvs. broadly oval, shortly petioleate, $1\frac{1}{2}$ -4 in. long: spike 7-10 in. long: fls. pale yellow, secund, large; sepals roundish ovate, obtuse; petals oblate; lip oblate, hooded. Venezuela.—*S. venosa*, Hort., said to have 6 lvs., is offered in the trade.—*S. zonata*, Reichb. f., has a short st.: lvs. very thick, cuneate-oblong, blunt: raceme 1-sided: fls. light ochre; sepals brown at base; petals with a mauve middle zone. Guiana.

F. TRACY HUBBARD.

STELLARIA (Latin, *star*, referring to the form of the flower). *Caryophyllaceæ*. Annual or perennial herbs, mostly diffuse, tufted or weakly ascending, glabrous or pubescent, of little cultural value.

Leaves opposite, simple: fls. usually white, in terminal or axillary, naked or leafy paniculate cymes or rarely subsolitary; sepals 5, very rarely 4; petals just as many as the sepals, 2-cleft or rarely laciniate or only emarginate; stamens 10 or fewer by abortion; ovary 1-celled: caps. globose, ovoid or oblong, dehiscent by as many or twice as many teeth as there are carpels.—About 100 species, scattered all over the world but chiefly in the temperate regions.

A. Fls. 7-10 lines across.

Holosteia, Linn. **EASTER BELL**. A hardy perennial, erect, 6-18 in. high, simple or somewhat branched, from a creeping rootstock: lvs. sessile, lanceolate, 1-3 in. long: fls. white, abundant, in a terminal leafy panicle; sepals one-half or two-thirds as long as the petals. May, June. Eu., Asia. B.B. 2: 22.—This and the next are desirable for dry banks where grass will not grow well and for other carpeting purposes.

AA. Fls. 2-5 lines across.

B. *Lvs. narrow.*

3686. *Stellaria media*.
(Flower $\times 3$)

graminea, Linn. A slender-stemmed, hardy perennial plant not usually over 6 in. high, from a creeping rootstock: lvs. sessile, linear-lanceolate, usually about 1 in. long: fls. white, in terminal or lateral scarious bracted open panicles; sepals and petals nearly equal in length. May, June. Eu.; naturalized in Amer. B.B. 2: 23. Var. **aurea**, Hort., **GOLDEN STITCHWORT**, has pale yellow lvs. and is lower and more matted in growth. Well adapted for sandy banks where grass does not grow well.

BB. *Lvs. ovate.*

media, Cyrill. **CHICKWEED**. Fig. 3686. A low, decumbent annual weed common in all rich, moist, cult. soils, especially troublesome during the cooler months of the growing season and in frames, and the like, during winter. Lvs. 2 lines to $1\frac{1}{2}$ in. long, the lower petioled, the upper sessile: fls. axillary or in terminal leafy cymes; sepals longer than the petals. Eu., Asia; naturalized. B.B. 2: 21.—It is considered to be a good fall and winter cover-plant in orchards and vineyards, but is never cult. It is a surface-rooting plant.

F. W. BARCLAY.

STEMONA (Greek, *stamen*, alluding to the foliaceous stamens). Syn., *Rozburghia*. *Stemonaceæ*; by some the family is called *Rozburghiaceæ*. Tall climbing perennial herbs, from a tuberous fusiform root, suitable only for the warmhouse: lvs. opposite, alternate or whorled, ovate, 3-9-costate: fls. solitary, or few and subracemose; perianth-segms. 4, lanceolate, many-nerved; stamens subhypogynous, the connectives produced in very long linear-lanceolate appendages; ovary free: caps. ovoid or oblong.—About 15 species, India, China, and Malaya

to Austral. *S. Cúrtisii*, Hook. f. St. twining, leafing and flowering at the same time: lvs. 4-5 in. long, alternate; the petiole very long and slender: fls. small, apparently unisexual. India. B.M. 7254. Similar to the following. *S. tuberosa*, Lour. (*S. gloriosoides*, Voigt. *Roxburghia gloriosoides*, Jones. *R. gloriosa*, Peers. *R. viridiflora*, Smith). Tubers cylindric, 6-12 in. long: st. woody below, twining, leafing and flowering at the same time; branches terete: lvs. 4-10 in. long, broadly ovate-cordate, acuminate, membranaceous, shining: peduncle 1-2 in. long, usually 2-fld.: fls. erect, fetid; perianth spreading and revolute, segms. lanceolate, acuminate, greenish with many purplish nerves: caps. ovoid-oblong, 5-8-seeded. India and Assam. F.S. 2:86. B.M. 1500. H. U. 3, p. 353. The plants are allied to the lily family.

STENÁCTIS: *Erigeron*.

STENÁNDRIUM (Greek, *narrow anthers*). *Acanthaceæ*. Nearly stemless or short-stemmed herbs, frequently villous or pubescent, adapted to the warm- or coolhouse: lvs. often radical or clustered at the base of the st., very entire: spikes scape-like, peduncled, dense or interrupted: fls. usually small at the axils of the opposite bracts, solitary, sessile, spicate; calyx 5-parted, segms. narrow, acute; corolla-tube slender, cylindrical, limb oblique, 5-lobed, lobes obovate, retuse; stamens 4, didynamous: caps. oblong or subfusiform, subterete, 4-seeded or by abortion fewer-seeded.—About 30 species, Trop. and Subtrop. Amer.

Lindenii, N. E. Br. A low-growing compact plant, with broadly elliptical lvs. rounded at the apex and long-attenuate on the petiole, velvety in appearance, of a dark green with a feathering of white or yellow along the veins, somewhat purplish underneath: spikes 2-3 in. long, narrowly cylindrical: fls. not showy, about $\frac{3}{4}$ in. long, yellow: bracts ovate, acute, serrate, green. I.H. 38:136; 40:173 (4). G.W. 3, p. 160.—Tender foliage plant. F. W. BARCLAY.

STENÁNTHIUM (Greek, *narrow flower*; referring to perianth-segments). *Liliaceæ*. Bulbous plants, useful both out-of-doors and in the greenhouse.

Stems erect, tall, simple except for the infl.: lvs. radical or at the base of the st. long, linear or linear-lanceolate, smaller upward along the st. or none: fls. polygamous, whitish, greenish or dark purple, sometimes in lax slightly branched racemes, sometimes very numerous and smaller in pyramidal panicles, pedicelled, frequently nodding; perianth narrowly or broadly campanulate, persistent, segms. connate at base in a very short, turbinate tube, spreading above, narrow or lanceolate, acuminate, 3-7-nerved; stamens 6; ovary ovoid, 3-celled: caps. ovoid-oblong, partially dehiscent into 3 carpels.—About 5 species; one native of Sachaline Isl., another Mexican, the others W. American.

occidentale, Gray. St. slender, 10-20 in. high: lvs. linear-lanceolate, acuminate, 6-10 in. long: raceme simple or branched at base; pedicels slender, spreading or recurved: fls. campanulate, nodding, brownish purple; perianth-segms. 6-8 lines long, oblong to lanceolate, acuminate. Rocky banks, Ore. to Brit. Col. and Idaho.

robustum, Wats. Sts. stout, 3-5 ft. tall, usually very leafy: lvs. often 1 ft. long, lower 4-10 lines broad, upper reduced to bracts: panicle dense, usually compound, branches spreading or ascending: fls. greenish or white, 6-8 lines broad: caps. ovoid-oblong. Moist soil, Pa. and Ohio to S. C., Tenn., and Mo. B.B. (ed. 2) 1:490. Gn. 68, p. 177; 74, p. 513. G.W. 14, pp. 676, 677. F.E. 22:440. F. TRACY HUBBARD.

STENIA (Greek, *narrow*, alluding to the form of the pollen-masses). *Orchidaceæ*. Epiphytic herbs with short sts. and clustered pseudobulbs which bear 1-2 lvs., grown occasionally in the warmhouse: lvs. oblong or narrow, leathery, midrib prominent: scapes short at

the axils of the sheaths, below the lvs. or pseudobulbs, recurved, with 1 rather large fl.; sepals subequal, free among themselves, spreading, the lateral a little broader; petals similar to the dorsal sepals; labellum continuous with the foot of the column, imbricate, fleshy, broad, concave, nearly saccate, the lateral lobes minute, midlobe undivided or all broader and fimbriate; column rather thick and erect; pollinia 4, oblong-linear: caps. unknown. Two species, Trop. S. Amer. Treatment much as in *maxillaria*. *S. guttata*, Reichb. f., is similar to the following, but differs in having blunter sepals and petals which are straw-colored with purple spots and in the lip being blotched and having only seven callous teeth. Peru. *S. pallida*, Lindl. St. wanting: lvs. 2-5, oblong, acute, slightly narrowed and keeled at the base, sheathed with brownish spathaceous scales: scapes radical, prostrate: fls. pale citron-color, $1\frac{1}{2}$ in. or more diam.; sepals and petals linear, acute; lip spotted with red, nearly saccate, entire, fleshy, ovate. Guiana. B.R. 24:20. F. TRACY HUBBARD.

STENOCÁRPUS (Greek, *narrow fruit*, referring to the follicles, which are long and narrow). *Proteaceæ*. Trees, sometimes grown in the warmhouse or the greenhouse.

Leaves alternate or scattered, entire or deeply pinnatifid with few lobes: peduncles terminal or in the upper axils, sometimes several in an umbel or short raceme, each bearing an umbel of pedicellate red or yellow fls.; bracts none or falling off early: fls. hermaphrodite; perianth slightly irregular, tube opening along the lower side, limb nearly globular and recurved; segms. at length separating; anthers broad, sessile within the concave laminae; ovary stipitate, ovules several, imbricate downward in 2 rows: follicle usually narrow, coriaceous.—About 18 species, 3 endemic to Austral., the others natives of New Caledonia.

Cunninghamii, R. Br. Tall, bushy shrub or small tree, glabrous or the infl. slightly pubescent: lvs. about 2-4 in. long, oblong-lanceolate, obtuse or acuminate, tapering to a short petiole, faintly 3-5-nerved: ovary glabrous, fls. otherwise as in *S. salignus*. Austral.

salignus, R. Br. Moderate-sized tree, glabrous or the infl. minutely pubescent: lvs. 2-4 in. long, in the typical form ovate-lanceolate or elliptical, acute, acuminate or rarely obtuse, tapering to a short petiole: peduncles slender, bearing an umbel of 10-20 fls., occasionally up to 30 fls.: fls. greenish white; perianth usually less than $\frac{1}{2}$ in. long; ovary slightly silky-pubescent or nearly glabrous. Austral. B.R. 441.—Cult. in Calif.

sinuatus, Endl. (*S. Cunninghamii*, Hook., not R. Br.). Tree said to grow to a height of 60-100 ft., glabrous or the infl. minutely tomentose: lvs. petioled, either undivided, oblong-lanceolate and 6-8 in. long, or pinnatifid and over 1 ft. long, with 1-4 oblong lobes on each side, mostly obtuse, quite glabrous, but reddish beneath, penninerved and minutely reticulate: peduncles terminal, either 2 or more together in a general umbel or several at some distance forming a short broad raceme, each peduncle 2-4 in. long, bearing an umbel of 12-20 bright red fls.: perianth 1 in. long; ovary densely pubescent on a glabrous stipe. Austral. B.M. 4263. F.S. 3:189. P.M. 14:1. F. TRACY HUBBARD.†

STENOCHLÆNA (Greek, *narrow and covering*). *Polypodiaceæ*. A genus of tropical ferns with long climbing sts. and with usually 1-pinnate lvs.: fertile lvs. much reduced in tissue, and bearing the sporangia entirely covering the under sides, sometimes spreading over the margins. The general relationship of the species is with *Lomaria*, but owing to the way in which the sporangia are borne, they have often been referred to *Acrostichum*. Culturally they belong with epiphytic plants; they do best on tree fern stems and the like.

palústris, Bedd. (*S. scândens*, J. Smith). Rootstock widely climbing: lvs. 1-3 ft. long, with pinnæ 4-8 in. long; fertile pinnæ slender, 6-12 in. long; texture leathery. India. S. 1:224.—A vigorous grower and coarse feeder, much used in cooler houses of large ferneries. It will form a mass of rootstocks several feet long if grown on a fern stem, producing a large number of the rather pale lvs.

sorbifolium, Linn. Rootstock climbing, often prickly: lvs. 12-18 in. long, 6-12 in. wide, with close veins; fertile pinnæ 2-4 in. long, narrow. E. and W. Indies to Brazil.

R. C. BENEDICT.

STENOGLÓTTIS (Greek, *narrow and tongue*, referring to the narrow lip). *Orchidaceæ*. Terrestrial herbs, with short sts. and tuberiferous or thickened fleshy fasciculate roots, which are suitable for the intermediate house, but not commonly cult.: lvs. radical, numerous, rosulate or tufted: fls. small, short-pedicelled, arranged in loose somewhat 1-sided racemes; bracts small; sepals free, subequal; petals somewhat narrower than the sepals and suberect; lip continuous with the base of the column, cuneate-oblong without a spur, 3-5-cleft at the apex; column very short and broad; pollinia granular: caps. oblong, erect. Three species, Trop. and S. Afr. *S. fimbriata*, Lindl. Lvs. numerous, oblong or narrowly lanceolate-oblong, acute, bright green, usually with few or numerous blackish or purple-black blotches: scapes erect, slender, 6-12 in. high: racemes $1\frac{1}{2}$ -6 in. long, lax, many-fl.: fls. light purple with a few elongated dark purple blotches on the lip; sepals broadly ovate, obtuse or subacute; petals ovate, subacute; lip linear-oblong, 3-cleft or 3-parted: caps. narrowly oblong. S. Afr. B.M. 5872. *S. longifolia*, Hook. f. Lvs. numerous, ensiform, or linear-oblong, acuminate, uniformly light green, 3-7 in. long: scapes erect, often stout, 9-21 in. high, with numerous linear-lanceolate, somewhat recurved sheaths; racemes 4-10 in. long, many-fl.: fls. light purple with a few minute darker dots on the lip, occasionally white; sepals broadly ovate, subobtus; petals ovate, subacute; lip linear-oblong, 5-fid or 5-parted. B.M. 7186. G.C. III. 16: 563. G.W. 14, p. 653.

F. TRACY HUBBARD.

STENOLÓBIUM: *Tecoma*.

STENOLÔMA (Greek, *narrow-fringed*). *Polypodiaceæ*. A generic name for a group of tropical ferns now referred to *Odontosoria*, which see.

STENOMÉSSON (Greek, *small and middle*, alluding to the corolla-tube, which is usually contracted near the middle). *Amaryllidaceæ*. Bulbous herbs grown in the warm- or coolhouse.

Leaves developing with the fls., linear or broadly strap-shaped: fls. in several umbels, rarely reduced to one, pedicels often recurved, making the fls. pendulous; involucre bracts 2; perianth red, golden, or tawny, tube elongated, subcylindrical, slightly contracted above the base or toward the middle, lobes erect or more or less spreading; ovary 3-celled: caps. subglobose or 3-furrowed, loculicidally 3-valved; seeds black.—About 22 species, Trop. Amer.

Stenomessons require a good soil and a sunny house with a temperature never below 45°. During the growing season they should have plenty of water, but when at rest comparative dryness is necessary. The offsets should be removed from the old bulbs before growth commences. The plants continue in bloom a number of weeks in spring and summer.

A. *Style shorter than the perianth.*

incarnatum, Baker (*Coburgia incarnata*, Sweet). A tender plant: bulb globose, 2-3 in. through: lvs. thick, glaucous, obtuse, about $1\frac{1}{2}$ ft. long, strap-shaped: scape 2 ft. high: fls. $2\frac{1}{2}$ -3 in. long, few to many in an umbel,

variable in color but typically crimson, with a green spot on each segm. Aug. Peru. I.H. 38:123 (perianth-limb light yellow). Gn. 50:62.

AA. *Style longer than the perianth.*

flavum, Herb. A tender plant: bulb somewhat globose, 1 in. through: lvs. about 1 ft. long, oblanceolate, obscurely petioled, at first compressed on the margin: scape 1 ft. high: fls. bright yellow, $1\frac{1}{2}$ -2 in. long, usually few in an umbel. B.M. 2641. B.R. 778 (as *Chrysiphiala flava*).

F. W. BARCLAY.

STENORHYNCHUS (Greek for *small and beak*). *Orchidaceæ*. Terrestrial plants: scape arising from a rosette of lvs., bearing a raceme or spike: fls. with a distinct chin; dorsal sepal and petals forming a helmet, parallel; lip with a broad base and narrower apex, the base surrounding the column; beak narrow and long.—About 10 species, in Trop. and warm Temp. Amer.

speciosus, Rich. (*Spiránthes colorata*, N. E. Br. *S. colorans*, Hemsl.). Lvs. elliptic, green: bracts acuminate, oblong-lanceolate, as long as fls.: fls. crimson. Trop. Amer. B.M. 1374 (as *Neottia speciosa*).

GEORGE V. NASH.

STENOSPERMATION (Greek for *small and male element*). Sometimes written *Stenospermátium*. *Araceæ*. Climbing warmhouse plants: lvs. with long-sheathed petioles; blades elliptic or lanceolate, inequilateral, the primary lateral nerves numerous, ascending: peduncles rather long, at first nodding at apex, later erect: spathe convolute, at length expanding; spadix stipitate, cylindric, white: fls. perfect; stamens 4.—About 20 species, natives of the Andes of Peru and of N. Brazil.

multiovulatum, N. E. Br. Three to 6 ft. tall: blades 12-16 in. long, 4-6 in. wide, oblong or narrowly elliptic-oblong, coriaceous, opaque green, paler beneath: peduncle 12-18 in. long: spathe 5-6 in. long; spadix $4\frac{1}{2}$ -6 $\frac{1}{2}$ in. long. Colombia.

GEORGE V. NASH.

STENOTÁPHRUM (Greek, *stenos*, narrow, and *taphros*, a trench, the spikelets being partially embedded in the rachis). *Gramineæ*. Creeping grasses with compressed culms, flat divergent blades and narrow flat spikes: spikelets as in *Panicum*, imbedded in the surface of a broad rachis forming terminal spikes.—About 3 species of tropical regions, one species found along the Gulf coast, especially in Fla., where it is utilized as a lawn grass. In this respect it is similar to Bermuda-grass, being naturally adapted to a sandy soil, which it binds by its rhizomes and creeping habit as does that grass.

The introduced form of St. Augustine grass is one of the most valuable lawn grasses for the extreme South. It will grow on almost any soil and thrives even in shade. The leaves are rather broad, never over 6 inches high and require little mowing. This grass does not become coarse, does not hold dew or rain, and is particularly good for house lots and lawns. It does not

3687 *Stenotaphrum secundatum*. ($\times \frac{1}{4}$)

need as much water as Bermuda or St. Lucie grass. It is propagated mostly by cuttings. (E. N. Reasoner.)

secundatum, Kuntze (*S. americanum*, Schrank). *St. AUGUSTINE GRASS*. Fig. 3687. Flowering branches erect, 6-12 in. high. Var. **variegatum**, has lvs. striped with white, and is used as a basket-plant. *G.W.* 15:681 (as *S. glabrum*). Dept. Agric., Div. Agrost. 20:42.

A. S. HITCHCOCK.

STEPHANÁNDRA (Greek, *stephanos*, crown, and *aner*, *andros*, male stamen, alluding to the persistent crown of stamens). *Rosaceæ*. Ornamental shrubs grown chiefly for their handsome graceful foliage.

Deciduous: lvs. alternate, lobed and serrate, stipulate; fls. slender-pedicelled, small, with cup-shaped calyx-tube; sepals and petals 5; stamens 10-20: carpel 1; pod with 1 or 2 shining seeds, dehiscent only at the base.—Four species in China and Japan. Closely allied to *Neillia* and distinguished chiefly by the cup-shaped calyx-tube and the incompletely dehiscent 1-2-seeded pod.

The *stephanandras* in cultivation are low graceful spreading shrubs with slender more or less zigzag branches, bright green medium-sized or rather small lobed leaves and small white flowers in loose terminal panicles. They are hardy as far north as Massachusetts, but *S. incisa* is sometimes killed back in severe winters; it grows, however, freely from the base and is not injured in its appearance except that it remains rather low. They are well adapted for borders of shrubberies or rocky banks on account of their graceful habit and handsome foliage. Propagation is by greenwood cuttings under glass, which root readily, and by seeds; also by division, and *S. incisa* by root-cuttings with bottom heat in early spring.

incisa, Zabel (*S. flexuosa*, Sieb. & Zucc.). Fig. 3688. Shrub, to 8 ft. high, but usually lower, almost glabrous, with angular spreading distinctly zigzag branches: lvs. triangular-ovate, cordate or truncate at the base, long-acuminate, incisely lobed and serrate, the lower incisions often almost to the midrib, pubescent only on the veins beneath and grayish green, $\frac{3}{4}$ -1½ in. long: fls. white, about $\frac{1}{6}$ in. across, in terminal, short, 8-12-fld., usually paniced racemes; stamens 10. June. Japan, Korea. *Gn.* 55, p. 141.—“Closely allied to *Spiræa* and has the *spirea* style of beauty. It has long, slender branches which are densely and regularly interwoven in a fan-like manner. Its habit of growth is fountain-like, the branches being gracefully pendent. Its fls. are snowy white and, although minute, are so numerous that the plant becomes very showy. It is especially fitted for the back of herbaceous borders or for the front of larger shrubs. Its foliage, which is deeply toothed, is tinted red in early spring and deep glossy green during spring and summer. In the autumn it puts on unusual tints of reddish purple. The foliage becomes so dense that the growth of weeds beneath its thickly set branches is effectually prevented. Prop. by cuttings and layers.” (J. W. Adams.)

3688. *Stephanandra incisa*. ($\times \frac{1}{4}$)

Tanákæ, Franch. & Sav. (*Neillia Tanákæ*, Franch. & Sav.). Fig. 3689. Shrub, 5 ft. high, almost glabrous: lvs. triangular-ovate, slightly cordate at the base, abruptly long-acuminate, usually 3-lobed and doubly serrate or lobulate, pubescent only on the veins beneath, 1½-3 in. long: fls. in terminal loose panicles, slender-

3689. *Stephanandra Tanakæ*. ($\times \frac{1}{2}$)

pedicelled, $\frac{1}{6}$ in. across; stamens 15-20. June, July. Japan. *B.M.* 7593. *Gt.* 45:1431. *G.W.* 4, p. 6.—Handsome shrub much resembling *Neillia* in foliage, coloring in fall brilliant orange and scarlet or yellow.

ALFRED REHDER.

STEPHANIA (perhaps a personal name; or by some derived from the Greek word for a garland or crown). *Menispermaceæ*. More than 30 climbing shrubs (rarely herbs) of the Old-World tropics, as defined by Diels in Engler's *Das Pflanzenreich*, hft. 46 (IV. 94), 1910, differing from *Cocculus* in the solitary ovary, often more than 3-merous fls., and a nearly basal rather than nearly terminal style-scar: lvs. usually peltate: fls. in axillary, simple or compound clusters, diclinous; males with 6-10 free sepals, 3-5 fleshy petals, and 6 connate anthers; females with 3-5 sepals, petals like those of the males, 1 ovary with 3-6-parted style: fr. a glabrous drupe with ring-like seed. The species are little known in cult., although the following may be expected in southern regions or sometimes under glass as an ornamental climber. *S. herandifolia*, Walp., in India, Austral., Afr., and Malaya, has striate glabrous branches, and ovate or somewhat deltoid obtuse or acute more or less pubescent lvs. 3-6 in. across: fls. in capitate peduncled puberulent umbels of 8-12 rays: drupes red. *S. japonica*, Miers (*Cocculus japonicus*, DC.), a common roadside weed in parts of China and Japan, has glabrous lvs. and infl.; probably not cult.

STEPHANOPHYSUM (Greek, *crown* and *bladder*, in reference to the shape of the crown). *Acanthaceæ*. Herbs with more or less dentate or entire lvs., the fls. in lateral umbellate cymes: fls. red; calyx 5-parted; corolla-tube short, the lobes erect or more or less spreading; stamens 4, didynamous: caps. contracted from the base to the middle. Trop. Amer. with the exception of the below-mentioned. The genus is now included in *Ruellia*. *S. Barkiei*, Hook. Subshrub, 2-3 ft. high, branches 4-angled, opposite: lvs. opposite, about 6 in. long including the petiole, ovate-lanceolate, entire, acuminate, attenuate at base: panicle terminal, many-fld.: fls.

opposite, sessile, scarlet; calyx-segms. narrow, erect, linear-subulate; corolla more than 2 in. long, tubular-funnelform, curved, the lobes triangular; ovary sunk in a large, fleshy, cup-shaped disk. Trop. Afr. B.M. 5111. H.F. II. 3:162.—This species is apparently not known today and has not been recently treated in works on Trop. Afr.

3690. *Stephanotis floribunda*. ($\times \frac{1}{4}$)

STEPHANOTIS (from Greek words for *crown* and *ear*, alluding to the five ear-like appendages on the staminal crown). *Asclepiadaceæ*. Twining glabrous shrubs of the Old-World tropics, of about fifteen species, one of which, *S. floribunda*, is one of the best of greenhouse climbers.

Leaves opposite and coriaceous; fls. large and showy, white, in umbel-like cymes from the axils; calyx 5-parted; corolla funnelform or salverform, the tube cylindrical and usually enlarged at the base and sometimes at the throat, the lobes 5; crown mostly of 5 scales that are usually free at the apex and adnate to the anthers on the back, the anthers with an inflexed tip or membrane; fr. a more or less fleshy follicle.

There are few plants that have all the good qualities of *S. floribunda*. It is a splendid grower, has good foliage, is very free-flowering, and the flowers last well on the plant or when cut for decorative work. Cuttings are secured from half-matured wood, and can be rooted at any time of year, although spring is the most convenient time. Pot the cuttings singly, in small pots, in a sandy mixture of peat. Place them in a tight case in 70° night temperature. Shade them from the sun and keep the cuttings in a moist condition until they begin to grow. When the small pots are filled with roots, shift them into two or three sizes larger, in a good strong fibrous loam with enough sand added to keep the soil porous. When the shoots have grown to a height of about 2 feet, cut them back several joints. This will make the plants break into several leads. As *S. floribunda* comes from Madagascar, it can stand a good heat, but does not like so humid an atmosphere as many other tropical plants. About 65° will generally be found sufficient after it has started growing in the spring. By midsummer the young plants may receive another potting, and again be cut back to make sure of having a good foundation for the following year. About the end of October, begin to withhold water from the roots, and cease syringing, which must be attended to during the period of active growth. Reduce the temperature to 55° to 60° during the night and give only enough water to keep the leaves from shriveling. As the sun gets higher in March, they will show signs of activity and the weak wood may be all cut back, and the plants repotted in a good strong loam with ample drainage. If not wanted for a specimen plant, stephanotis may be planted out on a well-drained bench and trained to wires over the roof. It is astonishing the amount of space a single plant will cover in course of time. For specimen plants, the shoots should be trained to strings until they set flowers, when they may be trained on a trellis in any shape desired. They will do

in the same size of pot for many years, if fed during their growing period as advised for ixoras. Mealy-bug and scale are sure to locate on stephanotis, but during the winter they may be treated to fumigations with hydrocyanic gas, as already advised for other plants, and if syringed well when out of flower, will be easily held in check. (Geo. F. Stewart.)

floribunda, Brongn. Fig. 3690. Glabrous, 8–15 ft.: lvs. elliptic, with a short point, thick and shining green, entire: fls. 1–2 in. long, of waxy consistency, white or cream-color, very fragrant, in many umbels, the calyx one-fourth or less the length of the corolla-tube: fr. 3–4 in. long, ellipsoid, glabrous, fleshy, containing melon-like seeds which are provided with a tuft of hair. Madagascar. B.M. 4058. G. 6:29, 291; 10:468; 13:622; 25:144; 37:397. Gn. 21, p. 441 (showing a pygmy plant blooming in a small pot and not climbing); 46, p. 208; 55, p. 150; 73, p. 211. G.C. II. 14:169 (a dwarf variety, the Elveston); 24:817; 25:137; III. 17:50. R.H. 1874, p. 368; 1885, pp. 438, 439. H.U. 1, p. 72. J.H. III. 50:165.

S. Thouarsii, Brongn., from Madagascar, appears to be the only other species in cult., but it is not in the American trade. It has obovate lvs., fls. in 3's, and sepals about one-third the length of the corolla-tube.

L. H. B.

STERCULIA (*Sterculius* of Roman mythology, from *stercus*, manure; applied to these plants because of the odor of the leaves and fruits of some species). *Sterculiaceæ*. Trees grown in the greenhouse, but also outdoors in the South.

Leaves undivided, lobed or digitate: infl. paniculate or rarely racemose, frequently axillary, with the terminal fls. commonly feminine and earlier: fls. unisexual or polygamous; calyx 5-cleft or 5-parted, rarely 4-merous, often colored; petals none; stamens united in a column which bears a head of 10–15 sessile anthers; pistil of as many carpels as calyx-lobes and opposite them, each carpel 2- to many-ovuled, the stigmas free and radiating: fr. follicular, each carpel distinct and either woody or membranaceous and sometimes opening and spreading into a lf.-like body long before maturity (Fig. 3691); seeds 1 to many, sometimes arillate or winged, sometimes hairy.—About 100 species, natives of the warmer regions of the world, most abundant in Asia. Sterculias have very various foliage, the lvs. of different species being simple, palmately lobed or digitate. The fls. are mostly in panicles or large clusters, sometimes large and showy, varying from greenish to dull red and scarlet. The species are grown mostly for street and lawn trees. The kinds that are generally known in this country are *S. platanifolia*, *S. diversifolia*, and *S. acerifolia*, the last two known in Calif. as brachychitons. All are easily grown from seeds. By Bentham & Hooker, *Brachychiton* is merged in *Sterculia*; by Schumann in Engler & Prantl it is kept distinct. See *Brachychiton*.

INDEX.

<i>acerifolia</i> , 6.	<i>colorata</i> , 5.	<i>occidentalis</i> , 8.
<i>alata</i> , 7.	<i>diversifolia</i> , 8.	<i>platanifolia</i> , 1.
<i>apetala</i> , 3.	<i>fœtida</i> , 2.	<i>rupestris</i> , 9.
<i>Bidwillii</i> , 4.	<i>Gregorii</i> , 8.	<i>variegata</i> , 1.
<i>carthaginensis</i> , 3.		

KEY TO THE SPECIES.

- A. Carpels expanding before maturity into lf.-like bodies, exposing the seeds 1. *platanifolia*
- AA. Carpels not becoming lf.-like.
 - B. Lvs. all digitately compound 2. *fœtida*
 - BB. Lvs. entire or only lobed (sometimes compound on some branches of Nos. 8 and 9).

CVII. Effective shrubbery border.—Spireas in good form.

- C. Surfaces of blade, at least the lower, tomentose or pubescent.
 D. Fls. yellowish white. 3. *apetala*
 DD. Fls. red. 4. *Bidwillii*
 CC. Surfaces of blade glabrous.
 D. Calyx tubular, the tube much longer than the lobes. 5. *colorata*
 DD. Calyx broadly campanulate, deeply lobed.
 E. Fls. glabrous. 6. *acerifolia*
 EE. Fls. tomentose, at least outside.
 F. Follicles globose, about 5 in. diam. 7. *alata*
 FF. Follicles ovoid, 1-3 in. long.
 G. Lvs. ovate or ovate-lanceolate, sometimes more or less 3-, rarely 5-lobed or -parted. 8. *diversifolia*
 GG. Lvs. oblong-linear or lanceolate, sometimes 5-9-digitate, parted on some branches. 9. *rupestris*

1. *platanifolia*, Linn. f. (*Firmiana plantanifolia*, Schott & Endl.). JAPANESE VARNISH TREE. CHINESE PARASOL TREE. Fig. 3691. Strong-growing, smooth-barked, round-headed tree of medium size, with deciduous foliage: lvs. very large, glabrous, cordate-orbicular, palmately 3-5-lobed like maple lvs., the lobes sharp-pointed: fls. small, greenish, with reflexed calyx-lobes, in terminal panicles: carpels 4 or 5, bearing globular pea-like seeds.—Said to be native of China and Japan. Hemsley admits it to the Flora of China, and Sargent says in Forest Flora of Japan that it is one of the several Chinese or Korean trees grown in Japan. Benthams, in Flora Hongkongensis, says that it is native to China. Franchet and Savatier, in Enumeratio Plantarum Japonicarum, admit it as an indigenous Japanese species. Now a frequent tree from Ga. south. Hardy also at Washington, D. C. Excellent for lawns and shade. A peculiarity of this tree is that before maturing the frs. are filled with a brownish black fluid which when the pods burst is liberated. Var. *variegata*, Hort., has lvs. variegated with creamy white. Intro. into Calif.

2. *fœtida*, Linn. Tall, handsome tree, with all parts glabrous except the young foliage: lvs. crowded at the ends of the branchlets, of 5-11 elliptic, oblong or lanceolate, entire, pointed, thick lfts.: fls. large, dull red, in simple or branched racemes, appearing with the lvs.: fr. large and woody follicles, glabrous outside, often 3 in. or more in diam. and containing black seeds the size of a hazelnut. Trop. Afr. and Asia to Austral.—Grown in S. Fla. In its native countries the seeds are said to be roasted and eaten.

3. *apetala*, Karst. (*S. carthagenensis*, Cav. *Helicteres apetala*, Jacq.). Tree, about 40 ft. high: lvs. cordate-rounded, usually more than 1 ft. diam., 5-(-3-) lobed to the middle, glabrous above, velvety beneath, lobes elliptical, obtuse, or oblong: fls. yellowish white with purple spots, about $\frac{3}{4}$ in. across. Mex., Cent. Amer., and Colombia; intro. into Jamaica and Fla.

4. *Bidwillii*, Hook. (*Brachychiton Bidwillii*, Hook.). Shrub or tree, softly pubescent or tomentose all over: lvs. usually deeply 3-lobed, green, soft-villous on both sides, lobes acuminate: calyx narrow tubular-campanulate, 1-1 $\frac{1}{2}$ in. long, red. Austral. B.M. 5133.

5. *colorata*, Roxbg. Large tree, bark ashy: lvs. roundish, 5-9 x 5-12 in., glabrescent, palmately 3-9-lobed, lobes triangular, acuminate, base cordate; petiole 4-9 in. long: panicle terminal, many-flid.; pedicels covered with orange-red tomentum: calyx $\frac{3}{4}$ in. across, tubular, clavate, orange-downy outside, pilose within: follicles 2-3 in. long, stipitate, glabrous, membranous. India.—Intro. into Calif.

6. *acerifolia*, A. Cunn. (*Brachychiton acerifolium*, F. Muell.). BRACHYCHITON. FLAME TREE. Evergreen tree, reaching a height of 60 ft., glabrous: lvs. long-petioled, large, deeply 5-7-lobed, the lobes oblong-lanceolate to rhomboid, glabrous and shining: fls. brilliant scarlet, the calyx about $\frac{3}{4}$ in. long, in large, showy trusses: follicles large, glabrous, long-stalked. Austral.—A most showy tree when in bloom, and planted on streets and lawns in Calif. Thrives in either dry or fairly moist places. (See also page 538.)

7. *alata*, Roxbg. Large tree, the young parts yellow-pubescent, the bark ash-colored: lvs. large, cordate-ovate, acute, 7-nerved: fls. about 1 in. across, in few-flid. panicles shorter than the lvs., and which arise from the leafless axils, the calyx tomentose and the segms. linear-lanceolate: follicles 5 in. diam., globose, with wide-winged seeds. India.—Intro. into S. Fla.

8. *diversifolia*, Don (*Brachychiton populneum*, R. Br.). BRACHYCHITON. Tall tree, glabrous except the fls.: lvs. very various, mostly ovate to ovate-lanceolate in outline, often entire, sometimes variously 3-5-lobed on the same tree, all parts acuminate: fls. tomentose when young, bell-shaped, greenish red and white or yellowish white, in axillary panicles: follicles 1 $\frac{1}{2}$ -3 in. long, ovoid, glabrous, stalked. Austral.—Planted in Calif., and commoner than the last. (Page 538.)

Var. *occidentalis*, Benth. (*Brachychiton Grégorii*, F. Muell. *S. Grégorii*, Hort.). Lvs. deeply 3-lobed, the lobes narrow, sometimes with short lateral ones: fls. salmon-color; calyx smaller and more tomentose. W. Austral.—Offered in S. Calif.

9. *rupéstris*, Benth. (*Delabèchea rupéstris*, Lindl.). BOTTLE-TREE. Considerable tree: trunk often swelling out to a large size, contracted top and bottom: lvs. glabrous, either quite entire and oblong-linear or lanceolate, 3-6 in. long, or digitate, consisting of 5-9 linear-lanceolate, sessile lfts. often above 6 in. long: calyx about 4 lines long, campanulate, tomentose both inside and out: follicles ovoid, acuminate, about 1 in. long, on stalks longer than themselves. Austral.

S. acuminata, Beauv.—*Cola acuminata*.—*S. Russelliana*, Hort., is said to be an aralia-like plant with the main st. and petioles light green and the narrow divisions of the lf. very dark green. Offered in the trade but not known botanically.

F. TRACY HUBBARD.†

STEREOSPERMUM (Greek, hard seed). *Bignoniaceae*. About 12 species of tropical evergreen trees in Afr. and E. India, with handsome once- or twice-pinnate foliage and large bignonia-like fls., pale yellow or rose-colored to purple, in large and loose terminal panicles; calyx campanulate, 2-5-lobed or 5-toothed; corolla funnellform-campanulate, with round crisped or toothed lobes; stamens 4, included; disk cupulate: caps. terete or 4-angled, 2-valved; seeds in 2 rows, with the thick nutlets deeply impressed in the thick spongy septum. Only the following species seems to be in cult. *S. suaveolens*, DC. Tree, 30-60 ft.: lvs. simply pinnate, 12-18 in. long; lfts. 7-9, broadly elliptic, acuminate or acute, entire or serrulate, hairy while young, about 5 in. long: panicle many-flid., viscous-pubescent: calyx campanulate, with 3-5 short lobes; corolla 1 $\frac{1}{2}$ in. long, pale or dark purple, puberulous outside, with crenately crisped lobes: caps. 18 in. long. Ind'a.—Adapted for tropical or subtropical regions only and prop. by seeds or cuttings, also by air-layering.

S. sinicum, Hance=Radermachia sinica.

ALFRED REHDER.

3691. Mature follicles or fruits of *Sterculia platanifolia*, bearing seeds on the margins. ($\times \frac{1}{2}$)

STERIPHOMA (Greek, *foundation*, alluding to the large peduncle of the fruit). *Capparidaceæ*. Unarmed shrubs with the branches and infl. stellate-pubescent, grown in the warmhouse: lvs. long-petioled, with 1 ft. which is lanceolate, entire; the petiole thickened at the top: fls. showy, orange, in terminal racemes; the pedicels bent or curved down, 1-fld.; calyx cylindrical-campanulate, 2-4-lobed at the top; receptacle very short, expanded into a ring-like disk; petals 4, sessile; stamens 6; ovary ovate or oblong: berry globose or angulate, corticate, pulpy.—Four species, Trop. Amer.

paradoxum, Endl. (*S. cleomoides*, Spreng.). Leafy shrub, 4-10 ft. high: branches erect or ascending, slender: lvs. alternate, crowded toward the ends of the branches, 4-7 in. long, oblong or ovate-oblong; raceme terminal, dense-fld., 1-3 in. long: fls. abruptly deflexed from the apex of the orange-yellow pedicels; calyx bright orange, oblong-cylindric, irregularly split halfway down; petals linear-oblong, pale yellow: fr. said to be cylindrical. Venezuela. B.M. 5788. F.S. 6:564-565. *Gr.* 57, p. 242.

STERNBERGIA (named for Count Caspar Sternberg, a botanist and writer, 1761-1838). *Amaryllidaceæ*. Low-growing bulbous herbs, hardy and used for outdoor planting.

Leaves produced after or with the fl., strap-shaped or linear: scape short: fls. frequently solitary, rarely 2, bright yellow; perianth funnel-shaped, erect, tube short or rather long, lobes linear or lanceolate, erect-spreading; filaments filiform, free; ovary 3-celled: fr. fleshy, ovoid or oblong, scarcely dehiscent; seeds subglobose.—About a dozen species, E. Eu. to Asia Minor. The

3692. *Sternbergia lutea*. ($\times \frac{1}{6}$)

bulbs should be planted rather deeply, about 6 in. J. N. Gerard says of their culture in G.F. 10:158 that they require a rather heavy soil, in a somewhat dry sunny position where they will be well ripened in summer.

A. Fls. and lvs. appearing together.

B. Blooming in fall.

lutea, Ker-Gawl. (*Amaryllis lutea*, Linn.). *Fig.* 3692. Bulb about $1\frac{1}{2}$ in. through: lvs. 6-8 to a bulb, strap-shaped, becoming 1 ft. long: fls. yellow, 1-4 to a bulb; tube less than $\frac{1}{2}$ in. long; perianth-segms. about $1\frac{1}{2}$ in. long. *Medit.* region of Eu. and Asia. B.M. 290. *Gn.* 44, p. 365; 47, p. 114. *G.C.* II. 13:21. *J.H.* III. 45:227. *Var. major*, Hort., has fls. much larger than those of the type.

BB. Blooming in spring.

Fischeriana, Roem. Has the habit of *S. lutea*, but differs in season of bloom and stipitate ovary and caps. Wm. Watson says (G.F. 8:144) that the fls. are a brighter yellow and as large as the largest forms of *S. lutea*. Caucasus. B.M. 7441. *Gn.* W. 22:307; 24:131.

AA. Fls. and lvs. appearing at different seasons.

B. Lvs. linear: fls. small.

colchiciflora, Waldst. & Kit. Bulb about $\frac{1}{2}$ in. through: lvs. appearing in spring, 3-4 in. long: fls. yel-

low, in fall; segms. about 1 in. long by 2 lines broad. E. Eu., Asia Minor. B.R. 2008.

BB. Lvs. strap-shaped: fls. large.

macrantha, J. Gay. Bulb globose, $1\frac{1}{2}$ in. through, with a long neck: lvs. becoming 1 ft. long, nearly 1 in. wide, fully developed in June: fls. bright yellow, 3-5 in. across; segms. about 1 in. broad. Oct. Asia Minor. *G.C.* III. 23:97; 28:265. *Gn.* 47:114. B.M. 7459. *G.* 24:497; 25:297. *G.M.* 44:47. H.F.II. 3:248 (as *Oporanthus macranthus*, Hort.).—A handsome species.

F. W. BARCLAY.

STEUDNERA (bears the name of Steudner, a German botanist). *Araceæ*. About 5 or 6 perennial herbs of E. Asia, sometimes seen under glass in choice collections, requiring the treatment of other aroids. Plant with a mostly short ascending sheathed caudex, and ovate-oblong long-stalked peltate lvs.: spathe ovate-lanceolate, recurving above the middle and convolute at base, much surpassing the spadix: fls. imperfect, the female with a subglobose 1-loculed ovary and 2-5 short staminodia: fr. a many-seeded berry. **S. colocasiaefolia** Koch. St. short and fleshy: lvs. green above and paler beneath, the petiole often colored: spathe yellowish, purple or reddish inside; spadix whitish, erect, one-third as long as the spathe. **S. discolor**, Bull. (*S. colocasiaefolia* var. *discolor*, Hort.), has purple-blotched lvs., and spathe yellow on both surfaces but reddish at base. These plants are warmhouse subjects, grown for the foliage and interesting habit, as well as for the infl.

STEVENSÓNIA (named after one of the governors of Mauritius). *Palmaceæ*, tribe *Araceæ*. A monotypic genus of tropical palms from the Seychelles. Tall trees, spiny throughout or at length nearly smooth, with ringed caudex: lvs. terminal, spreading-recurved, the cuneate-obovate blade convex, bifid, oblique at the base, plicate-nerved, the margins split, segms. deeply cut, the midnerves and nerves prominent, scaly beneath; petiole plano-convex; sheath deeply split, scaly, spined; spadix erect; peduncle long, compressed at the base: branches thickish: spathes 2, the lower one persistent, prickly, the upper one smooth, woody, club-shaped, deciduous: fr. ellipsoidal, small, orange-colored. For cult., see *Palm*.

grandifolia, Duncan (*Phœnicophorium sechellarum*, Wendl.). Caudex 40-50 ft. high, very spiny when young, less so when old; petiole 9-18 in. long, pale green; blade cuneate-obovate, shortly bifid, about 6-7 ft. long and nearly as broad: spadix 3-6 ft. long, bearing many yellow fls. Seychelles. I.H. 12:433. B.M. 7277. *Gn.* 23, pp. 173, 320.—Probably not cult. in Amer. The name *Phœnicophorium* (THIEF-PALM) commemorates the alleged theft of one of the original plants from Kew by a gardener in 1857. *Phœnicophorium* is antedated by *Stevensonia*, although a nomen nudum.

JARED G. SMITH.

N. TAYLOR.†

STEVIA: for the *Stevia* of florists, see *Piqueria*. True *Stevias* are described in horticultural literature, but it is not known that any of them are now in the American trade.

STEWARTIA (in honor of John Stuart, Earl of Bute, a patron of botany; 1713-1792). Sometimes spelled *Stuártia*. *Ternstræmiaceæ*. Ornamental woody plants chiefly grown for their large and showy flowers.

Deciduous shrubs or trees with smooth flaky bark: lvs. alternate, short-petioled, serrate: fls. axillary or subterminal, short-stalked, with 1 or 2 bracts below the calyx; sepals and petals 5 or sometimes 6, the latter obovate to almost orbicular, usually concave, with crenulate margin, connate at the base with each other and with the numerous stamens; styles 5, distinct or

connate; fr. a woody, usually hirsute caps., loculicidally dehiscent into 5 valves; seeds 1-4 in each locule, compressed, usually narrowly winged.—Six species in E. N. Amer. and E. Asia.

The stewartias are very desirable ornamental plants, with handsome bright green, rather large foliage which turns deep vinous red or orange and scarlet in fall; they are very attractive in midsummer with their white cup-shaped flowers, which are in size hardly surpassed by any others of our hardier shrubs. *S. pentagyna* and *S. Pseudo-Camellia* are hardy as far north as Massachusetts, while *S. Malachodendron* is tender north of Washington, D. C. They thrive best in deep, rich, moderately moist and porous soil, preferring a mixture of peat and loam, and, at least in more northern regions, a warm, sunny position. Propagation is by seeds sown soon after maturity and by layers; also by cuttings of half-ripened or almost ripened wood in late summer under glass.

A. Styles united; petals always 5.

B. Stamens purple, spreading; caps. subglobose.

Malachodéndron, Linn. (*S. virginica*, Cav.). Shrub, 6-12 ft. high: lvs. oval to oval-oblong, acute at both ends, serrulate, light green, pubescent beneath, $2\frac{1}{2}$ -4 in. long: fls. 3-4 in. across, with obovate spreading petals: seeds wingless, shining. May, June (July and Aug. in the N.). Va. and Ark. to Fla. and La. Gn. 14:136; 18, p. 628; 34, p. 280. G.C. II. 8:433; III. 42:32; 44:132. F.S.R. 1, p. 71; 3, p. 264. G. 29:309. B.M. 8145. —This is one of the showiest species, but tender.

BB. Stamens with whitish filaments, incurved: caps. ovate, pointed.

C. Bracts beneath the calyx large and lf.-like.

sinénsis, Rehd. & Wilson. Shrub or tree, to 30 ft.: lvs. oblong-elliptic to elliptic-obovate, acuminate, serrulate, glabrous or sparingly pubescent beneath, 2-4 in. long: fls. with large serrulate or entire bracts at the

base, white, 2 in. across; stamens connate at the base, pubescent: fr. subglobose, pointed, $\frac{3}{4}$ in. across. Cent China.

monadélpha, Sieb. & Zucc. Shrub or small tree: lvs. oval to oval-oblong, acute at both ends, remotely serrulate, slightly pubescent beneath, light green, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in.

3694. *Stewartia pentagyna*. ($\times\frac{1}{2}$)

long: fls. white, $1\frac{1}{2}$ in. across, with flat, spreading, obovate petals; stamens connate at the base; anthers violet; fr. about $\frac{1}{2}$ in. across. Japan. S.Z. 1:96.—This is the least desirable species and probably as tender as the preceding; it is doubtful whether it is in cult. Plants intro. under this name seen by the writer proved to be *S. Pseudo-Camellia*. Also the closely allied *S. serrata*, Maxim., differing in its glabrous lvs. and larger fls. with serrate sepals and distinct stamens is apparently not yet intro.

CC. Bracts small, shorter than calyx.

Pseudo-Camellia, Maxim. (*S. grandiflora*, Briot. *S. japonica* var. *grandiflora*, Hort.). Fig. 3693. Shrub, with upright branches, or tree attaining 50 ft. or more in Japan: trunk with smooth red bark, peeling off in larger thin flakes: lvs. elliptic to elliptic-lanceolate, acute at both ends, or often acuminate at the apex, thickish, bright green, glabrous or nearly so beneath, $1\frac{1}{2}$ -3 in. long: fls. hemispherical, 2-2 $\frac{1}{2}$ in. across; petals almost orbicular, concave, silky-pubescent outside; anthers orange-colored: seeds 2-4 in each cell, narrowly winged, dull. July, Aug. Japan. B.M. 7045. R.H. 1879:430. G.C. III. 4:187. Gn. 43:172. G.F. 9:35 (adapted in Fig. 3693). M.D.G. 1900:480. R.B. 28, p. 81. F.S.R. 3, p. 263. J.H. III. 54:57. S.I.F. 1:73.

AA. Styles 5, distinct: petals often 6.

pentágyina, L'Her. (*Malachodéndron ovatum*, Cav.). Fig. 3694. Shrub, 6-15 ft. high: lvs. ovate to oblong-ovate, acuminate, usually rounded at base, remotely serrate, sparingly pubescent and grayish green beneath, $2\frac{1}{2}$ -5 in. long: fls. cup-shaped, 2-3 in. across; petals obovate, with wavy crenulate margin; stamens white, with orange-yellow anthers: caps. ovate, pointed, sharply 5-angled; seeds narrowly winged. July, Aug. N. C. and Ga. to Tenn. and Fla. B.M. 3918. B.R. 1104. M.D.G. 1900:479. H.U. 3, p. 366. This shrub is handsomer than the preceding species and as hardy. Var. *grandiflora*, Bean. Fls. 4-4 $\frac{1}{2}$ in. across, with purple stamens. A very desirable variety which was found along with the yellow-stamened one in the woods of Ga.; the flowers are as beautiful as those of *S. Malachodendron*, and the plant is much hardier.

ALFRED REHDER.

3693. *Stewartia Pseudo-Camellia*. ($\times\frac{1}{2}$)

STIGMAPHYLLON (Greek, *stigma* and *leaf*; referring to the leaf-like appendages of the stigmas). Sometimes written *Stigmaphyllum*. *Malpighiaceæ*. Woody vines, grown in the warmhouse and also out-of-doors in the extreme South.

Leaves usually opposite, entire or denticulate, rarely lobed; petiole with 2 glands; stipules minute; fls. yellow, in umbel-like corymbs which are peduncled and axillary; calyx 5-parted, 8-glandular; petals clawed, unequal, glabrous, stamens 10, unequal, 6 perfect, 4 without anthers or deformed; ovary 3-celled, 3-lobed, dorsal lobe gibbous; samaræ 1-3, extended above into a wing.—About 55 species, Trop. Amer.

ciliatum, A. Juss. A tender woody twining vine: lvs. evergreen, smooth, opposite, cordate, ciliate; fls. bright yellow, large, in peduncled axillary clusters of 3-6. P.M. 15:77. Gn. 33:170.—Apparently the only species in the trade and possibly the handsomest of the genus. G. W. Oliver says that *S. ciliatum* is one of the best medium-sized vines for outdoor trellis-work. For pot culture it is of little service and thrives in the greenhouse only when planted out. Sept. is the best month for prop. On outdoor plants much of the wood is useless for this purpose, being thin and soft. Choose the wood made early in the season; a heel or joint is not necessary; root in bottom heat and carry through the winter in the greenhouse as small plants. It is said that in S. Calif. it must have shade, protection from dry or hot winds, and an open soil. Under the right conditions it flowers admirably.

littorale, A. Juss. A tall leafy climber: lvs. opposite and alternate, long-petioled, 2-5 in. long, varying in shape; fls. yellow, in profusion, borne on pedicels $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long; peduncles axillary, solitary; corymbs terminal, simple or compound; corolla 1 in. diam. Autumn. Argentina. B.M. 6623.

F. TRACY HUBBARD.†

STILLINGIA (for Dr. Benj. Stillingfleet, an English botanist of the eighteenth century). *Euphorbiaceæ*. Shrubs or herbs, chiefly of the American tropics, one rarely cultivated and used in medicine.

Glabrous, juice milky: lvs. alternate, simple, short-petioled to sessile, the petiole and bracts biglandulose; fls. in terminal spikes, monœcious, apetalous, the staminate above with the 2-3-lobed calyx imbricate, stamens 2-3, filaments free; the pistillate few, at the base of the spike; ovary 2-3-celled, 1 ovule in each cell; base of the caps. persistent as a 3-pointed piece; seeds usually carunculate.—About 25 species. Related to *Sapium* and *Hura*. The root of *S. sylvatica* is used in medicine. The plant is occasionally grown and will

stand temperatures at least to -10° F. It is readily grown from seeds but is not easily transplanted.

sylvatica, Linn. **QUEEN'S DELIGHT. QUEEN'S-ROOT. YAW-ROOT.** Root perennial, woody; sts. clustered, herbaceous, 1-3 ft. high, with an umbel-like top; lvs. lanceolate to oval or oblong, glandular, crenulate to obtusely serrate, acute or obtuse; spikes 2-3 in. long; fls. small, yellow. Spring to fall. Va. to Texas.

S. sebiferum = *Sapium sebiferum*. J. B. S. NORTON.

STIPA (Greek, *stipe*, tow, in allusion to the plumose awns of some of the species). *Gramineæ*. Perennial grasses with narrow involute lvs. and usually loose panicles: spikelets 1-fl.; glumes membranaceous, longer than the indurated lemma; lemma with a sharp hairy callus below and a stout persistent twisted awn above, falling from the glumes at maturity.—A large genus of about 100 species, throughout the world except the colder parts. Particularly characteristic of the plains, savannas, and steppes. The long-awned, sharp-pointed frs. of some species are troublesome or even dangerous to stock, especially sheep, on account of their tendency to work through the skin and into the vital organs. The species here mentioned are cult. for ornament, including the making of dry bouquets.

A. Awns and pedicels not plumose.

B. Fr. or mature lemma, excluding the long awn, $\frac{1}{2}$ -1 in. long.

capillata, Linn. Similar to *S. sparteæ*: fls. more numerous but smaller in every way; lemma about $\frac{1}{2}$ in. long; lower part of awn only minutely pubescent, the upper or bent portion sinuous. Plains, Eu.

sparteæ, Trin. PORCUPINE-GRASS. Culms 2-3 ft., in bunches: panicles contracted; glumes broad, nerved, about 1 $\frac{1}{2}$ in., tapering to a slender point; lemma nearly 1 in.; awn usually about 6 in. long, the lower half erect, pubescent but not plumose, strongly twisted, the upper half bent to one side, rough. Ill. to Calif. Dept. Agric., Div. Agrost. 20:62.

BB. Fr. or mature lemma, excluding the short awn, less than $\frac{1}{4}$ in. long.

arundinacea, Benth. (*Apèra arundinacea*, Hook.). Culms 2-5 ft.: panicles open, large, nodding; spikelets minute, 1 $\frac{1}{2}$ lines long, the awn about $\frac{1}{2}$ in. long. New Zeal. Hook. Fl. New Zeal., pl. 67. Exaggerated figure shown in G.C. III. 22:283.

splendens, Trin. (*Lasiagròstis splendens*, Kunth). Culms 3-6 ft.: panicles rather dense, about 1 ft. long, nodding; spikelets numerous, small, the glumes less than $\frac{1}{2}$ in., pearly and shining, tinged with purple at the base; lemma $\frac{3}{8}$ in., villous, the awn $\frac{1}{4}$ - $\frac{1}{2}$ in. Steppes of W. Asia.

3695. *Stipa elegantissima*. ($\times \frac{1}{2}$)

3696. *Stipa pennata*. ($\times \frac{1}{2}$)

AA. Awns or pedicels plumose.

B. The pedicels plumose.

elegantissima, Labill. Fig. 3695. Culms 2-3 ft., erect from a horizontal rhizome: lvs. narrow and erect: panicle very loose, 6-8 in. long, the capillary panicle branches and pedicels plumose; spikelets 4-6 lines long; awn $1\frac{1}{4}$ in. long. Austral.—Thrives in sandy soil.

BB. The awns plumose.

pennata, Linn. FEATHER-GRASS. Fig. 3696. Culms 2-3 ft., in bunches: glumes narrowed into awns an inch or more long; lemma $\frac{1}{2}$ in. or more long; awn about a foot long, the lower portion smooth and twisted, the upper very plumose, giving the panicle a feathery ornamental appearance. Sometimes erroneously called *S. gigantea*. Steppes of Eu. and Siberia. Gn. 9, p. 199. V. 3:247. R.H. 1890, p. 489.

tenacissima, Linn. ESPARTO-GRASS. Culms 2-3 ft., in bunches: lvs. narrow, smooth, cylindrical, elongated: panicles contracted; awn 1-2 in., plumose below the bend. Spain and N. Afr.—The lvs. furnish fiber from which are made ropes, mats, paper, and the like. In Afr. it is called halfa or alfa. A. S. HITCHCOCK.

STIZOLÒBIUM (name refers to the stinging pods). *Leguminosæ*. VELVET BEAN. Some of the species are grown as ornamental vines in warm countries, as the growth is very strong, but the genus is valuable mostly for its forage species and therefore does not demand extended treatment here.

These plants are allied to *Glycine*, which includes the soybean. The lvs. are large and 3-foliolate: fls. in axillary clusters, long or oblong, large, dark purple (sometimes white or yellowish) but turning black when dried, the corolla much longer than the narrow-lobed calyx; the keel long, boat-shaped and usually twice or thrice longer than the obtuse standard and also longer than the wings; stamens diadelphous (9 and 1) the anthers not uniform in kind: pod often hairy, bristly or pubescent, containing pea-like seeds.—Species perhaps a dozen, tropics of Old World. The genus *Stizolobium* was formerly included under *Mucuna*, but is now distinguished from that genus (which see, p. 2074, Vol. IV) by its seed and other characters. In *Stizolobium* the seeds are nearly spherical, or flattened-oval in shape, with the hilum covering often less than one-sixth of its circumference and never more than one-fourth, while in *Mucuna* the seeds are nearly circular in outline, flattened, and with the hilum extending at least three-fourths of its circumference. In germination *Mucuna* has alternate scale-like lvs., while *Stizolobium* has petioled, trifoliate lvs. with cordate flts. *Mucuna* is perennial, while *Stizolobium* is strictly annual. Such species of *Stizolobium* as are cult. for forage have pods which are nearly smooth, or are covered by a dense velvety pubescence; but there are a number of other species, notably *S. pruriens*, grown in the tropics, in which the pods have a dense covering of bristly stinging hairs, and are known under the common name of "cowage" or "cowitch."

The principal economic use of the velvet beans or stizolobiums is as a winter pasture crop in the southern states. They are commonly planted with corn, the stalks of which give the necessary support, without which they produce few seeds. Some cultivators plant two rows of corn and then one row of the beans, while

others plant the beans in alternate hills with the corn; the former method gives more corn to the acre, while the latter yields the heavier crops of beans. The crop is seldom cut for hay, as the vines are too long and tangled to be handled easily, but is left in the field until it is killed by frost, and is then grazed, as the vines, leaves, and seeds may remain on the ground a long time without injury from frost or rain. There are many varieties of this bean, some of which mature in about one hundred days from planting, while others fail to ripen without ten to eleven months free of frost. Some varieties produce profitable crops as far north as Tennessee, while others often fail to mature even in

southern Florida. Among the many kinds now cultivated in the United States the best known is the Florida velvet bean (*S. Deeringianum*, Bort). This is of unknown origin, but it has been cultivated as an ornamental vine in Florida many years. About 1890 its value as a forage plant attracted attention,

3697 *Stizolobium pruriens*, or cowitch. Flower-cluster usually longer and more tapering. ($\times$ about $\frac{1}{4}$)

and thousands of acres are now grown for feeding cattle and hogs. This species makes a wonderful growth, producing vines 60 to 100 feet in length, and bearing clusters of large purple pea-shaped flowers which are followed by pods 2 to 3 inches in length containing four to six nearly spherical seeds. In recent years several sports or varieties have been developed, which mature seed in 110 to 130 days from planting, and are now cultivated largely in the region from Florida northward to northern Georgia and Tennessee. Among the more common of the recently introduced kinds are the Lyon velvet bean (*S. niveum*, Kuntze) which bears racemes fully 3 feet in length with white flowers; the Chinese, which is similar but has shorter racemes and matures much earlier; the Black (*S. capitatum*, Kuntze), which has very long racemes with purple flowers, and late-ripening pods covered with a velvety pubescence; and the Yokohama (*S. Hassjoo*, Piper & Tracy), which matures within three to four months from planting. In addition to these there are numberless crosses and hybrids. As all the species are natives

of tropical or semi-tropical regions they require a long season without frost for their successful cultivation. For botanical and other accounts, see Bulletins Nos. 141 and 179, Bureau of Plant Industry, United States Department of Agriculture; also Belling on inheritance problems in crossing stizolobiums, Report of Florida Experiment Station for 1914.

The varieties mostly grown for ornament are the Lyon, with flowers in racemes often 3 feet in length; the Chinese, which is very similar to the Lyon but has shorter racemes and blooms much earlier; and varieties of *S. chlorospermum*, Piper & Tracy, with flowers light purple. All of these have pods 5 to 6 inches in length, f-shaped (the ends curved in opposite directions), somewhat brown- or gray-bristly. The most common species in this country is the Florida Speckled, *S. Deeringianum*, Bort. (Fig. 3697), which has been grown in Florida many years, and has been commonly known as "the vine." This seldom matured much seed north of central Florida, but in recent years several varieties have been developed which mature as far north as Tennessee. The pods of this species are usually less than 3 inches long, and are covered with a black velvety pubescence. All are annual climbers, growing to a great length. The branches are somewhat appressed-hairy, the leaves more or less silky beneath, leaflets ovate, or the lateral ones rhombic-ovate, obtuse but apiculate.

The cow-itch or cowage, *S. pruriens*, Medic. (*Dolichos pruriens*, Linn. *D. multiflorus*, Hort. *Mucuna pruriens*, DC.), is apparently the oldest species known, and has become naturalized in the West Indies, but is not grown in the United States. The pods of this species are red or reddish black in color, nearly straight, and 4 to 5 inches in length. They are very bristly-hairy, the bristles are easily dislodged by a touch and are extremely irritating to the skin, often producing troublesome blisters. In the West Indies a decoction of these hairs is often used as a remedy for intestinal worms.

Only varieties with a minimum growth of these stinging hairs are ever cultivated for either ornament or for forage.

It is an interesting fact that when any two distinct forms, both having relatively smooth pods, are crossed, the first generation always produces forms heavily covered with stinging hairs, although the second generation usually shows a large percentage of nearly smooth pods. This seems a strong indication that *S. pruriens* is the original type of the genus. Cattle

have been fed successfully on the meal made of the beans ground in the pod, but persons have been made sick by eating the green cooked beans, and chickens have been killed by both raw and cooked beans. Because of its vigorous growth, the velvet bean promises well as a soil-renovator,

as the cowpea does, although it can not be grown so far north as that plant. It is a good ornamental plant, growing 10 to 20 feet high when supplied with support. The handsome globular beans ($\frac{1}{8}$ to $\frac{1}{2}$ inch diameter.) have marking which suggests the castor bean.

S. M. TRACY.

STOBÆA (named for D. Stobæus, a Swedish patron of Linnaeus). *Compósitæ*. Somewhat shrubby plants or herbs commonly with aspect of thistles as to the foliage.

Leaves usually decurrent, dentate, pinnatifid or pinnatisect, lobes dentate and spiny: heads small to large, solitary or somewhat corymbose; rays usually yellow.—About 70 species. Now considered to be only a section of the genus *Berkheya*, and so named below.

B. membranifolia, Hubb. (*Stobæa membranifolia*, DC.). St. herbaceous, erect, cobwebby above: lvs. thin membranaceous, glabrous above, white-tomentose beneath; radical long-petioled, bordered with slender spines, oblong or elliptical, sinuate; cauline more copiously woolly beneath, more or less sinuous or pinnatifid, decurrent in ciliate-spinose sinuous st.-wings: heads solitary: fls. pale yellow. July, Aug. S. Afr.

B. purpurea, Benth. & Hook. (*Stobæa purpurea*, DC.). A half-hardy, probably biennial plant 2-3 ft. high: lower lvs. about 1 ft. long, irregularly lobed, spiny on the margins, cottony beneath, dark green above: st.-lvs. smaller, long-decurrent: fl.-heads 3 in. across, purple to white, resembling a single dahlia. G.C. 1872: 1261.—To be recommended for growing with half-hardy alpine. It can be wintered in a coldframe. Prop. by seed and division.

B. Rádula, Hubb. (*Stobæa Rádula*, Harv.). St. herbaceous, erect, angle-furrowed: radical lvs. obovate-oblong, obtuse, tapering to the base, some somewhat petioled, roughly setose at first then scabrous with hard points above, white-woolly beneath; cauline lvs. small, narrow-oblong or linear, very spiny, decurrent in long, narrow, very spinose st.-wings: infl. racemose-corymbose; heads short-radiate. S. Afr.

F. TRACY HUBBARD.

STOCKS. Popular florists' flowers, single and double, white, bluish, pink, purple, yellowish, valuable for cut-flowers (Fig. 3698). They are divided into two groups, summer and winter stocks. The former are annuals and therefore bloom the first summer; the latter are biennials and bloom the second year, or, if sown very early, late in the fall or the winter of the first year. Fall or intermediate stocks are between these two groups; they bloom profusely in the autumn. See *Matthiola*; also *Cheiranthus* for the closely related wall-flower (also *Wallflower*). Virginian stock is a very different plant and is not a regular florists' flower; it is grown for its small fragrant single fls.; see *Malcomia*.

Florists now frequently grow stocks in benches instead of carrying them through as potted plants. They are in considerable demand for Memorial Day. After the early bedding plants are removed to the frames, the benches are filled with soil and the plants that have been growing in pots since the seed was sown in December are then planted in them. Stocks may also follow chrysanthemums, the seed having been sown in August.

The seed of the summer stocks, or, as they are commonly called, "ten-weeks' stocks," is sown from the end of February until April, mostly in a lukewarm hot-bed, which must be sunny and well aired. Good clean garden soil, well mixed with sand and free of manure, is proper soil in which to sow the seed. The seed will germinate in six to ten days, the light-seeded sorts germinating more quickly than the dark-seeded kinds. Air must be admitted as soon as the seeds have sprouted, very much in warm weather and less when the weather is raw, until finally the sash may be entirely removed during the day. If the seedlings need water it should be given in the morning, so that they are dry at night. If

3698. Double stock.—*Matthiola incana* var. *annua*. ($\times \frac{1}{2}$)

the sun is hot the seedlings must be shaded. If the seed is to be raised from pot-grown plants a good well-manured, sandy garden soil should be used which contains an admixture of well-rotted sod or the soil taken from river-bottoms. The pots are about 6 inches high, with a diameter of 7 inches. When they show their fourth leaf the seedlings are planted firmly into these pots with a dibber, pots being well filled with the above soil; care should be taken that the roots are inserted vertically. From six to eight plants are put into such a pot. These pots are then placed on sunny stages, usually protected by tilt-roofs. The development of the plants depends now principally on careful watering, which is done mostly with watering-pots and at the beginning with a fine spray attached to the spout of the pot. After a crust has formed on the top of the soil, the spray is discontinued and the pots are watered with the pipe of the can. This watering is done at night during warm weather and in the morning when the weather is cold. Very little watering is necessary in continuously cloudy or rainy weather. The watering of the stocks is the most particular and important part in the cultivation in pots, for if due care is not exercised a white maggot will make its appearance while the plants are in bud and destroy the roots. The common flea-beetle is another of the enemies of stocks; this often appears in large numbers and eats the leaves of the young plants. Frequent syringing with water is the only remedy found so far against these pests when they infest stocks.—After the plants have been in bloom for some time the double-flowering specimens are cut out and the watering is continued carefully until the seed-pods which form in the single plants show indications of ripening, which is in October. The plants are then pulled and tied in bundles, which are hung up in dry sheds until the middle or the latter part of November and December, in which time the seed fully matures in the pods. Now comes the most important part of seed-saving of stocks. The bundles of plants are taken down, the roots and part of the stems cut off, and the stalks are taken in hand by expert gardeners who sort them for common seed and also for the seed-stock. The pods indicate by their shape, size, and form whether the seeds contained therein will produce a high percentage of double flowers the following year, and the selection is made with care. The seed that goes on the market can be vastly improved by the removal of "wild" pods, which contain seeds that produce nothing but single flowers. The seeds are removed by hand from the pods, mostly by women and children.

CARL CROPP.

STOKESIA (Jonathan Stokes, M.D., 1755–1831, English botanist). *Compositæ*. STOKES' ASTER is one of the choicest and most distinct of American hardy perennial herbs, although little planted.

Heads many-fl'd.; marginal fls. much larger, deeply 5-cut; involucre subglobose; outer leafy, the inner with foliaceous, pectinately spinulose-ciliate, spreading appendages; receptacle fleshy, flat, and naked; achene 3–4-angled, smooth; pappus of 4–5 thread-like, deciduous scales. The species is a blue-fl'd. plant about a foot high which at first glance has points in common with China asters, centaureas, and chicory. The heads are 3 or 4 in. across in cult. The marginal row of fls. is composed of about 15 ray-like corollas, which have a very short tube at the base and are much broadened at the apex and cut into 5 long, narrow strips.

The plant is hardy as far north as Rochester, New York, and Boston, Massachusetts. Probably many persons have been deterred from trying it because it is native to South Carolina and Georgia, and because it is considered a greenhouse subject in some standard works on gardening. The fact that it is found wild in wet pine-barrens is also deceptive, for the roots, as Woolson and Keller testify, will decay if water stands on the soil in winter. Moreover, the plant has been praised by

Meehan for its drought-resisting qualities. Stokes' aster should be planted in a well-drained sandy loam, not in cold and heavy clay. It blooms from August until hard frost. According to Chapman, the heads of wild specimens are only an inch across, but the size of heads in cultivated plants is stated by many horticultural experts to be 3 to 4 inches across. The heads are

3699 *Stokesia laevis*. ($\times \frac{1}{2}$)

frequently used for cut-flowers. In the wild the heads are few in a cluster or solitary; in cultivation a good branch sometimes bears as many as nine heads. No double form seems to have appeared but a white-flowered form is now on the market.

laevis, Hill (*S. cyanea*, L'Her.). Fig. 3699. Much-branched, hardy perennial herb, 1–2 ft. high; branches often purplish, sometimes hairy when young; lvs. lanceolate; radical ones entire, tapering at the base into long, flattened stalks; cauline lvs. gradually becoming sessile, the uppermost with a few teeth near the base and half-clasping; fls. blue or purplish blue, 3–4 in. across. Aug.–Oct. S. C., Ga., to La. B.M. 4966. Mn. 5, p. 214. A.G. 25:117. F.E. 16:650. G.M. 49:563. R.H. 1863:211. Var. *alba*, Hort., has white fls. Var. *præcox*, Hort., is a lavender-fl'd. sort.

WILHELM MILLER.

STONECROP: *Sedum*.

STORAGE and refrigeration of fruits and vegetables. The storage house has become a very important adjunct to fruit-growing. In fact, fruit-growing would not be possible in present-day large-scale practice without storage, or some means to preserve the fruit from deterioration. Without some way to hold fruits in sound condition during the time required to transport them from the place of production, the development of the large fruit industries of the West and South would be impossible. The two most important factors underlying the success of modern fruit-growing are the discovery of methods of controlling insects and diseases and the application of refrigeration to the transportation and storage of the crops. The time required to transport fruit crops to the centers of consumption varies from a few hours to ten days, and in some cases two or three weeks are required, especially when the fruit is exported to foreign countries. Under these conditions, the trip to market really becomes a period

of storage and the application of storage principles is as important as transportation principles. The object of refrigeration in the transportation of fruits involves only the holding of the fruit in sound condition long enough to reach the consumer. Storage, on the other hand, includes the holding of the product for a long or short period, thereby lengthening the season of marketing as well as increasing the territory over which it may be distributed. The lengthening of the season of marketing or period during which the product may be sold, is very essential when the production of fruit crops has reached a point greater than can be consumed during the normal season. This is aside from the general advantage of having a product out of season, for which many consumers are willing to pay fancy prices. The conservation of the surplus crops through storage enables the equalization of the selling or marketing season, giving the consumer the advantage of obtaining supplies during a longer period, and giving the producer a chance to market larger crops at profitable prices. The application of storage to the apple industry has resulted in making this fruit an all-the-year-round staple food, as supplies are easily held from one season to the next. The advantages of this to both consumer and producer are manifest. If all the apples produced had to go into consumption during the normal season of this fruit, there would be alternate periods of plenty and scarcity. The same is true, although to a less extent, of other fruit crops, such as pears, grapes, lemons, and oranges. Many of the vegetable crops are likewise held successfully in storage for longer marketing periods than their normal seasons. Potatoes, celery, cabbage, onions, and even lettuce and cauliflower are successfully stored for varying periods.

Storage also finds application in other horticultural industries. The nurserymen are enabled to hold their stocks of trees, plants, cions, or cuttings until the proper season of planting or propagation arrives. Bulbs, lily-of-the-valley crowns, and cut-flowers are also successfully held in cold or cool storage much longer than would otherwise be the case. All of these examples are mentioned to indicate the wide application of storage to horticultural industries.

There are several different methods of conserving or preserving food products. Among these methods may be mentioned curing, drying, salting, smoking, canning, use of chemical preservatives, and by refrigeration. Of these the last method is the only one by which the products are held in their original or "fresh" condition. All other methods involve a change in the character of the product. Cold-storage conservation aims to hold the product in such a condition that it may be used as fresh. If the storage does not accomplish this, it falls short of its principal object.

Two kinds or methods of storage are recognized at present: These are (1) cold storage, and (2) common storage, sometimes known as "dry storage." The objects of these two methods of storage and their accomplishment are the same. "Cold" storage is designated as artificially cooled storage, or the holding of the products in rooms or buildings which are artificially refrigerated, i. e., the cooling is effected by means of machinery or ice. "Common" storage is the term applied to storage without ice or mechanical refrigeration, the cooling effect being obtained from the natural low temperature of the outdoor air. The aim of common storage is "to conserve the natural cold" in buildings which are specially constructed and equipped with proper ventilating devices or openings. It is difficult to determine the exact reason for designating this type of storage as "dry" storage. Both cold and common storage must be dry, excessive moisture in either case being detrimental. A possible explanation of the use of the term "dry" in this connection is the fact that in the first cold-storage houses ice was the refrigerant with necessarily more or less dampness about the plant; while in

common storage, no ice is used ordinarily and consequently there is no dampness from this cause.

Contrary to general belief, the use of cold storage is not confined to modern civilization. Frank N. Meyer, Agricultural Explorer for the United States Department of Agriculture, reports the finding of the use of cold-storage methods applied to fruits in remote parts of China, wholly out of touch with modern civilization. Meyer states that the Chinese have practised cold-storage methods for centuries. They are able to hold grapes from one year to the next by storing them in deep cellars which are kept cold with baskets of broken ice placed among the baskets of fruit. He found also that the Chinese fruit merchants keep perishable fruits in large thick-walled earthen jars, in the bottom of which a layer of broken ice is kept and over this, in wicker baskets, the fruit is held. The jar is covered by a wooden felt-covered lid. It is a long step from these ancient Chinese ice-cooled cellars and jars to the modern mechanically refrigerated storage house, but it is certainly of interest to find that the ancients understood the fundamental principles of the conservation of foods through the reduction of their temperature.

There has been much discussion during the past few years regarding the application of storage (cold or refrigerated storage principally) to the conservation of foods. It seems unfortunate that the bulk of this discussion has taken a rather condemnatory stand. The dangers of the use of cold-stored food products have been over-emphasized. The present high cost of living has been at least partly ascribed to the supposed pernicious practice of "cornering" foodstuffs during their normal seasons at low prices, and holding them in storage to be sold at arbitrarily high prices. While there is no doubt that attempts have been made to corner foodstuffs in this way, experience shows that these attempts have been few and almost uniformly disastrous financial failures so far as the promoters were concerned. As will be shown later in this article, the holding of fruits or other foods in storage is rather expensive and not so simple as it seems to be at first sight. Not all products are uniformly suitable for storage and unless the greatest care is exercised both in selecting the product and preparing it for storage, serious losses from deterioration are certain.

Another unfortunate fallacy, that cold-stored products are necessarily inferior as such, has become widely prevalent, due to campaigns in newspapers and magazines with a view mainly of casting odium upon stored products. There can be no doubt that much poor cold-stored food materials have been sold. Deteriorated foods have frequently been foisted upon consumers. The fallacy lies in attributing the deterioration alone to cold storage. Such deterioration can usually be traced to the poor condition of the product at the time it was placed in storage, to improper methods of preparing the product for storage, or to attempts to hold it too long. The application of the low temperature is not detrimental unless the temperature is low enough to injure the product by freezing. No product can be improved through cold storage. If it is in poor condition when it is placed in storage, it will be in much poorer condition when it is withdrawn. If it is in good condition at the time it is stored, it will remain in first-class condition throughout its normal life, provided always that the storage plants or rooms have been properly operated.

Many fallacious arguments have been offered tending to prove that holding in cold storage is itself sufficient to render a given food product unwholesome. While unwholesome cold-stored products have at times been placed on the market, as admitted in the preceding paragraph, the condition of the goods was due to the three causes above enumerated and not alone to the application of refrigeration. The attempts to hold supplies which have deteriorated before they are placed in

storage are frequently responsible for untimely deterioration, and the practice should be discouraged; but so far as fruits and vegetables are concerned, it is perfectly safe to state that no injurious effects have ever followed the use of these cold-stored foods. The evidences of deterioration are plainly visible in fruits and vegetables and there are no hidden germs or ptomaines. No one is likely to be deceived into eating a deteriorated fruit or vegetable.

The agitation against cold-stored food products has resulted in a demand for legal regulation of the storage business. Several states have passed laws prescribing certain conditions which must be met. Attempts have been made to obtain federal regulation, and no doubt federal laws concerning the cold storage of foods will eventually be enacted. The state laws now in effect and the proposed federal legislation place arbitrary limits upon the time the products may be held; provision is also made regarding the marking of the products, and the inspection of the goods from time to time is provided. Legal regulation of this business is desirable and wise, but it is not wise to present arbitrary obstacles to the development of refrigeration. It is questionable whether the adoption of an arbitrary length of time for holding all products is wise or safe. Not only does the length of time vary for different classes of goods, but within the same class the condition of the product at the time it is placed in storage or its treatment previous to storage very materially influences the time the product may be held in wholesome condition. Thus, not all apples of a given variety may be held the same length of time. The length of the period of successful storage will depend upon the condition of the fruit, its stage of maturity, the care with which it has been handled, and also the promptness with which it has been cooled. The same principle holds true for all other fruit and vegetable products. It would seem, therefore, that some provision for the inspection of food products to determine their fitness for storage would be wise and would result in preventing many losses now sustained through the storage of unfit goods. So far, none of the laws passed or proposed makes this provision.

This argument is not offered to defend the cause of cold-storage warehousemen. They have not been entirely free from blame in the past. The possibilities and the advantages of cold storage should be fully appreciated by consumers and producers alike. The necessity for refrigeration in horticultural industries will undoubtedly become more and more urgent, and the use of this important adjunct to modern fruit-growing is bound to extend its scope and receive wider application in the future.

Cold storage is a modern economic necessity. Through this system of food conservation, the extension of markets and the territory over which different commodities may be distributed are very materially increased. In the use of cold storage or refrigeration, the first establishments depended on ice for the refrigerating medium. In the earliest plants natural ice was used. This was gathered or "harvested" during the winter and used during the spring and summer months. There is a very large quantity of natural ice used under modern conditions, but the manufacture of ice is increasing and the use of "artificial" ice is likewise extending, even in districts where natural ice may be obtained without difficulty.

Systems of refrigeration.

In modern cold-storage plants two systems of refrigeration are used: (1) ice refrigeration, and (2) mechanical refrigeration. There are several methods of applying each system. In the use of the first, ice alone may be the refrigerant, or a mixture of ice and salt may be used to obtain lower temperatures than are possible from ice alone. In the application of the ice-and-salt

refrigerant, several systems may be used, as will be explained later. The ice used may be manufactured or natural, depending on the relative cost.

In the mechanically refrigerated plant, the refrigeration is secured directly without first producing ice. It is apparent that the direct application of the refrigeration results in a very material saving in both time and energy. In this way, the cumbersome method of first manufacturing the ice and the consequent inconvenience in handling it are avoided.

There are two kinds or styles of cold-storage plants—the general warehouse, provided with cold-storage equipment for handling all classes of commodities; and the storage plant constructed specially for the storage of a particular class of commodities—fruit or dairy products for example. It is evident that the large general warehouse may have a very great advantage in economy of operation. The general warehouse handles a mixed business which often results in a more economical distribution of overhead operating expenses than is possible when the entire burden of expense must be borne by a single commodity or single class of commodities. It is easy to see that the greatest efficiency and economy of operation occur where practically the entire capacity of the plant can be utilized during the year. This is hardly feasible with fruits, with the possible exception of apples which are now held largely during the greater part of the year. But even in the case of apples, there cannot be a full use of the equipment continuously, as the withdrawals will be gradual throughout the season. Nevertheless, the construction and operation of cold-storage plants for apples or other fruits is constantly increasing. These plants may be owned by special corporations or may be built and operated by growers' organizations or by growers who have sufficient acreage to warrant the extra provision of storage facilities. In some instances the ownership or control of cold-storage facilities has rendered fruit-growers independent of buyers' or speculators' manipulations of prices or marketing facilities.

Mechanical refrigeration depends on the compression of a gas or vapor. The compression exerted heats and, in some instances, liquefies the gas. The heat is absorbed by means of cooling water, and when the gas is allowed to expand, an equal number of heat units is absorbed from the surrounding medium. This, briefly, is the general principle upon which depends the operation of refrigeration machines. The gases used may be air, ammonia, sulfur dioxide or carbon dioxide, commonly known as carbonic-acid gas. In the cases of air machines, the air is simply compressed under very heavy pressure and cooled by means of water. There is no liquefaction of the air attempted in the case of these machines. The advantages of the air-compressors are that they are comparatively easy to manipulate and there are no injurious effects in case of leakage from the compressed vapor. These machines are used to a great extent on shipboard, and in England to a much greater extent than in the United States. Improvements in the construction of air-compressing machines are resulting in their increased use. The disadvantage of the air-refrigerating machines is that they are relatively inefficient for low temperatures. There being no liquefaction of the gas, the advantage of the latent heat due to the change of state is absent, and consequently there is a loss of efficiency to the extent of the latent heat necessary, first, to change the gas to the liquid and then back from the liquid to the gaseous state.

In the machines which utilize a liquefiable gas, that is, a gas which may be liquefied at comparatively high temperatures, the latent heat due to the change of state adds greatly to the efficiency of the machines, and consequently, much lower temperatures can be secured for a given amount of power. One of the essential qualities of the gas which may be used for this purpose

is that it must be comparatively inexpensive and must be within the means of utilization by a comparatively simple apparatus. Ammonia, sulfur dioxide, and carbon dioxide are in general use in about the order named. Ammonia is the most common, and is in many respects the easiest to handle. It may be liquefied at a lower pressure and a higher temperature than either carbon dioxide or sulfur dioxide. Carbon dioxide is, therefore, somewhat less efficient to the extent that the high pressure requires more power, there is greater friction to overcome, and colder water is needed for condensation. These conditions are not always obtainable within ordinary means. Carbon dioxide has the advantage of being a non-irritating and non-poisonous gas. If leaks occur in the system, there is no great danger of serious injury either to the operators of the machinery or to the goods stored in the rooms. If leaks occur in the ammonia system or in the sulfur dioxide machines, there is very great danger of injury to the workmen about the plant and the food commodities exposed to these gases may be very seriously injured, even with a slight leakage. Nevertheless, the greater ease with which the ammonia machines can be manipulated is considered a sufficient advantage, and this type of machine is much the commonest now in use.

The system of operation of the refrigerating plant is comparatively simple although rather complicated machinery is required. It is not essential that the fruit-grower who contemplates the erection of a refrigerating plant be conversant with all of the complicated details. It is well, however, that he understand the principles upon which the machines are designed. For the erection and planning of a complete storage plant depending on refrigerating machinery, the services of a competent refrigeration engineer are essential. While it may be possible for a mechanically inclined fruit-grower to design and have erected a complete refrigerating plant, it must not be forgotten that slight errors in the calculation of the power required and the capacity of the machinery necessary to yield given results will frequently render the operation of the plant very much more expensive than need be, or the efficiency of the plant may be very seriously impaired. Refrigerating machinery is, of necessity, expensive; it is likewise delicate in many respects.

There are many styles and designs of refrigerating machines. All, however, are dependent upon the same general principles. There is, first of all, the motive power which may be either the gasoline or electric motor, or the steam engine, which furnishes the power to operate the compressor. The compressor exerts pressure on the gas, heating it to a rather high temperature. If the machine is operating with ammonia gas, the compression results in a dense hot vapor. From the compressor, this hot vapor passes to the condenser, which is a system of pipes arranged in such a way that streams of cooling water may be passed continuously around the pipes containing the hot gas. The absorption of the heat from the dense vapor condenses it into liquid ammonia. This liquid is ordinarily run into a receiver or reservoir, where it is kept for use as needed. From the receiver, the liquid ammonia is forced into what is known as expansion coils. These coils consist of series of pipes into which the liquid ammonia is allowed to enter. The liquid boils at a low temperature and changes from the liquid to the gaseous state, and in changing its state and expanding absorbs considerable heat from the surrounding medium; in this way the refrigeration is obtained. After expansion, the ammonia gas is passed back to the compressor where it is again compressed and afterwards liquefied, the same gas being used over and over again.

Instead of the compressor, the same effect can be obtained from what is known as the absorption system. This is a combination of a chemical and mechanical process. No compressor is used. Dense aqua-ammonia,

which is simply a strong solution of ammonia gas in water, is heated in a reservoir, and as the ammonia escapes from the solution, it is under heavy pressure and becomes a dense vapor. From this tank the gas is passed through condensing coils and liquefied, just as is done in the compression system. After liquefaction, it is allowed to expand in coils and the gas is then returned to a tank or a series of tanks known as absorbers. These absorbers contain cool water which readily absorbs or dissolves the ammonia gas. From the absorber, the solution is pumped into the heating tank, again heated, and the process repeated.

When one contemplates the installation of refrigerating machinery, one of the most important factors to consider is the supply of water needed for condensing. This is ordinarily of very much greater importance than is appreciated. Large quantities of water are needed unless the temperature of the water is very low. The higher the temperature of the water-supply, the larger the quantity needed. The same water may be used continuously if there is some means at hand to cool it after it has served to absorb the heat from the condensing ammonia. In large refrigerating plants this is taken care of by means of large racks or towers located in some exposed place. In these towers, the water is run through screens which break it into many fine streams, thus increasing the evaporation and cooling the water by the absorption of its heat. Unless some means is at hand to cool the water, a constant supply must be provided; otherwise, the efficiency of the machinery will be very greatly reduced. This point is of the utmost importance when refrigerating plants are to be located in fruit-growing districts. In fact, the practicability of operating the refrigerating plant successfully depends primarily on the presence of a sufficient supply of water for condensation.

Ice systems.

Refrigeration may be obtained from the use of ice alone. In this instance, however, only cool-storage effects can be obtained, except in winter and in climates where the outdoor temperature is low enough to offset the lack of refrigerating effects from the ice. The minimum temperature obtainable from ice is its melting point, which is just above 32° F. or, under the very best conditions, about 33° or 34°. Generally, ice-cooled chambers cannot be maintained below a temperature of 38° or 40° and these temperatures are obtainable only under the most favorable conditions. To obtain a low temperature from ice, the addition of salt is necessary. The mixing of salt with the ice lowers the melting-point and, consequently, the temperature is lowered, although the rapidity with which the ice is consumed is very greatly increased. When the mixture of ice and salt is used, the quantity of ice necessary for storage is much greater. A lower temperature is necessary to hold the storage chambers at 32° F. because of the heat leakage into the chambers through the walls.

There are two methods of obtaining refrigeration from ice and salt. One of these is the indirect method, known as the gravity-brine system, and the other is the direct circulation of air through the ice and salt mixture.

The gravity-brine system, the invention of Madison Cooper, acts as the reverse of a hot-water heating system. It depends on the principle of the greater density of a cold liquid, and its consequent downward flow when confined in a system of pipes. The system consists, first of all, of coils of pipes filled with a strong solution of calcium chloride brine. One end of the pipe system is contained in a tank which holds ice and salt. The cooling effect of the ice and salt results in greatly reducing the temperature and increasing the density of the brine. From these "primary" coils the brine is conducted into what is known as secondary coils which are placed in the rooms or chambers to be cooled.

The cold brine passes through the secondary coils, and, as it absorbs the heat from the rooms or chambers, its density is decreased and it flows upward and is returned to the top or primary coils, where it is cooled and the process repeated. Fig. 3700 is a diagram illustrating the principle upon which the Cooper gravity-brine system depends. At the top of the illustration the primary coils are shown and the methods of placing the pipe systems or coils is indicated.

The cooling effects secured from the Cooper brine system are indirect in that the refrigeration obtained from the ice-and-salt mixture is first exerted upon the brine solution and this solution is the means of carrying the refrigeration to the place where it is needed. There is an inevitable loss in the indirect method because of the loss of refrigeration in the conducting pipes.

In the second system of securing refrigeration from ice and salt, the air is passed directly through the mixture and, consequently, the refrigerating effect is obtained directly from the mixture. Experiments

drawings or instructions. A fan is used to draw the air through the ice-and-salt mixture and to force the refrigerated air into the storage chambers. Ducts are provided for the return of the air, and in this way the same air is used continuously.

There is another method of securing refrigeration from ice and salt which may be designated as the "tube system." In this system the mixture of ice and salt is contained in tubes located at the sides of the room. The tubes are filled with the mixture from the top and the refrigeration is obtained by the cooling of the air in contact with the tubes. The number of tubes necessary to cool a given quantity of goods depends upon the character, size, and insulation of the room. The tubes are constructed of galvanized iron and are about 8 or 10 inches in diameter. The tops of the tubes open above the storage room, so that the filling can be done without opening the room itself. A proper arrangement of pipes at the bottom to carry off the meltage is necessary, and in arranging for this meltage outlet, a proper trap must be provided in order to prevent the wastage of the cold air. This system has found considerable application in the Hudson River Valley of New York state, and is very effective for a short season of storage.

Systems of applying refrigeration.

Refrigeration may be defined as the cold obtained from a refrigerating medium or directly from mechanical appliances. The temperature-reducing properties of the ice-and-salt mixture and those of the liquid ammonia are the refrigerating qualities of these agencies. Refrigeration is ordinarily measured in terms of ice-melting capacity in a day of twenty-four hours. For example, a machine which is rated as yielding a capacity of ten tons a day is based upon the meltage of ten tons of ice in that time. Ordinarily, it is not the quantity of ice which can actually be produced by the machine, except when ice manufacture is the primary object.

There are three systems of applying the refrigeration secured by mechanical means: (a) direct expansion; (b) brine circulation; (c) air circulation.

In the direct-expansion system, the expansion pipes in which the gas is allowed to expand, and thereby produce the refrigeration, are located in the storage rooms. The claims for this system are that the work is direct; therefore there is no loss in conducting the refrigeration obtained from the pipe surface. The greatest objection to this system, especially with ammonia or sulfur dioxide plants, is the danger of leaks. Small leaks may allow a sufficient quantity of gas to escape to damage the goods stored in the rooms; there is also great danger to the workmen, which has already been referred to. The greatest care is necessary in constructing the direct-expansion system. With the perfection of mechanical devices for welding and fastening pipes, the danger from leaks has been reduced to a minimum, and there are many direct-expansion systems in operation in which no injuries have ever been recorded. One disadvantage is the fact that there is no reserve power except that which is contained in the liquid receivers. Should it be necessary to shut down the machinery for repairs for any considerable length of time, there would not be sufficient reserve to continue the refrigerating effects and the temperature of the storage rooms would be likely to rise to a considerable extent.

In the brine-circulation system, the expansion coils are surrounded by a non-congealable brine such as a solution of calcium chloride, which has a very low freezing-point. The brine is cooled in the pipes and this cold brine is circulated through coils in the rooms by means of pumps. In applying this method, there is, first, what is known as a brine-cooler in which the actual cooling of the brine takes place; the cold brine is then

3700. Diagram of Cooper gravity-brine system.

have shown that very low temperatures can be obtained by passing a current of air through an ice-and-salt mixture, the temperature depending on the proportion of salt used in the mixture. The higher the percentage of salt the lower the temperature obtainable. The device for obtaining refrigeration in this way is simple. It consists of a tank for holding the crushed ice and salt. At the bottom of this tank openings are provided through which a current of air can be forced. The particular working out of the design for obtaining refrigeration in this way has been accomplished by S. J. Dennis, of the United States Department of Agriculture. Dennis' apparatus has been used successfully in several plants on the Pacific coast, and owing to the fact that it was developed as a part of the Departmental investigations, its use by the citizens of the country is free. It is essentially an ice-and-salt tank of "magazine" type. As the ice is melted at the bottom the supply from above drops down. From 7 to 10 per cent salt has been found to yield satisfactory temperatures. The apparatus can be constructed by almost any ordinary mechanic who can follow detailed

collected in a brine tank of sufficient capacity to operate the plant for a considerable length of time. This really acts as a reservoir of cold, and from this reservoir the cold brine is circulated throughout the entire cold-storage plant, the temperature and quantity of the brine circulated being governed by the results desired.

The coils of pipes in the rooms are commonly referred to as the "piping." These coils or racks of pipes are the room's equipment for refrigeration, and the number of coils or length of piping depends upon the size of the room and the temperature desired. Low-temperature rooms or freezers have a large number of coils and a great length of pipes. Pre-cooling rooms should also have heavy piping and many pipes. The advantages of the brine-circulation system are that there is no danger from leakage of ammonia or other irritating gas. The statement is also made that there is a more uniform temperature, the flow of the brine being under constant and easy control. The temperature of the brine is also under definite control. Perhaps the greatest advantage is that the supply of cold brine acts as a reservoir of refrigeration and a reserve supply can be drawn upon in case of necessary shutting down of the machinery.

In placing the pipes in cold-storage chambers, it is important to have them located at the upper part of the room. Ordinarily, the dependence for the circulation of refrigeration throughout the room is on the natural circulation of the air within the room. The air in contact with the pipes is cooled and, being rendered more dense, flows to the floor, the warmer air from other parts of the room taking its place. In this way, a constant circulation throughout the room is maintained. It is easy to see, therefore, that the placing of the pipes in the upper part of the rooms is essential; otherwise, there is danger that the parts of the room above the pipes may be beyond the refrigerating effects. The air is, therefore, the medium of applying the refrigeration. It is due to convection currents that the transfer from the refrigerating pipes is effected, and it is very difficult to obtain a uniform cooling in all parts of the room unless the pipes are carefully placed.

In the air-circulation system of applying refrigeration, there is a forced air circulation. The air is forced through conduits or ducts by means of fans. In this system the expansion coils of pipes are in groups or batteries in what are known as bunker rooms, or more correctly, coil rooms. The refrigerating capacity of the plant is, therefore, concentrated in one place. In arranging the coil pipes, baffles are placed in such a way that the air passing through the coil rooms must come in contact with all of the pipes. If all of the pipe surfaces are not reached by the air, the full refrigerating effect of the plant is not obtained. The coils may be direct-expansion coils or brine-circulating coils, that is, have the brine circulating through them. The Cooper gravity-brine system may also be used. For this purpose, the secondary coils are located in coil rooms where the air to be cooled can be forced through.

In placing the fans for such a plant, the arrangement must be such that the air is drawn from the coil room and forced through ducts to the storage chambers. With this arrangement there is a constant pressure in the rooms which is preferable to the exhaustion of the air. Any leakage which occurs, therefore, is outward from the room instead of inward. Return ducts are provided which conduct the air back to the coil rooms, the same air being used continuously. Impurities from the storage rooms are absorbed by the air and deposited in the moisture which freezes on the cold pipes. The impurities, therefore, are very largely absorbed by the frost, and the circulation of the current of air through the coil rooms acts largely as a purifier of the air of the storage rooms. Some ventilation, however, is frequently desirable. The problem of ventilating a cold-storage

chamber is a difficult one and special appliances must be provided for this purpose. The outer air cannot be admitted directly into the storage chamber unless it is at the same temperature as the air of the storage room. In warm weather, therefore, the admitted air must be cooled and in extremely cold weather it must be warmed. There are special mechanical devices for accomplishing both of these purposes.

Shape of storage plants.

Many storage plants are planned without consideration of the factor of the most economic shape; that is, the most efficient as well as the most economical size of plant to be constructed. The first consideration is that the plant should be planned to supply the required floor space and cubical capacity. In figuring the size of storage rooms to accommodate packages of fruits, the size of the fruit packages must be taken into consideration and enough space must be made to allow the air to circulate between the stacks or bales of packages. A barrel of apples, for example, requires 8 to 10 cubic feet. Another factor which must be considered is the economical handling of the packages in the storage rooms. Where the storage season is comparatively short, the extra expense of piling in high stacks must be considered. Where, however, the storage season is to be long, higher stacks may be made and, consequently, rooms of greater height will be most economical. After the size and the cubical contents of the chamber are determined, the next consideration is the shape of the plant or room.

The most economical shape for a storage plant is the cube. This is due to the fact that the ratio between cubical contents and exposed outside surface is smaller for the cube than for any other shape. It is important to take this into consideration because of the fact that there is no perfect insulating material and, consequently, when the ratio of exposed outside surface is very high, the rate of heat leakage into the room is increased considerably when the shape of the room differs materially from the cube. Such a room must have either much heavier insulation or considerably more power must be supplied to offset the greater heat leakage. Sometimes limitations of space, as for example, utilizing parts of buildings, require that the rooms be of odd shapes. When this is necessary, it will require considerably more insulation or power, as suggested. The capacity of the plant must be determined by the nature of the commodity to be stored. Large rooms are easier to maintain at a desired temperature after the entire load of the room is reduced to the required temperature. In large rooms, however, it is more difficult to cool uniformly unless some special attention is given to the placing of the pipes, or the duct openings where forced air circulation is used. For periods of short storage, such, for example, as the more perishable fruits like berries, rooms of smaller capacity are more desirable than very large rooms.

Insulation.

There are three ways in which heat may be transferred: radiation, conduction, and convection. Radiation is the transference of heat from one body to another through a third medium without perceptibly affecting the medium. The heat which one feels when standing before a fire is radiant heat. The conduction of heat is accomplished by the passing of heat from one body to another by contact with the heated body. The heat that one feels when the hand is placed on a warm pipe is conducted heat. Heat is transferred by convection by means of a third medium, usually air. In attempting the construction of storage houses, all three methods of heat transference must be taken into consideration. The heat actually radiated is comparatively small in storage buildings. The quantity of heat transferred by conduction is greater, but the most

important problem of heat transference is through convection currents. In order to offset this heat transference, specially constructed walls must be provided. A storage chamber is a room so constructed that the temperature may be maintained at or near a constant point. In order to offset changes of temperature, sufficient refrigerating capacity must be provided, or some means to prevent the actual transmission of the heat from the outside to the inside of the room. The latter provision is known as the insulation of storage rooms. Therefore, the rooms are constructed in such a way that the walls act as barriers against the transmission of outside heat into the room, or the loss of heat of the storage room to the outside in extremely cold weather. The best insulation against heat transmission is a vacuum. If it were possible to surround storage rooms with vacuum walls, the heat leakage into the room would be very slight, and after the rooms were once cooled to the desired point, it would not require machinery of great capacity to maintain a low temperature. It has been found difficult, however, to maintain a vacuum under ordinary circumstances. The outer air pressure is constant and leakage of air into the vacuum walls, although slight, gradually destroys the insulating effect. Attempts at vacuum construction on a large scale have not been successful.

Air spaces, that is, walls made air-tight so that the air is closely confined, have been thought to be efficient insulation. Still air is a necessity where this method of insulating the wall is used. A slight leakage into the wall is sufficient to allow outer air to enter and, consequently, to destroy the insulating effects. In walls constructed of free air spaces, convection currents occur within the spaces, which act as effective transferers of heat either inward or outward, as the case may be. Fig. 3701 shows the action of convection currents within air spaces. When one air space is used, the transfer of the heat is very easily accomplished, as shown by the direction of the air currents—shown by the arrows in the diagram. Simply thickening the walls, therefore, does not act as a sufficient insulation. The insulating effect of air spaces is considerably improved by breaking up the walls into smaller air spaces. The diagram shows the convection currents occurring in walls of one, two, three, or four air spaces. As the number of spaces is increased, the effect of convection is very greatly reduced, so that a wall consisting of four air-tight spaces may be considered as fairly efficiently insulated. It is, however, extremely expensive to construct these air-tight divisions, and some other means of insulation is desirable.

It is preferable to use some material to fill the walls. Such a filler breaks up the air spaces within the walls and confines the air in the small interstices between the particles. In this way, the air held within the wall approaches more nearly the desirable "dead-air" condition. Convection currents actually occur in filled walls, but they are very sluggish and the effect is very slight. Filled walls are effective barriers against heat conduction or radiation, provided, of course, that poor conductors of heat are used.

The most effective insulating material is a substance of low-heat conductivity which has many pores or cells. These cells are filled with air (practically still air); consequently the efficiency of the heat barrier is increased. A number of substances are effective as insulation for storage walls. The requirements for an

insulating material, besides non-conductivity of heat, are as follows:

1. Odorless; any strong odor would affect the goods stored in the rooms.
2. Moisture-proof or low capacity for moisture; dampness decreases the efficiency as an insulating material, and some substances ferment or rot when damp.
3. Vermin-proof; there should be no inducement for rats or mice to nest in the walls.
4. Non-liability to inherent disintegration or spontaneous combustion.
5. Lightness in weight; not only on account of the reduction of the actual weight of the walls, but because light materials are usually the best non-conductors of heat.
6. Elasticity; when packed firmly in the walls the material should not settle, as any settling within the walls results in open spaces in the insulation. After the walls are once constructed, these inequalities cannot be reached for repairs without completely rebuilding the walls.
7. Relative cheapness and economical handling; the material should not be so high in cost as to be pro-

3701. Diagrams illustrating convection currents in walls consisting of one to four dead-air spaces.

hibitive. In addition, the material must not be of such a nature that its economical handling is impracticable.

8. Must allow of practical application in general work; very specialized material which would not lend itself to general conditions could not be considered as efficient insulating material.

The list of materials available for insulation may be divided into two classes: Those that can be considered as commercial insulation—that is, materials which are manufactured especially for insulating purposes; and common or waste materials.

Among the most common of the first class are the following: granulated cork, cork sheets or boards or bricks, hairfelt, linofelt, mineral wool, and lith.

Granulated cork is considered to be one of the best and most effective insulating materials. It is prepared from the trimmings of cork mills, and when used in the granulated state is simply filled into the walls and packed tightly. Cork sheets, bricks, or boards are manufactured of the cork particles which are compressed in molds at a high temperature. There is no cementing material used, the heat and pressure being sufficient to liquefy the natural gums and resins of the cork and these hold the particles together. Cork boards or sheets are also made by the addition of asphaltum pitch which renders the particles water-proof but may decrease the insulating efficiency.

Hairfelt is manufactured of waste cattle hair which is washed and deodorized. It is pressed or felted together by special machinery into sheets from $\frac{1}{4}$ to 1 inch in thickness.

Linofelt is a patented material manufactured from

flax fibers. It is prepared in sheets or quilts, from $\frac{1}{4}$ to $\frac{1}{2}$ inch thick, somewhat like cotton-batting. These sheets are ordinarily quilted between water-proof paper. This material is used largely for insulating household refrigerators and refrigerator cars.

Mineral wool is also known as rock-wool, rock-cotton, rock-cork, or silicate cotton. This material is usually made from the slag of blast furnaces with the addition of limestone. Rock-wool is usually made from

3702. Diagram showing proper construction of wall insulated with mill shavings.

a mixture of granite particles and limestone. The crushed rock is mixed with coke and fused in furnaces at a temperature of about 3,000° F.; the molten slag or rock is run out through the bottom of the furnace by a high-pressure steam blast. This blows the slag into very fine shreds or fibers, much resembling fleece or wool. The result is a material which contains from 92 to 96 per cent air spaces and, although consisting primarily of a substance of high-heat conductivity, is fairly efficient as insulation. It is practically vermin-proof, fire-proof, and not liable to decay. It absorbs moisture very easily, and one of the greatest disadvantages is the difficulty of handling. The fibers are very penetrating and are glass-like, which result in considerable inconvenience in handling the material.

Lith is a manufactured insulation composed of flax fibers, lime rock-wool, and water-proofing compound. It is prepared in boards of standard sizes and thicknesses and is accepted as a standard insulation by refrigerating engineers. It is a very efficient insulating material.

Common forms of insulating material which are usually at hand or can be easily obtained for the construction of storage buildings are: straw, chaff, hay, dry grass, dry leaves, hulls of various grains, sawdust, and mill shavings.

All except sawdust and mill shavings can be considered as suitable only for temporary structures. These materials are all fairly efficient as non-conductors of heat provided they are dry and means are used to keep them in a dry condition after being built into the

walls. There is also some danger from the depredations of rats, and the greatest possible care must be used to prevent these rodents from gaining entrance. Sawdust from different woods has about the same insulating effect. The sawdust must be thoroughly dried, otherwise its efficiency as insulation is very greatly impaired and, in addition, there is danger of fermentation and heating, and even spontaneous combustion. It is more difficult to obtain dry sawdust than mill shavings, and whenever sawdust is used it should be very carefully dried before being placed in the walls. It has not as great elasticity as mill shavings and, consequently, is likely to settle after packing unless very carefully pressed into place.

Mill shavings consist of small chips and shavings from planing mills. This material has largely replaced sawdust for insulating purposes and is much more effective. It is obtained easily in a dry condition, owing to the fact that the mills of this kind usually work dry lumber. It is much more elastic than sawdust and does not pack or settle down. If thoroughly dry, and means are taken to keep it so, it is a very efficient insulating material and will remain in good condition for many years. It should be packed in the walls at the rate of eight or nine pounds to a cubic foot.

Whenever walls are filled with insulating material in loose condition, much will depend upon the method of constructing the walls. Not only is it necessary to use the lumber and insulating material in a dry condition, but unless the walls are properly built, the insulation will not remain dry any great length of time. Walls that are not practically air-tight allow the outside air to gain entrance and to mix with particles of insulating material; condensation of moisture takes place, and the insulating efficiency of the material is seriously impaired. The conditions for the condensation of moisture upon the insulation particles are ideal unless special means are used to prevent it. Contact with the inside walls lowers the temperature of the insulation to such an extent that when the warmer air from outside comes into contact with it, the moisture is deposited and absorbed. Therefore, it is necessary to build the walls in such a way that they will be practically air-tight.

This is accomplished by having layers of elastic water-proof paper on the outside and inside of the walls. The proper method of constructing such walls is shown in Fig. 3702. The wall consists of two layers of matched boards on each side, between which the water-proof paper is placed. The figure also shows the proper method of overlapping the paper at the corners. It is very essential that these details be attended to; it is also necessary to prevent the tearing or breaking of the paper when placing it, and for this reason only elastic paper should be used. The more brittle forms of paper are so easily broken that it is almost impossible to place them without seriously injuring them. Any breaks at the corners or tears in the paper will allow considerable air leakage into the walls and very seriously impair their efficiency. This is probably one of the most important details in the construction of storage houses, both for cold-storage and for common-storage purposes. Too great stress, therefore, cannot be placed on this point.

Storage temperatures; humidity.

The general principles governing the application of low temperatures to the preservation of fruit products depend primarily on the fact that temperature is the most important factor governing the life activities of these products. A fruit or vegetable is a living organism in which the functions or life processes are continually proceeding as long as the body remains in a normal condition. The various processes of ripening depend upon the chemical and physiological changes within the

organism. Contrary to common belief, the life processes do not cease when the fruit is removed from the parent plant. These processes continue until the life cycle of the organism is completed. The fruit organisms respire and transpire just as plants do and the measurement of the end products of these respiration and transpiration processes serves as an index of the rate at which the life activities are proceeding. Definite measurements on a large scale show that the temperature factor is the most important from the standpoint of the rate at which the life activities proceed. Each fruit organism has a definite life span or life cycle, and it is easy to see that if in any way these activities can be retarded, the life span can be lengthened. The reduction of the temperature of the organism materially reduces the life processes, and the rates at which these activities proceed is slackened to such an extent that the definite life functions of the organism may continue slowly during a long period. The retardation of the life activities through the reduction of the temperature thus induces a slowness of the rate and a consequent increase of the length of the life span. This is the essential physiological principle upon which the cold storage and common storage of fruits depend.

The most satisfactory temperature for storage purposes is one which is low enough to reduce the life activities to a minimum but not sufficiently low to stop them entirely. It is important to remember that a complete stoppage of the life functions of a fruit organism means the death of it, and when this occurs, the fruit soon thereafter becomes unfit for food.

Much careful investigation remains to determine the most satisfactory temperatures for various fruit products. Many factors are involved. One of the most important of these is the condition of the product when it is placed in storage. Fruits of the same kind and even of the same variety may have different storage qualities and require different storage treatments, depending upon the place where the fruit is grown or its previous handling. Until these factors are all known and controlled, it is unsafe to say that any particular temperature is exactly correct for all fruits. For this reason, it is difficult to limit storage periods by law, because no arbitrary limit can be satisfactory for all fruits. It would not be safe, for example, to state that apples should not be kept longer than a certain length of time. The same is true of pears, but with this fruit the conditions are even more extreme. Different varieties of apples and pears may be held in storage different lengths of time, and all warehousemen know by experience that the same varieties of fruits produced in different districts or in different seasons have different storage qualities.

The proper storage temperature for a fruit should be the lowest possible—that is, the lowest temperature at which the fruit can be held without actual injury. This is due to the fact that when other conditions are satisfactory, the lower it is possible to hold a given product the longer it will remain in good condition. This means, then, that the freezing point of the fruit can be safely approached under ordinary conditions. There are, naturally, some important exceptions to this general rule.

As has been indicated above, different fruits have different rates of life activities, and the more perishable fruits are those that have the most rapid rate. For example, perishable fruits like berries, peaches, and some varieties of grapes have very rapid life activities, while the less perishable fruits such as apples, pears, and the citrus fruits have a very low rate of life activities. This condition affects the storage period of a given fruit even under the most satisfactory condition. It is a well-known fact that the more perishable soft

fruits cannot be held in storage for any great length of time. The naturally short life can be lengthened considerably but not to the same extent that the life span of the harder fruits can be lengthened.

Berries of various kinds, cherries and cranberries, may be hard frozen and held in such condition for several months when the product is intended for use in making sauce or pies. When the hard-frozen fruits are removed from storage they must be used immediately, as they soon become soft and break down physiologically.

The most desirable cold-storage temperature for a fruit, according to present knowledge of the subject, is 32° F. for apples, pears, peaches, plums, strawberries, raspberries, loganberries, blackberries (short time), cherries, grapes, mangoes, celery, lettuce (short time). An apparent exception is in the case of apples from the middle coast section of California. The apples produced in this section require a somewhat higher storage temperature, due to the fact that a peculiar discoloration of the flesh develops when this fruit is held at the standard 32° temperature. This fruit is more safely held at about 35°. The varieties which are affected by this trouble are principally Yellow Newtown, Missouri Pippin, and, to a less extent, Yellow Bellflower. This apparent storage weakness seems to be confined to the mid-coastal district; apples from the mountains and other districts of the Pacific coast seem to possess normal storage qualities.

For potatoes, 35° to 40° F., for citrus fruits, 45° to 50° F., are the most satisfactory temperatures. Citrus fruits seem to be an exception to the general rule that fruits of low life activities can be held at temperatures near their freezing-point. Investigations show that temperatures below 45° F. are injurious to citrus fruits, except for a very short period. The low temperature seems to affect the skin of the fruit, inducing the deterioration by scald or stains and the development of various fungous diseases. At a temperature of 45° to 50°, or a common-storage temperature of 50° to 60°, citrus fruits may be held for several months without serious deterioration, provided means are taken to prevent shriveling. Lemons are sometimes held from four to six months at common-storage temperatures without serious deterioration, when humidity conditions are carefully attended to.

The proper humidity of the air of storage rooms is an important factor. Very little investigation of this

3703. Diagram showing proper method of ventilating a storage cellar.

important problem has been undertaken and, consequently, the fundamental factors governing the general principles of humidity conditions in storage rooms have not been definitely determined. Much shriveling of fruits in cold storage has been due largely to excessive evaporation on account of the free transpiration activities of the fruits. Transpiration, or the giving-off of moisture, occurs freely at high temperatures, less freely at low temperatures. The moisture, however, is being constantly given off even at low temperatures

and when the air of the storage rooms becomes excessively dry, the fruit may become seriously wilted by excessive evaporation. The reduction of the temperature of the air reduces its water-holding capacity; consequently, as the air temperature is reduced to the freezing-point or below, all the excess moisture is removed and the air becomes saturated with water vapor for the temperature at which it is held. The total volume of water vapor is thereby greatly reduced. When the temperature of the air rises without the addition of moisture, its capacity for absorbing moisture from the fruit increases and, consequently, the drying effects due to refrigeration may be seriously overdone. The most satisfactory humidity condition in the storage room has never been correctly determined. Experience shows that the humidity condition should be as high as possible to prevent shrinkage from evaporation, but without danger from excessive moisture, which may induce the growth of mold.

Excessive wilting of fruits in storage is not always due to evaporation. Fruits which are picked in an immature condition wilt and shrivel seriously under the most satisfactory storage conditions.

3704. Diagram showing ventilating air space and proper positions of ventilators in a common fruit storage house.

From what has been said, it will be seen that humidity conditions in artificially refrigerated chambers very largely take care of themselves, due to the ameliorating effects of the refrigeration of the air. The control of the conditions becomes more important at high storage temperatures, e. g., it is very important in the storing of citrus fruits without artificial refrigeration. Under these conditions the humidity of the storage rooms or cellars must be held relatively high, because the higher temperature has a decided effect upon the life activities of the fruits, and a correspondingly high humidity is, therefore, essential. The fruit must be very carefully watched; otherwise, mold will occur when humidity conditions are too high. A relative humidity of about 80 to 85 per cent at a temperature of 50° F. has been found to be most satisfactory under the conditions which exist in California lemon-storage houses. It would not be safe to say that this humidity percentage is exactly correct, because the complexity of accurately measuring humidity conditions under different temperature conditions renders the problem very difficult.

Common storage.

The difference between common storage and cold storage has been explained (page 3246). The principal difference is that with cold storage, artificial refrigera-

tion is used while in common storage there is no artificial refrigeration. Common storage is sometimes referred to as "dry storage," inferring that cold storage must necessarily be wet. This assumption is incorrect; cold storage is not in any way connected with moisture nor is it more likely to produce moisture in storage rooms, provided they are carefully conducted, than is common storage. Any excess of moisture in the cold-storage room means some defect in the construction of the plant or in its operation. It has been said that cold-stored fruits are more moist when withdrawn from storage than common-stored fruits. Here again, the difference is due to the difference in the temperature. The cold fruit from the artificially cooled storage chamber, coming in contact with the warm moist air, will condense moisture on its surface. Fruits from the ordinary storage rooms may not be cold enough to condense moisture; hence, the assumption that the cold-stored fruit is more moist than that from common storage.

Common storage is not practicable for all fruits. The very active or highly perishable fruits cannot be held satisfactorily under common-storage conditions because there are no ready means at hand to cool them to the desired temperatures. Citrous fruits are eminently adapted for common storage. The curing of lemons is really a process of common storage. Winter varieties of apples and pears are also suitable for common storage. This method of storage is used to a considerable extent in New York and is coming into wide use in the Pacific Northwest. In the operation of common-storage rooms, dependence is placed on the ventilation for the cooling. There is a vast difference between ventilation due to the actual change of air by the opening of windows or flues into the room and the circulation of air. Ventilation means the admission of outer air, and circulation may refer merely to the movement of the air within the room or plant, the same air being used over and over again. This distinction is necessary because frequently the circulation of the air within the room is designated as ventilation.

In the operation of common-storage rooms, the rooms are ventilated, or outside air is admitted, when its temperature is low enough to cool the fruit. The ventilators are closed during the day and during warm periods, thus conserving to a certain extent the low temperature obtained through the low-temperature outside air. It is essential, therefore, that there be cold nights or cold weather; otherwise, common-storage plants become mere cool-storage chambers, and the storage season is considerably shortened, due to the fact that the relatively high temperatures result in a high rate of life activities in the stored products. When the temperature of the common-storage room can be maintained somewhere near 32° early in the season there is no apparent reason why the storage period should not be extended to almost the same length of time that can be obtained under cold-storage conditions.

In the early part of the season, especially when there are few cold nights, it is difficult to reduce the temperature of the fruit to the desired point. This is the critical period, as the rapidity with which the temperature of the fruit can be reduced determines the length of time the fruit may be held in good condition. It is easy to see, therefore, that under common-storage conditions, usually the fruit must remain at a comparatively high temperature for a considerable length of time. The ripening which occurs during this period of high temperature cannot be offset by low temperatures later on. The developments which take place in this period of high temperature shorten the life span under storage conditions, and when the temperature is high and the fruit held warm for a considerable length of time, the storage period may be very materially shortened. There are frequent warm spells during the fruit harvest, and the nights are not so cold.

There is a widespread notion that common-stored fruits are better than cold-stored. It is difficult to understand how this opinion has become so fixed in the minds of many persons. It is probable that one reason is the fact that a comparison of fruit from common storage and from cold storage is really a comparison of fruits held under different conditions. The common-stored fruit is usually withdrawn after a shorter period and, therefore, may be in good condition. The cold-stored fruits are usually held for a long period and frequently the period is too long for the best condition of the product. Many carefully planned experiments show conclusively that cold-stored fruit remains in better condition during a longer period and, when carefully handled, remains in better condition after withdrawal than common-stored fruit. If the fruit is promptly and rapidly cooled at the beginning of the storage period, its life activities will be retarded to such an extent that the life span will be very materially increased. If this can be done under common storage, there is no reason why the fruit cannot be held in good condition. Frequently the fruit is placed in common storage during the fall and early winter; frequently also the common-storage room where the fruit is held is only a makeshift. After being held in this unsatisfactory condition for a time, the fruit is placed in cold storage later in the season when market conditions have not been favorable. This is the wrong way to store fruit. The time when cold storage is most urgently needed is at the beginning of the storage period, in order that the fruit may be promptly cooled. It would be more reasonable to remove the fruit from cold to common storage later in the season, because common-storage rooms may then be held in a satisfactory condition and the fruit would be in a much better condition for holding.

It has been suggested that a combination of cold and common storage is really the solution of many of the problems of successfully holding the fruit in the district where it is produced. Where ice can be obtained at a reasonable price, it can be used at the early part of the storage season to cool the fruit promptly and quickly. After weather conditions are such that cool nights prevail, the place can be operated as an ordinary common-storage plant for the remainder of the season.

Common-storage buildings.

The earliest form of common-storage buildings for fruits was caves or pits. These were used for the storage of fruits under the impression that the earth is cool and also to protect the fruit from freezing in extreme winter weather. The earth is cooler than the outside air in summer; in winter it is warmer, under ordinary conditions. Ordinarily, the temperatures of the ground range from 50° to 60° and this temperature remains fairly uniform below the frost line which, of course, varies materially under different climatic conditions. The protection against freezing in winter, therefore, is ideal, but unless some artificial method of cooling the room is at hand, the temperature of the earth itself is too high for best storage conditions. In the later development of the cave storage, ice was used to cool the chambers; this was naturally not satisfactory, due to the dampness and to the difficulty of ventilating.

Cellars have been a favorite place for common storage. They are open to the same objection as caves. Unless specially constructed and special means be provided for ventilation, the cellar is not an efficient fruit-storage chamber, except for short periods of time and for the protection of the products against freezing in winter. Cellars are difficult to ventilate unless special appliances are used. They may be ventilated by means of flues but the efficiency of such conduits is dependent upon differences in temperature, otherwise there will not be any appreciable movement of the air. Wind flues may be used; these are flues which have a funnel-

like arrangement at the top, so designed that the mouth of the funnel is kept to the wind by means of a vane. The pressure of the wind entering the funnel creates a circulation of air through the cellar. In some instances these wind flues are found to work the reverse way during periods when the wind does not blow. In ventilating a cellar, there must be an outlet opening corresponding to the inlet opening. This is to allow the escape of the warm or foul air from the room. If it is possible to provide openings on all sides of the cellar, a current of air can be easily circulated through the room, especially if there is a breeze. The intake flues should open near the floor of the cellar. Fig. 3703 shows the proper placing of the inlets and outlets designed to ventilate cellar rooms. There should be a large number of openings to facilitate the ventilation of the cellar as rapidly as possible. Cellars are useful only for relatively high-temperature storage, and the necessity for insulating the walls of them is not sufficiently appreciated. The insulation must be sufficient to protect the cellar against the comparatively high temperature of the earth; otherwise, the temperature

3705. Diagram showing common-storage house with false floor and false ceiling, and exhaust fan for forced ventilation.

of the storage room cannot be held materially below the earth temperature.

Common-storage rooms are frequently very cheaply constructed. The idea is prevalent that any old shed can be made to serve the purposes of a common-storage room for fruits or other products. The insulation is poor and, as a consequence, there is great fluctuation in the temperature. Proper insulation in the construction of a common-storage room is really more important than that for cold storage because there is no means of regulating the temperature except by ventilation or change of air, while the cold-storage room has artificial or mechanical means, the capacity of which can be increased to offset the heat leakage. To be effective, all common-storage plants must "conserve cold," and the necessity to provide efficiently against heat leakage through the walls, therefore, becomes doubly urgent.

The insulation for a common-storage room or building may be of the commercial kinds, which have been described, or use can be made of some of the cheaper common materials, such as straw, chaff, dry leaves, sawdust, and mill shavings. The principles of constructing the walls and using the insulation are all applicable to common-storage buildings and should be followed carefully if one expects to secure the best results. In addition to the insulation of the walls, an outer ventilat-

ing space is effective, especially during warm weather. Fig. 3704 is a diagram which shows the proper method of constructing a common-storage wall with an outer ventilating space designed to carry off most of the heat absorbed by the outer wall. Windows are not satisfactory for ventilating common-storage plants. The openings should be at or near the floor and there should be corresponding openings at the top, as shown in the diagram illustrated by Fig. 3704. The taking-in of the outer air depends upon the difference in temperature between the bottom and top parts of the building; therefore the greater the number of openings, the more rapidly the air of the room can be changed. A false floor is a distinct advantage, and will add very materially to the efficiency of the plant. The construction and use of such a false floor is illustrated in Fig. 3705. When the false floor is used, the openings or ventilators should open directly under the floor, so that the outer air may

3706. Diagram showing construction and proper arrangement of ventilators in combined ice and common fruit storage room. Dotted arrows show directions of air when ice cooling is used.

have an opportunity to pass directly beneath the product stored in the room. A forced circulation is very much more satisfactory and will result in a more rapid change of air. In order to accomplish this, an exhaust fan should be placed at the top of the chamber, so that the air of the room can be drawn to the fan and exhausted into the outer air, thus creating a reduction of the air pressure within the rooms and the consequent drawing-in of the air to the room when the ventilators or traps of the room are open. Fig. 3705 shows a cross-section of such a chamber and the proper location of the fan.

In the combination of the ice cooling and common storage, ice and salt or even ice alone can be used to cool the fruit at the early part of the season. The tube method may also be used with ice and salt or the gravity-brine system before described can be advantageously utilized.

A diagrammatic cross-section of a combined ice-cooled and common-storage plant is shown in Fig. 3706. The design permits of the closing of ventilators

and the opening of trap-doors, to utilize direct cooling from the ice stored above. A similar arrangement for the use of ice in small rooms can be made with the ice room or bunker placed at the end or side of the chamber.

The Figs. 3707 to 3713 are diagrams showing the proper construction of walls and the method of insulating walls, ceilings, and floors both with commercial insulation and common materials. Figs. 3707, 3708, and 3709 show the proper method of applying insulation to stone, brick, and concrete walls; while Figs. 3710, 3711, 3712, and 3713 show the method of applying insulation to ceilings and floors.

In the operation of common-storage plants, the fruit must be carefully watched at all times. The temperature should be taken frequently. It is very desirable that the actual temperature of the fruit itself be recorded from time to time. For this purpose, glass thermometers, the bulbs of which can be imbedded in the fruit, are desirable. Long-stem thermometers can be obtained which have the bulb at the end of a long tube and the recording scale at the upper end, thus allowing the temperature to be taken at the interior of the package. It is possible to note temperature conditions of the fruit by observing the influences of the temperature within the package upon the temperature of the room. When the fruit is thoroughly cooled throughout the mass, there will be little change in temperature after the closing of the ventilators. If the insulation of the room is effective, the change in the temperature of the air of the room will be very slight. If, however, there is any considerable heat left in the body of the fruit, there will be a marked and rather abrupt rise in the temperature after closing the ventilators.

Careful attention to the condition of the fruit is necessary also to determine whether the humidity of the room is too high or too low. This will be shown by the appearance of the fruit. Excessive ventilation, i. e., the circulation of large volumes of air through the room, will cause shrinkage or shriveling, while insufficient circulation will favor mold. Special recording hygrographs which record the changes in humidity almost instantly upon a chart are very convenient adjuncts to storage rooms in order to observe the humidity conditions. Instruments which record both relative humidity and temperature on the same chart are obtainable. When one desires to operate properly, an investment in such an instrument is a distinct advantage.

The length of time which different fruits may be held varies for the kind of fruits and even for different varieties of the same kinds of fruits. The importance of storage, then, is relative; it is most important for fruits

3707. Diagram of stone, brick, or concrete wall with two layers of commercial insulation. 1, 8-inch wall; 2, asphalt or cement; 3, 2-inch commercial insulation; 4, asphalt; 5, 2-inch commercial insulation; 6, cement finish or T and G boards.

which may be held longest. A short period of storage may be relatively as important for the short-season fruits, such as the perishable berries. The ability to hold these fruits even for a few days may result in a great profit due to changes in market conditions. The holding of short-period fruits for a brief time is important for canneries because the fruit may be held in its best condition and this may result in a great saving to the canneries or factories when sufficient help cannot be obtained.

Storage is most important for the apple. This fruit has the longest storage period of all. There are cases in which apples have been held in fair condition for as long as two years. It is, of course, not profitable or desirable to hold apples as long as this. The most important season is during the winter and spring months and until the fresh fruits come into the markets. As indicated above, the cold storage of the apple has resulted in making it an all-the-year-round fruit. Many varieties are held from one season until the summer apples of the next season are available. The so-called winter varieties are held to the best advantage.

There are three classes of apples: summer, fall, and winter. The summer varieties have the shortest storage season. The fall apples have a longer season but not so long as the winter varieties. It is upon the last class that dependence is placed for late-season supplies. The following fall varieties are the ones chiefly used for storage and, as a general rule, these may be held in first-class condition until the Christmas holidays or until the middle of January: McIntosh, Fameuse, Yellow Bellflower, Jonathan, Grimes. The following winter varieties are the ones of most importance for storage purposes: Baldwin, Ben Davis, Winesap, Yellow Newtown, Gano, Rome Beauty, Esopus, Northern Spy, Stayman Winesap, Banana, Ortley, Delicious, Lawver, Rhode Island Greening, Northwestern Greening, and York Imperial.

The varieties of pears which may ordinarily be used for storage are: Bosc, Easter, Anjou, Clairgeau, Comice, Howell, Winter Nelis, Duchess, Sheldon, and Kieffer.

Factors underlying successful storage.

By means of investigations of the United States Department of Agriculture, the factors which govern the successful storage of fresh fruits have been carefully determined. The investigations have been extended through a number of years, since the work of Powell with apples in 1901-1902. There has been more work with apples than with other fruits but studies of the storage of grapes, peaches, pears, plums, cherries, and

small-fruits have also been made. It is beyond the scope of this article to give in detail the results of researches with all of these fruits. In general, it has been found that there is a very definite relationship between the character of the fruit and the treatment given it in preparing it for storage, and its behavior in storage. The results from extensive experimental storage holdings have been consistent throughout; there have been no exceptions to the general principle of this definite relationship. It has been found, for example, that the influence of the place of production is frequently of great importance. The place and condition under which the fruit may be grown have a

material influence on its behavior in storage. This is contrary to prevailing impressions but it is definitely certain. The character of the soil upon which the fruit is grown may have an important bearing on its storage quality. For example, apples from the lighter loam soils have better keeping quality than fruit grown on heavy or wet soils. In the study of the storage of grapes, it was found that the fruit grown in certain types of soils have better market and storage qualities. Some Tokay grapes, grown in California in light sandy soil, reach the limit of their market condition in November, while grapes of the same variety grown in heavy black soil may be kept in good condition until after Christmas. The Emperor grape, which has become an important storage fruit in California, is produced under best conditions in the red soils of the higher benches of the foothills of the Sierras. The same variety grown under valley conditions where the soil is of a different character, does not color so well and does not have as good storage qualities. The same is true of the Almeria grape, which is likely to become a very important storage fruit in California. At present the supplies of this grape come almost exclusively from Spain. The grapes are packed in granulated cork and the Spanish product is frequently held for several months in common stor-

age. California-grown Emperor and Almeria grapes are packed in redwood sawdust and are successfully held in cold storage, the former until the middle of January, and the latter several months later.

Differences of one to three months in the storage qualities of the same varieties of apples have been found to be due to the place of production. Mention has already been made of the storage weakness of the Yellow Newtown and other varieties grown in the Central Pacific coast district of California. The same varieties grown in the Pacific Northwest and in Virginia and other sections of the country are free from this particular weakness.

The care of the orchard and method of culture given the trees have been found to be important factors. The character of tillage, pruning, age of trees or vines are also considerations, especially when taken in connection with different climatic conditions. The fruit from young trees or vines has weak storage qualities; it is usually large, coarse, sappy, and cannot be held in storage nearly so long as fruit of the same variety from older and more mature trees. Dense-headed trees produce fruit of poor color; the green, poorly colored apples produced under such conditions do not have high storage quality. Such fruit is very susceptible to the trouble known as storage-scald; the loss from this source may be avoided and the storage quality of the fruit may be much improved by better orchard methods. Pruning to open up the crowns of the trees will improve light conditions, especially where intense sunlight does not naturally prevail. Some growers actually cut away the leaves of the vines to allow light to color and mature the grapes to better advantage. In sections such as the arid regions of the Pacific coast, where intense light conditions prevail, the opening-up of the tree crowns must be done with greater care. It is not necessary to open up the trees to such an extent as is necessary where intense light is not naturally available.

Late growth also affects the storage qualities, as it prevents the proper maturing of the fruit. In irrigated districts, the late application of water may stimulate the growth while the fruit is maturing and this may result in sappy poorly colored fruit of low storage quality. The question is often asked whether the fruit produced in irrigated districts has as good storage qualities as that from non-irrigated districts. The impression seems to prevail that it does not. This is erroneous, as has been shown by extensive investigations. It is manifestly impossible to compare directly fruit grown under irrigation in one district with fruit grown without it in another. The varieties are different and other factors may operate to change conditions in the one case or the other. There are thousands of boxes of irrigated fruits held in the best possible condition in storage, and this would seem to be a direct answer to the question of the keeping qualities of fruits grown under irrigation. It is necessary, of course, to have the irrigation properly applied; if overdone by applying large quantities of water late in the year in order to induce large sappy growth, the results are fruits of poor storage qualities.

In sections which have dry summers, where tillage is depended on to conserve the moisture, the work must be thoroughly and properly done; otherwise, the moisture supply in the soil will be deficient, and the trees or vines will be under stress on account of the lack of sufficient moisture. Fruit produced under such conditions has very low storage quality. Any condition of soil, climate, and orchard treatment which results in the production of abnormal fruits may be important governing factors in their behavior in storage. Spraying for the control of insects and diseases is important from the storage standpoint. It is necessary that this work be thoroughly and properly done, as insect and disease injuries render the fruit liable to

deterioration. The insect or disease may be of itself the cause of the decay or deterioration. There is also an indirect effect: when the trees are weakened by the effect of insects and diseases, the results may be weak fruit of poor storage quality.

Seasons affect the quality as well as the quantity of the crop. In seasons of unusual drought, for example, the fruit may be so weakened that its storage qualities may be seriously impaired. On the other hand, unusually wet seasons result in the production of sappy fruits which deteriorate rapidly. In seasons of unusual drought, the orchards under irrigation have a distinct advantage, provided the application of the water is properly adjusted. The effect of frost may be beneficial or otherwise: A crop may be thinned to such an extent that its condition may be somewhat improved since over-production by the tree may result in weak fruit, while the thinning will improve this condition. On the other hand, where the frost is sufficient to destroy most of the crop, the remaining fruits may be sappy and overgrown and otherwise weak. The frost-injured fruits themselves have not as high storage qualities. During an unfavorable season, fruit which has been placed in storage must be carefully watched throughout the entire storage period. Its condition should determine the length of time it is held. The effect of storage is such that attempts to hold the fruit beyond its normal life period result in serious losses. Fruit of low vitality, when the limit of its life is reached, will deteriorate very rapidly after withdrawal from cold storage. It is important, therefore, not to wait until the fruit is ready to break down before withdrawal.

Fully matured well-colored fruit keeps best and longest. Early notions that fruit for storage should be picked in an immature condition are erroneous. The fruits which are picked before full maturity have low storage qualities. There is serious deterioration from shriveling and, in case of apples, there is a definite relationship between the occurrence of scald and the state of maturity at which the fruit is picked. This disease is a peculiar browning or scalding of the skin of the fruit. It does not extend into the flesh except under very severe conditions. Immature fruit is seriously affected while fully mature fruit of the same variety may be held without deterioration from this cause.

Full maturity means that the "ground color" is plainly developed, the flesh of the fruit firm, and the seeds fully grown and colored. This principle is correct for all fruits with the possible exception of most varieties of pears and lemons. Over-ripeness must be avoided. A designation of the proper stage of maturity for picking fruits is difficult; it must be learned by actual experience. Over-ripeness or over-maturity occurs when the fruit begins to soften. In some instances, growers are in the habit of allowing the crop to remain on the trees until all the fruits are fully colored. This is a wrong practice, as some fruits mature before others, and if allowed to remain until all are colored, may become over-ripe or over-mature. It is best to make more than one picking, especially with the earlier ripening varieties. Fruits on the outer branches exposed to full light ripen first and the best results in storage are obtained when these are held separately, unless the trees are well and properly pruned.

Reference has been made to the importance of cooling the fruits promptly and rapidly, in connection with the ripening processes and life activities and the effects of temperature on these factors. Delay in storage, which means delay in cooling, during warm weather may shorten the storage period from one-third to one-half. Experiments with apples held at a comparatively high temperature for a period of ten days or two weeks before cooling, showed that fruit thus treated could be held only from one-third to one-half as long as the same varieties promptly stored and cooled after pick-

ing. There is also a direct influence on the occurrence of scald. Prompt cooling, as a rule, prevents the occurrence of this disease. This factor is of special importance for early-season fruits or early varieties of apples like Jonathan. The practice which prevails in many sections of allowing the fruit to accumulate for some time before placing it in storage is likely to result disastrously if the season happens to be warm. This is especially true where the fruit must be packed while warm. The ideal condition is the placing of the fruit under refrigeration immediately after picking from the tree and the nearer this can be approached in practice, the longer the fruit can be held in storage.

The proper storage temperature for different kinds and varieties of fruits has already been referred to. The influence of a low temperature, especially for apples, is most important. Experiments show the occurrence of scald to be less severe at 32° than at a higher temperature. The use of a low temperature is also important because of the rapidity with which the fruit within the package can be cooled. In operating either a common- or cold-storage plant, the temperature of the fruit is an important factor to consider. When a fruit is first placed in the storage room, a considerable length of time may be required to reduce its temperature to the desired point, if means are not at hand to increase the cooling effects. In cold-storage rooms the cooling can be hastened by holding the air of the rooms at a temperature several degrees lower than the desired temperature. A temperature of 25° to 27° F. may be safely maintained until the fruits in the packages approach the storage temperature. In this way the operator can materially hasten the cooling effect, and this hastening is desirable. It is commonly assumed that the cooling should be gradual, but as yet there is no experimental evidence to indicate that rapid cooling is at all injurious.

The investigations of the United States Department of Agriculture show conclusively that the character of the treatment given the fruit in preparing it for market or storage has a material influence upon its keeping quality. Fruits which are roughly handled and bruised or injured to any extent have their storage qualities seriously affected, and decay and deterioration follow the injuries. There are some forms of decay or deterioration which cannot develop unless there are injuries of some kind on the fruit. A break in the skin will allow blue mold to gain entrance, while a sound skin may prevent the development of this form of decay. Blue mold is one of the most common forms of loss both in common and cold storage and occurrence of this trouble is due almost exclusively to rough handling. The blue mold does not grow upon the sound skin of a healthy fruit. The importance, then, of handling the fruits with extreme care throughout all the processes of picking, grading, and packing cannot be too strongly emphasized. Bruises or breaks in the skin may mean a decayed fruit. This general principle has been established through a long series of careful investigations and thus far there has been no exception.

There are other decays which affect apples and other fruits: the principal diseases affecting apples are brown- or ripe-rot, anthracnose, and bitter-rot. These diseases are not dependent upon the care in handling the fruit so far as the occurrence of bruises or injuries is concerned. The spores are present on the fruit when it is packed and the control of the disease in storage goes back to the orchard treatment and the control of the fungi on the trees. All three of these decays occur on the trees as canker spots and the spores which inhabit the fruits develop from these cankers. Control of the cankers by cutting out or spraying will materially reduce the occurrence of decay in storage.

There are other forms of deterioration which, so far, have not been traced to any definite organism. These

are obscure physiological diseases and result in the breaking down of the flesh of the fruit, or in burning of the tissues, or in a scalded appearance of the skin. These physiological troubles have been found to be due, at least to some extent, to rough handling or to pressing. A physiological breakdown also occurs in fruit which is over-ripe when it is stored. It also occurs seriously in fruit which has been delayed in cooling after picking. Physiological breakdown also occurs in fruit which is held beyond its normal life limit.

Ordinary storage-scald has already been referred to. The nature of this disease is unknown but it is supposed to be due to the action of enzymes upon the skin of the fruit. There is another form of scald which, for want of a better term, has been designated as "soft scald." Ordinary storage-scald does not soften the skin except in the most advanced stages. The soft scald produces a softening of the skin and also of the flesh directly beneath the skin. It occurs also in more or less distinct areas or zones, sometimes extending completely around the fruit. The nature of this disease is obscure and, so far, storage treatment, orchard treatment, and temperature effects do not seem to have any bearing on it. It has been attributed to the freezing of the fruit in storage and, while definite results from the effects of freezing have not been obtained, it is possible that in storage rooms of uneven temperature conditions portions of the rooms may have temperature conditions sufficiently low actually to injure the fruit.

For discussion of precooling, see the article *Transportation*.

A. V. STUBENRAUCH.

STOVE PLANTS. The term "stove" applied to plants undoubtedly originated from the method of heating the structures in which plants were grown before the advent of hot water and steam. Glasshouses such as then existed were heated by stoves and flues, usually made of bricks. Such structures came to be called stovehouses or stoves, and the plants grown in them "stove-plants." (A "greenhouse" was in those days an unheated glasshouse in which plants were merely kept alive over winter.) These terms still exist in England, but are applied to strictly tropical plants or those requiring a warm temperature for their successful culture in glasshouses. In this country such plants are usually spoken of as warmhouse or tropical plants.

In England, at the present time, more distinction is made in the names applied to plant-houses than in this country. For example, "greenhouse" in England means the coolest glasshouse only, while in this country the name is usually indiscriminately applied to all glasshouses. The names applied to plant-houses in England are therefore: stove, for tropical plants; intermediate house, for plants hailing from warm-temperate climates; greenhouse, for those plants requiring the least degree of heat. A conservatory or show-house is one in which plants are placed while in flower and usually kept at a cool temperature.

In practice such terms may be greatly modified to suit local conditions; for example, glasshouses are sometimes named cool-temperate house, warm-temperate house, tropical house, palm-house, acacia- and succulent-house, experiment-house and propagating-house, the temperatures and moisture conditions being regulated to suit the requirements of each class of plants.

The cultivation of stove plants is too heterogeneous a subject to be treated exhaustively in a single book, because the stove contains thousands of dissimilar plant treasures from the tropics, especially those found at low altitudes. In general, the stove is the house which requires the most expense and care, the greatest heat and the highest atmospheric moisture. For the general principles of its management, consult *Greenhouse Management*, p. 1408.

EDWARD J. CANNING.

STRANVÆSIA (for Wm. Fox-Strangways, English botanist). *Rosaceæ*, tribe *Pomeæ*. Ornamental woody plants grown for the handsome foliage and the attractive flowers and fruits.

Evergreen trees or shrubs: lvs. entire or serrate, with subulate stipules: fls. white, in terminal many-fl. corymbs; calyx turbinate, 5-toothed; petals 5, generally obovate, clawed, stamens about 20; styles 5, connate to the middle or higher; ovary 5-celled, the cells 2-ovuled: fr. a small pome, crowned by the persistent incurved calyx-teeth, the cells usually 1-seeded.—Two or 3 species in China and Himalayas. These are handsome evergreen small trees or shrubs with generally oblong rather large or medium-sized lustrous lvs. and small white fls. with quickly deciduous petals in often ample corymbs, followed by attractive red subglobose pea-sized frs. They are suited for warmer temperate regions, but *S. Davidiana* var. *undulata* seems to be hardier and with protection survives the winter as far north as Mass. Prop. is by seeds or by cuttings of half-ripened wood under glass.

Davidiana, Decne. (*S. Henryi*, Diels). Shrub, 4-20 ft.: young branchlets silky-villous: lvs. on slender hairy petioles $\frac{1}{2}$ – $\frac{3}{4}$ in. long, oblong to oblong-lanceolate or oblanceolate, acuminate, cuneate at the base, entire, green and glabrous on both sides except pubescent on the midrib above and often beneath, $2\frac{1}{2}$ – $4\frac{1}{2}$ in. long: fls. white, $\frac{1}{2}$ in. across, in loose, more or less villous corymbs 3–4 in. across; stamens about as long as petals, with red anthers: fr. subglobose, scarlet, $\frac{1}{4}$ – $\frac{1}{3}$ in. across. June. W. and Cent. China. Var. *undulata*, Rehd. & Wilson (*S. undulata*, Decne.). Lvs. elliptic-oblong to oblong-lanceolate, usually wavy on the margin, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long: corymbs $1\frac{1}{2}$ –3 in. across, sometimes nearly glabrous. B.M. 8418.

Nússia, Decne. (*S. glaucescens*, Lindl. *S. glauca*, Baill.). Small tree: young branchlets like the infl. villous at first, soon glabrous: lvs. obovate to oblanceolate, short-acuminate, serrulate, 2–5 in. long: fls. white, $\frac{1}{2}$ in. across, in corymbs 2–5 in. broad; stamens about half as long as petals, with yellow anthers: fr. subglobose, orange, $\frac{1}{2}$ in. thick. June. Himalayas. B.R. 1956.

ALFRED REHDER.

STRATIOTES (Greek, *soldier*, referring to the sword-shaped leaves). *Hydrocharitaceæ*. **WATER SOLDIER**, or **WATER ALOE**. Perennial hardy aquatic herb of small ornamental value but considerable botanical interest: st. very short, stoloniferous: lvs. clustered, all sessile, submerged, linear-lanceolate, fleshy, acute, margin with many pointed teeth: scapes short or elongated: spathe extending above the water, unisexual, 2-lvd.: fls. white; male fls. 2 to several in a spathe, pedicelled, perianth 2-rowed, 3-merous; stamens 11–15; pistils rudimentary or none; female fls. solitary in the spathe, short-pedicelled, perianth similar to male; staminodes many, linear; ovary oblong, somewhat 6-celled: fr. on a recurved pedicel, laterally exerted from the spathe, ovoid, acuminate.—One species, Eu. The plant has a distinct calyx which is not the rule among monocotyledons.

One of the peculiarities of stratiotes is that in summer the whole plant rises to a point near the surface when it is only partly submerged, and later in the season it drops below the surface. Young plants do not act thus. It is propagated by side shoots from the base of the leaves. Toward fall and early winter these shoots are merely bulblets and are readily detached from the plant and are in a good condition for traveling. It is not desirable for the aquarium on account of its spiny leaves. (Wm. Tricker.)

aloides, Linn., is the only species in the genus. It is sometimes called **CRAB'S CLAW** or **FRESHWATER SOLDIER**. In England the planting of this species is discouraged from the fact that it spreads too rapidly. Peduncles rising from among the lvs. to a few inches

above the water, much thickened at the top, bearing a spathe of 2 bracts: ovary and stigmas nearly as in *Hydrocharis*, but the fr. is ovoid and somewhat succulent. G. 2:466.

F. TRACY HUBBARD.†

STRAWBERRY. The species of *Fragaria*, grown for the fruit. (For the morphology of the strawberry fruit, see Vol. I, page 40.)

The strawberry is an herbaceous perennial. It naturally propagates itself by means of runners that form chiefly after the blooming season. Seedage is practised only with the Alpines, and in raising new varieties. Division of the crown is useful for propagating varieties that are practically runnerless, as the Bush Alpine and Pan-American. The runner plants, either transplanted or allowed to remain where they form, will bear the following year. Usually the plants will continue to bear for five or six years, but the first and second crops are generally the best. Good results are sometimes secured from plants over ten years old, especially when they are grown under hill training and intensive culture, but this is a special practice. It is therefore the custom to plow up strawberry beds after

they have borne from one to three crops. The better the land and the more intensive the cultivation, the shorter the rotation. In market-gardening areas and in some of the very best strawberry regions, the plants are allowed to fruit but once. The plants therefore occupy the land only one year and the crop works into schemes of short-rotation cropping. When the bed is fruited more than one year it should be renewed immediately after the crop is harvested. In the case of matted or spaced rows, this consists of reducing the number of old plants, using the plow, disc-harrow, cultivator, or hoe, and in stirring the soil to provide favorable conditions for the rooting of new runners. It is customary, also, to mow the leaves and burn them. In the case of hill or hedge-row plants, renewal consists of mowing and in drawing about an inch of fresh soil around the plants, so that new roots will form above the old ones. Throughout the North, and as far south as Kentucky and Missouri, beds are fruited but one year, occasionally two, rarely longer. In Florida and the coastal plain of the Gulf states, the plants occupy the ground but six to eight months. In the lower Mississippi Valley and on the Pacific coast, beds are fruited three to six years. The strawberry delights in a rich rather moist soil and a cool season. It can be grown in the cool part of the year in the South and thereby becomes one of the most cosmopolitan of fruits. The young plants may be separated from the parent and put into new plantations in August; but under average conditions in the North it is usually better to wait until early the following spring, since the weather is likely to be too hot and dry in the late summer or fall. South of Virginia, Tennessee, and Arkansas, and on the Pacific coast, most of the planting is done in the fall or winter months. Plants that have not borne are best for setting. They are plants of the season: that is, plants

3714. Strawberry plant ready for setting.

CVIII. Strawberry.—The Climax variety

which start in the spring of 1916 are fit for planting in the late summer or fall of 1916 or in the spring of 1917. These plants have many long, fresh, light-colored roots. Fig. 3714 shows such a plant, with the roots trimmed for planting. Fig. 3715 shows a plant that has borne. This plant bore fruit, say, in 1915, and has thrown up a new crown in 1916. The old dead crown is seen at the right. The young growth is lateral to this old crown. The roots are relatively few and are hard and black. These plants sometimes make good plantations under extra good care, but generally they should be avoided.

Two- or 3-inch pots are sometimes plunged under the new runners in June and July, and they become filled with roots in two or three weeks. These pot-grown plants are excellent for fall setting in the home-garden,

but they are seldom employed in extensive commercial practice on account of their expense. Almost as good results can be secured by setting strong layer plants. (Fig. 3716.)

In Florida and in the coastal plain of Georgia, Alabama, Louisiana, Mississippi, and Texas, beds need to be reset annually, in September or October; plants set at this time produce a good crop in the following February, March, and April. The plants may be produced at home, but more commonly are secured from the North.

In hill training, each plant is allowed a space by itself, cultivation is given both ways, and no runners

are allowed to set. Hill or stool training is practised commercially in Florida, the Gulf States, and on the Pacific coast, and, to a slight extent, in northern market-gardens. It is the most practicable method under irrigation, and in a very humid climate. The chief disadvantage is the heavy expense of removing all the runners. Hills give choicer berries than narrow matted rows, but the yield is not so heavy. For commercial results, plants are generally trained in narrow rows. The old method was to plant in rows 3 to 3½ feet apart and the plants from 12 to 15 inches apart in rows, keeping off the runners until late in July and then allowing the runners to grow and root at will, making a wide matted row. In this system some plants are almost on top of others, the roots barely in the ground, and they suffer in a season of drought. The rows are so wide that to pick fruit in the center it is almost necessary to crush fruits on the outside of the row. This system gives few large first-class fruits, and is now passing away. The largest and highest colored fruits are found on plants along the outside of the rows; therefore have as many outside rows as possible. This may be accomplished by having rows closer together and much narrower. The rows are made from 30 to 36 inches apart and the plants from 18 to 24 or even 30 inches apart in the rows, much depending on the prolificacy of the variety as a plant-maker. If the plants used for a new bed are strong and start into growth vigorously, the first runners are used, as it has been found that under most conditions the plants about twelve months old yield the greatest number of fine fruits. These first runners are usually "bedded-in,"

i. e., planted by hand, training them along the wide way of the rows, using from four to eight of the first runners and cutting off those growing later. This method of planting allows cultivation both ways until the runners start, retaining moisture and saving labor in hoeing.

In the "narrow matted row," which is now used more than any other method of training, the runners are allowed to set at random until they have made a row 12 to 24 inches wide; subsequent runners that encroach upon the tilled middles are cut off. In the "spaced row," the early runners are set by hand at more or less regular distances apart until a row 12 to 24 inches wide has been formed; thereafter all other runners are cut off. In the "hedge row," two to four runners are set from each mother plant, and are kept in alignment, forming a single, double, or triple hedge row; all other runners are removed. The drift is steadily away from the matted row toward the spaced row and hedge row. Surplus runners are pulled off or are cut off with a knife, hoe, or one of the many types of runner-cutters that may be attached to the cultivator. Circular cutters are used for hill plants. In late fall, the matted row may be thinned by pulling out the weaker plants with an iron rake or spike-toothed harrow.

In the North, strawberries are usually mulched in the fall, in order to protect them from alternate freezing and thawing in the winter and early spring and to prevent the soil from heaving. In some cases the mulch is allowed to remain on the plants rather late in the spring, in order to retard the season of bloom. Sometimes the crop may be retarded a week or ten days by this means. It should not be removed until settled spring weather has come, nor left on so long that the plants bleach. The mulch is more necessary in regions of light and precarious snowfall than in those in which

3716. Pot-grown strawberry plant.

3715. Old strawberry plant, usually not desirable for setting.

3717. Heavy mulching of strawberry plants, as practised in parts of the North.

the snow blanket is deep and lies all winter. In regions of deep and continuous snowfall, a heavy mulch is likely to prove injurious. Experience has shown that the best mulch is some strawy material. Along the seacoast, salt hay from the tide marshes is much used. In interior places clean straw, in which there is no grain to sprout and to make weeds, is very largely employed. (Fig. 3717.) In the South, pine needles are used. Some-

times loose strawy manure is used, and the mulch adds fertilizer to the soil as well as affords protection. Corn fodder, leaves, brakes, seaweed, evergreen boughs, and other wild herbage are used occasionally. Cowpeas and sorghum are grown for mulching material when straw is scarce. The practice of growing oats, barley, or some

3718. Sexes of strawberry flowers: at the left a perfect flower; at the right a pistillate flower; in the middle, stamens few.

other small grain between the rows of strawberries, to fall down and mulch the berries, is not generally advisable. Under ordinary conditions the mulch is 3 or 4 inches deep over the plants after it is fairly well packed down. It is not always possible, however, to mulch as heavily as this, since the material is likely to be expensive when one has a large area. The mulch is usually applied late in the fall after the ground has frozen, and, if the material is abundant, both the plants and the intervening spaces are covered. In the spring the mulch is raked from the plants as soon as they begin to start. Some persons allow it to lie between the rows as a cover to retain moisture and to keep the berries clean. The most expert growers, however, prefer to take the mulch from the field and to till the plantation once or twice before the plants are in bloom; the material is then returned and spread on the loose soil between the rows and beneath the vines. In the northern prairie states, heavy mulching is essential. For western Minnesota and Dakota a covering of at least 6 inches of straw is advised. This mulch is easily provided, since straw is so abundant in that country that it is often burned as the readiest means of getting rid of it. When not mulched in that region, the plants are likely to be killed outright or to start with a very weak growth. Mulching for winter protection is not necessary south of Virginia and Missouri, but mulching to keep the fruit clean is as profitable in the South as in the North. The fruiting mulch is applied after the plants begin to bloom. Pine "straw" is used most. A large handful is dropped upon each plant; the leaves soon push through. Rarely is it desirable to cover the entire area between the rows. On the Pacific coast, strawberries are not mulched, as it is not necessary for winter protection, and it would interfere with irrigation.

Strawberry flowers may be either perfect or imperfect, and the nature of the flower is characteristic of the variety. In some kinds, the flower is perfect or hermaphrodite (having both stamens and pistils) and is consequently self-fertile. These are commonly called staminate varieties. In others it is pistillate, producing little or no pollen, and requiring a pollen-bearing variety to pollinate it. (Fig. 3718.) There are no modern varieties bearing

3719. Strawberry nubbins.

only staminate or sterile flowers, although such forms were common about 1840. The perfect-flowered varieties differ greatly in the amount of pollen they produce. Some, as the Crescent and Glen Mary, bear so few stamens that they are practically pistillate or sterile. Any variety will fertilize any other variety if it bears sufficient pollen and if the two kinds bloom at the same time. The variety used as a pollinizer does not affect the shape, color, and quality of the fruit of the pistillate sort, as was once thought. It is preferable to plant an early-blooming pollinizer on one side of the rows of the pistillate sort, and a late-blooming pollinizer on the other side. When planting pistillate varieties, every third row should be a pollen-bearing kind. Pistillate varieties as a class are somewhat more productive and hardy than staminate varieties as a class; but this fact has little weight, since some staminate sorts are fully as prolific and hardy as the best pistillate varieties. It is an inconvenience to be obliged to mix varieties for pollination; hence pistillate varieties are steadily declining in popularity. In time, all North American varieties will be staminate, as is now the case in England. The horticultural bearing of

the sexual characters of the strawberry flower was first clearly explained in this country by Nicholas Longworth, of Cincinnati (see page 1585; also his essay on the subject in his "Cultivation of the Grape," 1846, and the "Strawberry Report" of the Cincinnati Horticultural Society, 1848). When many of the achenes or "seeds" of the strawberry are not fertilized or are killed by frost or other means, the berry fails to develop at that point and a "nubbin," or imperfect berry, is the result (Fig. 3719). Nubbins are usually most abundant late in the fruiting-season, when the pollen-supply is small and when the plants are relatively exhausted.

Ordinarily the common varieties bear but once a year, in the spring. Under certain conditions of temperature and moisture they may become "double croppers," and give a fall crop, also. In the South, particularly in southern California, the bearing season may be extended over several months; but no varieties were consistently everbearing in the North until 1898, when Samuel Cooper, of Delevan, New York, found the Pan-American in a row of Bismarck. European everbearers, which are hybrids of the common strawberry and the Alpine, do not succeed here. The numerous descendants of the Pan-American are true everbearers; they yield a small quantity of berries throughout the season from spring-set plants. It is better, however, to cut off all blossoms until midsummer; then there will be considerable fruit from August until frost, but not so much as a good crop from a spring-bearing variety. The culture of the everbearers does not differ materially from that of other sorts, save in the cutting of the blossoms weekly, which is a heavy expense. They require rich soil and an equable supply of moisture; they fail in a dry season. The market for berries in late summer and fall is limited, and the cost of picking is heavy. The following spring, a year from the time they were set, the everbearers produce a good crop, perhaps equaling that of single-bearing sorts. This is one point in which the North American everbearers are distinctly superior to those of Europe. The everbearers have little commercial future merely for supplying summer and fall berries, but their habit of bearing a heavy spring crop, also, may make them useful to some growers who cater to personal or near markets. They are not likely to find favor with those who grow strawberries for the wholesale market. The everbearers are valuable mainly for the home-garden.

The cost of growing an acre of strawberries under commercial conditions in Oswego County, New York, is approximately as follows:

Rent of land, two years.....	\$11 00
Plowing and fitting.....	6 00
Plants.....	15 00
Setting plants.....	4 00
Cultivation.....	16 00
Straw for winter and fruiting mulch.....	15 00
Labor—hoeing, pulling weeds, etc.....	10 00
Total cost.....	\$77 00

Many northern growers raise berries at a much less cost, and a few exceed this sum, especially when located near a large town where rents are high; but it would be safe for one about to engage in strawberry-growing to figure close to this total, aside from the cost of fertilizer.

A Michigan grower estimates that the cost of producing and marketing an average yield of 200 sixteen-quart crates to the acre is \$1.56 a crate; and the average net return 88 cents a bushel, giving a profit of \$88 an acre. This is fairly representative of field culture in the North. The high cost of production in Florida is in marked contrast. As reported by a Plant City grower it is:

Interest on investment and land.....	\$20 00
Interest on equipment.....	10 00
Preparation of land.....	10 00
Fertilizer.....	40 00
Plants.....	40 00
Setting plants.....	5 00
Cultivation.....	10 00
Picking 3,000 quarts at 2½ cents.....	75 00
Grading and packing at 1 cent.....	30 00
100 crates at 15 cents.....	15 00
3,000 boxes.....	11 00
Hauling to station.....	10 00
	\$276 00

Still another phase of strawberry economics may be observed in southern California. There it costs 3½ cents to produce and market a pint box of strawberries, and the average selling-price is about 5 cents. Although yields of 10,000 to 15,000 quarts to the acre are common, the expense of picking is very heavy, since the season lasts six to eight months, and it costs \$150 an acre to set a new field, since it requires 30,000 plants to the acre. These examples serve to illustrate the very wide range of conditions. The average yield, according to recent census statistics of the United States and Canada, is 1,700 quarts to the acre. The average selling-price, net to the grower, is 6 to 7 cents a quart. Authentic yields of 25,000 to 27,000 quarts to the acre have been secured under intensive culture.

New varieties of strawberries are raised from seed with the greatest ease. The generations of strawberries are short and new varieties soon find favor. The varieties change so frequently in popular

3720. Wilson strawberry. (×½)

estimation that it is impracticable to recommend a list of them in a work like this. The first great American berry was the Hovey, introduced in 1838. (Fig. 1861, Vol. III.) The most popular single variety has been the Wilson (Fig. 3720), introduced in 1854 and still popular in Canada and the northern Pacific states. It held almost undisputed control of the market from 1860 to 1880, when the Crescent and Sharpless secured recognition. These three are the most important North

American varieties; two-thirds of the 348 varieties of known parentage have descended from them. Other old favorites, now no longer grown, are the Cumberland, Triumph, Downer Prolific, and Charles Downing. European varieties do not succeed here; notable exceptions are Jucunda, and Triomphe. Over 1,800

varieties of North American origin have been introduced but less than 150 of these have attained prominence. The oldest North American variety now cultivated is the Longworth, introduced in 1851; it is still prized in the San Francisco market. The dominant commercial varieties of today are the Dunlap, Haverland, Marshall, Klondyke, Aroma, Gandy, Glen Mary, Bubach, Brandywine, Clark, Warfield. At least

3721. Gandy strawberry. (×½)

fifty others are grown to a considerable extent. The accompanying pictures (Figs. 3720–3725) show types of American strawberries.

The strawberry has been in cultivation but a short time, as compared with other fruits. It has been grown in gardens less than 600 years, and was not cultivated commercially to any extent until early in the nineteenth century. The first record of garden culture is in France, early in the fourteenth century. This was the wood strawberry, *Fragaria vesca*. The common wild strawberry of eastern North America, *F. virginiana*, was introduced into Europe early in the seventeenth century. Neither species showed much promise under cultivation. *F. chiloensis*, which is native to the Pacific coast of America, was brought to Europe from Chile in 1712, by M. Frezier, a Frenchman. See *Fragaria*. Although the berries are large, this species found little favor because of shy bearing and poor quality; it gave practically no improved varieties. Near the middle of the eighteenth century the Pine strawberry (referring to the pineapple fragrance of the fruit) appeared in Europe, and became the principal progenitor of the garden strawberry. The botanical origin of the Pine is obscure. One view is that it was a form of *F. chiloensis*; another, that it resulted from the hybridization of that species with *F. virginiana* in European gardens; all the early importations of the Chile were pistillate plants, and varieties of the Scarlet were commonly planted with them. The first of the modern race of large-fruited varieties was the Keens' Seedling, originated by Michael Keens, of England, in 1819; it was a Pine, and from it have sprung most of the European varieties of today. The Hovey, from which modern North American varieties have descended in large measure, was undoubtedly a Pine in part, but there is considerable evidence that one of its parents was a variety of *F. virginiana*.

Wild strawberries were so abundant in North America that there was no garden culture of this fruit until about 1770. The Alpine and Hautbois types of strawberries (*F. vesca* and *F. moschata*) were introduced then from Europe, but did not become popular; preference was given to transplanted wildlings of the Scarlet. These species have never been grown here except by a few amateurs. Commercial strawberry-culture began soon after 1800, mainly in the vicinity of the four largest towns of that period—Boston, New York, Philadelphia, and Baltimore. The varieties used were slightly improved forms of *F. virginiana*, notably Large Early

Scarlet, Hudson's Bay, Early Hudson, and Crimson Cone. These persisted until the introduction of the Wilson. The first variety of any fruit produced in North America by hand-crossing was the Hovey, originated by C. M. Hovey, of Boston, in 1836. The Hovey was a failure as a market variety, except in a few places, but it was an excellent amateur variety and greatly increased interest in strawberry-culture. The heated discussion of "Longworth's Theory" (1841-1845) concerning sex in the strawberry also stimulated interest and offered a practical solution of a pressing cultural problem. As yet, however, the strawberry was mainly a fruit of the open fields and home-gardens; the commercial planting was very limited. The total quantity of fruit marketed in 1854 was less than 40,000 bushels, the product of about 1,400 acres.

3722. Haverland strawberry.
($\times \frac{3}{8}$)

The variety that marked the beginning of commercial strawberry-culture in North America was the Wilson, originated by James Wilson, of Albany, New York, in 1851. Until then, strawberry-culture had been difficult, and the results very uncertain; the Wilson thrived under even indifferent care. Its introduction was followed by a remarkable increase, coincident with the extension of railroads, in commercial planting. The "strawberry fever" that swept over the country between 1858 and 1870 has not been equaled in intensity by the boom days of any other fruit. The inevitable reaction came between 1870 and 1885. This was emphasized by the heavy losses from shipping berries long distances without refrigeration. The experiments of Parker Earle, of Cobden, Illinois, resulted in the first successful use of the modern refrigerator-car system, in 1887, and made possible the great shipping districts of today, many of which are over 1,000 miles from their markets. There are now approximately 150,000 acres of strawberries in the United States, and 14,000 acres in Canada. The value of the crop is \$20,000,000 annually. The

strawberry is fourth in commercial importance among deciduous fruits, being preceded by the apple, peach, and grape. The most important shipping districts, according to the Census of 1909, are Maryland, 14,292 acres; Tennessee, 10,761; Missouri, 9,048; New Jersey, 8,684; Michigan, 8,051; Arkansas, 7,361; Ontario, 7,702; Delaware, 7,194; Virginia, 6,606. Sussex County, Delaware, has the largest county acreage, with 6,404 acres in 1909.

There are several serious fungous diseases and insect pests of the strawberry. White grub is controlled by avoiding newly plowed sod land when setting the bed; weevil, by planting largely of pistillate varieties or profuse-blooming staminate sorts; leaf-roller, by spraying with arsenate of lead, and burning the leaves; root-lice, by setting clean plants in clean land. The several types of leaf-blight (Fig. 3726) may be prevented to a considerable extent by spraying with bordeaux, but it is more practicable to plant resistant varieties. The fundamental treatment of all these is to fruit the bed but once, or at most but twice, and to grow succeeding crops on other land, cleaning up the old plantation thoroughly after the last fruiting. Short, quick, and sharp rotations and clean culture do much to keep all enemies in check.

The American book writings on the strawberry are: R. G. Pardee, "A Complete Manual of the Cultivation of the Strawberry," New York, 1854, and subsequent editions; A. S. Fuller, "The Illustrated Strawberry Culturist," New York, 1862, and subsequent editions; J. M. Merrick, Jr., "The Strawberry and its Culture," Boston, 1870; Charles Barnard, "The Strawberry Garden," Boston, 1871; T. B. Terry and A. I. Root, "How to Grow Strawberries," Medina, Ohio, 1890; L. J. Farmer, "Farmer on the Strawberry," Pulaski, N. Y., 1891; A. F. Wilkinson, "Modern Strawberry-Growing," 1913. Aside from these writings, the strawberry is well treated in various books devoted to small-fruits and to fruit in general, and in the horticultural periodicals. S. W. FLETCHER.†

Strawberry-growing in the South.

The strawberry is by far the most important small-fruit grown in the South, being raised commercially in every state. The industry is more concentrated in the South than in the North. This concentration is probably due to the fact that nearly all of the strawberries are shipped by freight to distant markets. The strawberry industry in the South has developed as an independent unit, or as an adjunct to truck-growing rather than in connection with other fruit-growing enterprises.

An important consideration in growing strawberries for northern markets is the selection of a location where the soil and climatic conditions are conducive to early ripening of the fruit, so that there will be little competition from regions farther north. In many southern sections where strawberries are grown on a commercial scale, shipments practically cease as soon as berries from a more northern location begin to move in car lots. This is due to the fact that toward the end of the picking-season the berries are small and cannot compete successfully with the larger fruit from a region nearer the market that is just beginning to harvest its crop.

While strawberries are grown on nearly all types of

soil in the South, sandy and gravelly loams are considered best. A warm quick soil, although poor, is preferable to a heavy retentive soil well supplied with plant-food. Plant-food can be supplied by the addition of fertilizers, but the physical condition of the soil can be modified only with difficulty and loss of time by cultivation, drainage, and the addition of humus. The soil for strawberries should be well supplied with humus in a well-decomposed state. Many growers think that new land is essential for good results, but when old soils are well supplied with organic matter they will yield as large crops as new soils.

Few soils in the South that are adapted to strawberry-growing are rich enough to produce large crops of fruit without the addition of fertilizers. Stable or barnyard manure is the best fertilizer for strawberries as it supplies both humus and plant-food. It is best, however, to apply the manure to the crop preceding the strawberries in order that it may become well-decomposed, and so that most of the weed seeds will have germinated.

When manure is not available, commercial fertilizers are applied in large quantities, but these should be used in connection with green-manure crops such as cowpeas, soybeans, velvet beans, vetch, and clovers. Some growers use as high as one ton, or even as much as a ton and a half, of commercial fertilizer to the acre. However, under most conditions, 1,000 to 1,500 pounds of a fertilizer analyzing 2 to 3 per cent of nitrogen, 6 to 8 per cent of phosphorus, and 6 to 8 per cent of potash, should be sufficient. On land where legumes have been grown, a part of the nitrogen may be left out. It should be borne in mind that large applications of commercial fertilizers are profitable only when used on soils in good physical condition, and well supplied with humus.

There are three systems of growing strawberries in the South: the hill system, the hedge-row system, and the matted-row system.

In the hill system the plants are set separately, one plant in a place, and no new plants are allowed to form. The plants are set 12 to 14 inches apart in rows 3 to 3½ feet apart. This makes a large, vigorous plant, producing large uniform berries which ripen evenly. This system is followed in Florida. The quantity of berries produced is not so large as under the other systems, but the quality is better and the percentage of first-class berries larger.

In the hedge-row system the plants are set 10 to 18 inches apart in rows 3 to 3½ feet apart, and runners are allowed to form plants along the row in a strip a few inches wide. This system is practised in the southern part of the lower tier of southern states, with the exception of Florida, where the hill system is used.

In the matted-row system the plants are set 15 to 18 inches apart in rows 3½ to 4 feet apart. The runners are allowed to form plants 6 to 9 inches on either side of the row. Sometimes the plants are allowed completely to cover the ground. This system probably produces the largest crop of berries, but the fruit is usually smaller and does not ripen so well as under the other systems.

Strawberries are planted in Florida any time from June to November, whenever the soil and climatic conditions are favorable. In other southern sections of the South Atlantic and Gulf Coast states, the plants are set in late summer or autumn. In all other sections of the South, the plants are usually planted in late winter

or early spring, and no crop is allowed to be produced the first season.

The length of time that a field should be allowed to produce fruit depends upon many conditions and varies in different parts of the South. In sections where weeds and grass grow very rapidly and where the picking-season is long, as is the case in the lower South, usually only one crop is grown. In the upper sections of the South, two or more crops are produced. Some growers allow their fields to produce five or six crops, but under most conditions two crops should be the maximum, as the fields become weedy and the soil compact. It is possible to clean up an old patch in such a way that large crops can be secured for several years, but very few growers give the fields the attention necessary to produce heavy crops of first-class fruit.

When the field bears more than one crop, the strawberries should be thoroughly cleaned out, thinned, cultivated, and fertilized after the fruit has been harvested. As a rule, the best crop is produced on new plantings and for this reason frequent renewal is recommended.

Cultivation should begin soon after the plants are set, and should be continued when-

ever weeds start or a crust forms. Frequent shallow cultivation will make it unnecessary to do much hand-hoeing or hand-weeding. A cultivator which merely breaks the surface without disturbing the roots is to be preferred. Any weeds which interfere with the development of plants or fruits during the picking-season are pulled by hand, or cut off with sharp hoes.

In most sections of the South, some form of mulch is used to hold moisture during the picking-season when the soil is not stirred, to keep the berries clean, and to prevent "heaving out" in regions

where freezes occur. The materials used for mulch are pine straw, oat, wheat, or rye straw, leaves, and marsh hay. These materials are of value as humus when turned under. In sections where freezes do not occur, the mulch is usually applied in late winter.

For best results in growing strawberries a good system of rotation should be followed. In any system of rotation, a leguminous crop should be turned under once in three or four years, and a cultivated crop grown on the area the season before the strawberry plants are set. The following system of rotation is a good one for the South:

1. Strawberries one or two years, followed by cowpeas after the strawberry plants are plowed under.
2. Early vegetables followed by cowpeas or late vegetables.
3. Corn with cowpeas between the rows. The corn stubble and the cowpeas should be turned under for

3723. Bomba strawberry. (Nearly natural size)

strawberries the following year, in case the plants are set in the spring.

In sections where vegetables are not grown commercially, oats may follow the cowpeas turned under the second season.

The varieties of strawberries grown in the South are Klondyke, Missionary, Lady Thompson, Excelsior, Aroma, Gandy, Chesapeake, and Early Ozark. In the lower sections of the South, the Klondyke and Missionary are grown more than all others. For a succession of crops the Excelsior or Early Ozark may be grown for early fruit, the Missionary, Klondyke, and Lady Thompson for medium, and the Aroma or Gandy for late ripening. In the upper sections of the South, the Early Ozark, Chesapeake, Klondyke, Aroma, and Gandy are all grown, but very rarely does any grower raise more than two varieties for commercial purposes.

3724. Belmont strawberry. (Natural size.)

As a large part of the strawberries grown in the South are shipped to distant markets, they must be picked before they are fully ripe. For long distances the berries should be fully grown and about three-fourths ripe. When picked before they are at all colored the berries will shrink and wither, making them unfit for sale.

The berries should be well graded and packed before being shipped. When experienced pickers are employed the best results can be secured by grading the berries in the field, as they are picked, so as to avoid rehandling and the consequent bruising and deterioration of the fruit. The common practice, however, is for expert packers to do the grading and packing in a packing-shed to which the fruit is delivered by the pickers. The top layer of berries should be placed so as to hold them in place, but care should be taken not to put small inferior berries in the center and large berries on top. All types of berry boxes are in use in the South, but the tendency is toward a standard full-size quart box. In some sections of the South, particularly in Louisiana, pint boxes are used for the early shipments. The fruits carry better and the price received is higher; later in the season as fruits become more abundant and the

price is lower, fruit from these same regions is shipped in quart boxes in crates holding twenty-four or thirty-two quarts. A long narrow box is objectionable.

Berries which are well graded and sorted and put in clean, neat, attractive packages of standard sizes command the highest price and sell most readily. The type of crate depends upon the boxes used. Any crate that is substantially built and well ventilated is satisfactory, but the cost is an important consideration, as they are not returned to the shipper. The largest crate that can be handled conveniently is the one to use, as the large ones are cheaper in proportion to the quantity of berries they carry. The twenty-four- and thirty-two-quart crates are in most common use, although in some sections the sixty-quart crate is employed. Crates with hinged lids have the advantage that they can be opened easily and quickly, and as a result invite inspection. A large part of the Florida crop is packed in quart boxes which are placed in pony refrigerators for shipment to northern markets.

The cost of growing strawberries in the South is from \$75 to \$150 an acre, divided about as follows:

Interest on investment (land and equipment).....	\$8 00 to \$15 00
Preparation of land.....	5 00 10 00
Manure or fertilizer.....	10 00 25 00
Plants.....	10 00 20 00
Setting plants.....	8 00 12 00
Cultivating and hoeing.....	20 00 35 00
Mulching.....	15 00 25 00
Total for growing.....	\$76 00 to \$142 00
Picking, grading, and packing 2,000 quarts.....	\$40 00 to \$70 00
Crates and boxes.....	20 00 25 00
Hauling to station, loading, etc.....	5 00 10 00
Total for picking, packing, grading, etc.....	\$65 00 to \$105 00
Total for growing.....	76 00 142 00
Grand total.....	\$141 00 to \$247 00

The lower estimate is about the average for most sections of the South, while the higher figures cover the extreme cost. The average cost in Florida is between the two estimates, but nearer the higher.

H. C. THOMPSON.

The strawberry in California and northward.

California conditions include both those most favorable and most trying for the growth of strawberries. There are situations where, through local topography and proximity to the ocean, winter temperatures are very seldom too low for the growth and fruiting of the plants and where, by summer irrigation to maintain this continuous activity of the plants, it is possible to gather fruit every month in the year. This fact is not, made of much commercial account, however, nor is it widely true that one can have strawberries all the year round in the open air. It is true, however, that even on the lowlands, where the commercial crops are chiefly grown, the winter is so mild that strawberries begin to ripen in shipping quantities as early as March and by proper cultivation and irrigation the fruiting is continued until late in the autumn, and the grower has therefore a very short closed season. The trying condition for the strawberry is found in the long dry summer, which enforces dormancy as early as June on light loams in the more arid localities of the interior. Such soils become dry and hot to a depth of several inches in spite of surface cultivation and cause the dwindling and death of a shallow-rooting plant like the strawberry unless frequent irrigation is begun in time. This trouble is less acute on more retentive soils in regions of lower summer temperature and greater rainfall, and plants in such situations may survive the summer dormancy, but it is true that everywhere in California and even in the more humid states on the north that strawberry-grow-

ing without irrigation results either in failure or only partial satisfaction and the venture is seldom to be commended. It is usually so easy, however, to secure the small amount of water necessary for home production, and the plant when fairly treated is so highly produc-

3725. Shuster (Gem) strawberry. ($\times \frac{1}{2}$)

tive, that a general exhortation to strawberry-growing on an irrigation basis is fully warranted.

There are several species of strawberries indigenous to California, and they are of both littoral and alpine types. Albert F. Etter, of Ettersburg, Humboldt County, California, has worked continuously with these species for more than twenty-five years, by selecting seedlings, and by crossing the species among themselves and with the leading cultivated varieties. He has established an Ettersburg group of new varieties, which for vigorous growth of plant, resistance of drought and true everbearing habit are very notable. Some of them have strictly evergreen foliage under California conditions. For abundant fruiting and for firmness of fruit, some of these varieties have shipping and canning characters new to the strawberry. Etter describes his work in detail in the *Pacific Rural Press* of San Francisco for March 4, 18, and April 1, 1916.

The varieties chiefly grown in California are different from those popular at the East. New varieties from the eastern states and from Europe are freely tried, but few are successful and they retain local popularity after abandonment in their birthplaces. A striking instance of this fact is the continued popularity of Longworth Prolific, Sharpless, Monarch of the West, Wilson, Albany, and the like. Longworth has survived more than fifty years' continued growing. Other popular varieties are Melinda, Jessie, Dollar, Brandywine, Marshall, and Lady Thompson. Brandywine (Fig. 3730) is the most widely approved variety in the state and is standard in southern California, Excelsior and Klondyke standing next in popularity as early varieties, and Americus and Iowa as autumn-fruited varieties. In the central regions of the state, the Dollar and Marshall lead among the newer kinds and the Banner is exclusively grown by some producers for the San Francisco market. Jessie and Dollar are largely grown for

3726. Leaf-blight of strawberry. ($\times \frac{1}{4}$)

shipment to interior states and to the northern coast before the local fruit ripens.

The growth of strawberries is almost wholly in matted rows, the rows usually occupying low ridges only sufficiently elevated to allow the slightly depressed intervals to serve as irrigation ditches and as walks during picking. The slight elevation of the plants also assists in surface drainage, when heavy rains fall during the early part of the fruiting-season, and this promotes early growth and fruiting of the plants. Where the soil is too coarse to permit free rise of water from the depressed ditches, the conditions are reversed and low levees are made to inclose blocks of plants which are irrigated by flooding the inclosures. In the chief commercial regions a fine loam is used and irrigation from the small ditches on both sides of the ridges, which are about 2 feet wide, is the ruling method. Nearly level land is selected and grading is done before planting to reduce dry knolls and fill low places so that the water will flow slowly and will evenly moisten the whole field. Subirrigation by tile has been often advocated but never has been employed to any extent.

One of the chief strawberry-shipping districts in central California is characterized by a shallow loam underlain by an impervious indurated clay or hardpan, which prevents the percolation of the irrigation water and enables growers to maintain a large acreage by means of the small water-supply secured by windmills. In this case water is applied very frequently, even oftener than once a week in some cases, but the total amount for the season is small. Quite in contrast to this is the growth on light deep loams where water sinks so rapidly that the plants suffer, although water is almost constantly running in the ditches. In such cases mulching and sprinkling are the price of success, and these are too costly except on a small scale for

3727. Fancy packing of strawberries, each quart wrapped in paper; a picking-stand on the left.

home supply. The largest producing districts have soils midway between the extremes above noted, viz., deep retentive loams, situated rather low in the valleys and with irrigation available either by ditch system or by wells both flowing and pumped. The pump wells require usually only a short lift, and abundant water is secured cheaply by the use of modern pumps and motors.

In addition to supplying the home markets, which are very good, California strawberry-growers find a good outlet for the fruit all through the region west of the Missouri River. Southern California supplies the southern portion of this district, while the growers in central California, chiefly near Florin in Sacramento County, make large shipments eastward as far as Colorado and northward to all the great interior states and to Oregon,

Washington, and British Columbia before the locally grown fruit in those regions is available.

The states of Oregon and Washington in their areas lying west of the Cascade Mountains have conditions excellently suited to the growth of the strawberry. Their conditions more nearly resemble those in the eastern states than any other part of the coast. The cooler weather and more abundant moisture give a better spring season than that of California, but the season is on the whole much shorter because of the longer winter. Irrigation is also necessary in most places for continued fruiting during the summer. The most famous district is Hood River, Oregon, where arid conditions east of the Cascade Mountains are modified by western influences which reach through the gap in these mountains where the Columbia River flows through. Irrigation is regularly employed and a large commercial product grown. The varieties chiefly grown in this region and in adjacent parts of Washington and Idaho are of local origin, the Hood River (Clark Seedling) and Magoon being widely approved. Jessie, Sharpless, Wilson, Haverland, Crescent, Cumberland, Jucunda, and Parker Earle are also commended by growers in the northwestern states.

E. J. WICKSON.

Cultivation of the strawberry on home grounds.

Of all the fruits which can be grown in the garden, the strawberry offers to the amateur the greatest inducements on account of ease of growing, delicious quality, long season and comparatively quick-bearing habit, and wide geographical range. No garden should be without this important fruit. It can be grown in almost any soil and in so many different ways that even in a most crowded garden some space may be found for it.

The strawberry thrives best in a sunny location but will also do well in partial shade like that from small-fruit bushes or young fruit-trees. Heavy shade draws the vines up, and while a luxuriant growth of foliage ensues there will be but little fruit. On the other hand southern slopes where the berries are exposed to the unbroken rays of the sun will result in scalded fruit unless some artificial protection can be given.

The location of the strawberry-bed in the garden is very important and should be governed to a large extent by the other crops. Remembering that the straw-

watering may be practised, it is often done at the expense of quality in the fruit. Soils may be easily improved. A light soil can be well filled with manure or humus of some sort, and a heavy soil drained with tile. If possible the land should have a slight slope to turn off surplus water in the winter, but if this is impossible,

3729. Strawberry-field grown in matted-row system.

be sure that the bed is not placed in a depression where water collects during the winter.

The preparation of the soil is very important, for a finely rooted plant like the strawberry needs soil well pulverized and free from clods of earth. The land should be planted at least one year with some crop which will require good cultivation. Avoid planting on sod land or land where witch-grass and perennial weeds are abundant. Spading to a depth of at least 1 foot and mixing through the soil a good liberal amount of well-rotted manure will be good preparation for the strawberry-bed. There is, however, on soil naturally rich in nitrogen, danger in putting on too much manure, as an excess will often produce foliage but not fruit. Other fertilizers should be added during the season as the plants grow. Mixed fertilizer should contain about 5 per cent of nitrogen, 10 per cent of phosphoric acid, and from 5 to 6 per cent of potash. All of the artificial fertilizers should not be applied at one time. It is best to make at least three applications during the season as the plants grow and the amount will be governed by the growth of the plants. Artificial fertilizers should not be spread on the foliage. Generally speaking, one pound of the mixture given above in three applications should be ample for six plants during the growing season.

Having prepared the ground as outlined, the next question to settle is the system under which to grow the bed. There are three systems which may be used for the garden strawberry-bed: the wide matted-row, the hedge-row, and the single-hill systems; and as the plan of a system depends very much on the variety grown it will be necessary to consider variety in this connection. In the selection of varieties for the home-garden, the following conditions should be carefully considered: quality, attractiveness of the fruit, productiveness, vigor of plants, season. Many very productive varieties lack quality and attractiveness while as a rule the quality berries are not good commercial varieties and it is often difficult to procure the plants of the better varieties in the nursery.

As it is practically impossible to obtain all of the points outlined above in one variety, it is generally best to plant at least three, not alone to insure a longer season but variety in the fruit is very essential; also some years one variety alone does not do well while with a number of varieties some are sure to succeed. This will be found especially true when late spring frost may entirely ruin one variety and not injure another.

Vigorous-growing varieties with good clean-growing

3728. A prolific row of strawberries, the fruit resting on a mulch.

berry will occupy the land for at least two seasons, such tall-growing crops as corn, pole beans, or asparagus should not be planted too near. Soils often govern location to a great degree. While the strawberry will thrive in almost any soil it is better to choose one which has good water-holding capacity, for although the strawberry will make splendid plant growth in light soil the fruit will not be so good or large if there is a lack of water at the fruiting-season. While artificial

foliage should be chosen. Such varieties are generally to be relied upon. In choosing varieties one should secure those which do well in one's vicinity, for in some cases quality in a variety depends to a large degree on environment.

It is always best to plant at least three varieties so that a long season will be assured. While it is impossible not to have varieties overlap, an abundance at one time during the season is no detriment, for at this time preserving may be done and there are so many ways in which strawberries can be used that an abundance should be sought.

The strawberry is bisexual in its bloom and therefore it will be necessary either to choose varieties which have perfect flowers or have those of both sexes in order to insure perfect pollination. Sex in strawberries does not seem to have any direct bearing on quality or productiveness, although there is a common fallacy that pistillate varieties are most productive and staminate varieties of the better quality.

In the matted-row system of planting, the plants are set 4 by 2 feet apart, and allowed to run so that a row from 2 to 3 feet wide is formed. This is probably the easiest way in which to grow the strawberry. There is great danger, however, that too many plants will be allowed to grow in this system and, in consequence, through overcrowding, the fruit will be small and rather poor. In this system plants should not be allowed to set closer than 6 inches apart and all runners which are made beyond those necessary to cover the ground when at this distance should be removed.

In the hedge- or narrow matted-row system, set plants 3 by 2 feet apart, and allow each to make four or six new plants, which are set so that there are practically three separate rows with the plants in the row about 8 to 10 inches apart. All other plants and runners are removed.

In the hill system, the plants are set in various ways, first in straight rows, 3 feet apart, and the plants in the row from 12 to 20 inches apart, or plants are set in beds 14 by 14 inches or 18 by 18 inches or even 20 by 20 inches apart, and from three to four rows are set, depending on the variety. In this system all of the runners are removed from the parent plant and the bed is generally allowed to remain for about three years.

To obtain strawberries earlier they may be raised in frames as other perennials are grown. The plants are set in August or September about a foot apart in rich garden loam and given good cultivation. The frames should not be more than 8 inches deep. Hill culture is practised in this system and plants are protected during the winter by a light mulch. Glass frames are put on early in March, careful cultivation given, plenty of air and careful watering. This method will advance the crop two to three weeks ahead of the outdoor crop. Such varieties as are suitable for greenhouse culture should be used for growing in frames.

Growing strawberries in a barrel, or rather on a barrel, is practised by those who have very limited space, and while there are many drawbacks to doing this successfully it can be accomplished with care. A clean cider barrel should be used and several 1-inch holes bored in the center of the bottom and a ring of 1½-inch holes about 8 inches apart around the barrel with a space of 8 inches between the rows of holes. If the holes are started near the bottom, it will be possible to get three rows of holes and about eight holes around the barrel. Good strong

pot-grown plants should be secured and a good compost of garden loam. Place in the barrel and over the holes cut in the center of the bottom a piece of 6-inch drain-tile about a foot long, filling the center of the tile with coarse gravel or small stones. Put the roots of the plants into the 1½-inch holes in the sides of the barrel and fill the barrel with the compost, adding pieces of tile to that in the center as the barrel is filled so that the drain-pipe comes up to the top of the barrel. A row of plants may be planted on the top of the barrel so that sides and top are covered. Watering should be done through the drain-pipe and if the coarse material used inside the drain is satisfactory, the plants will take up about the proper amount of water before it all passes through the barrel. The barrel should be carefully protected in winter by covering with straw and pine branches and the top protected so that excessive rain will not get in; elevating the barrel on stones will help the drainage.

Having decided upon the method or system of growing strawberries, the season for planting should be the next consideration. As a rule the early spring, from April 1 to May 10, is the best time to plant in the North, although in many gardens which have to economize space, August and September planting is made necessary,

3730. Brandywine strawberry.

as the strawberry has to follow some of the other early crops, as peas, beans, lettuce, and the like. For August or September setting, pot-grown plants are better than the runner plants unless one can take runner plants directly from one's own bed and transplant them under favorable weather conditions.

To obtain the best pot-grown plants, the runners of the current season's growth should be used, as these make better plants than those of last season's growth which have been placed in cold storage and potted after their natural season of planting has gone by. If layer plants are used in spring, great care should be taken in planting so that the plants may be assured of a good start. Remove practically all of the foliage and cut back the roots at least one-half. If the ground has been prepared carefully the hand may be used in making the hole for the roots, but in stony ground it is best to use a trowel. Be sure that the crown of the plant is not set either too deep or too far above ground. The crown should be on a level with the surface of the soil. When setting, spread the roots out fan-shape and be sure to press the soil firmly about them. Be sure that the rows are straight. Various devices are used on commercial

farms but for garden culture nothing is better than a line for securing straight rows.

Whether set in spring or fall, cultivation of the soil should begin as soon as the plants are set and kept up until late September, when cultivation should cease and the plants given a chance to harden up for the winter. Cultivation, whether done by wheel-hoe, hand-hoe, or weeder, should be shallow, never more than 2 inches deep, as the strawberry roots are near the surface and light cultivation of the surface soil does as much good as any other form. Weeds of all kinds should be

3731. The forcing of strawberries under glass.

kept down and comparatively little weeding will be necessary provided the ground is kept stirred.

During the summer at least three applications of fertilizer should be made, preferably before or during a rain. If the fertilizer mentioned previously cannot be obtained, bone-meal will give good results, particularly if wood-ashes are added.

If the season is particularly dry or the land is inclined to dry out rapidly, artificial watering may be practised, but it is better not to use water if it can be avoided. Plenty of cultivation will grow good plants on nearly all soils.

In the late fall after heavy frosts have come and the ground freezes slightly at night, it will be necessary to put some winter protection on the strawberry-bed. Many kinds of materials may be used, but first it is best to have a light mulch of well-rotted stable-manure scattered among the plants and worked under the foliage. Following this the winter protection may be put on. This should be of coarse hay, cornstalks, or very strawy manure, care being taken not to put on too much. A good rule to follow in placing a covering is that it must not be too close to prevent seeing some of the foliage of the strawberry plants under the mulch. The mulch may be held in place by brush, light cordwood or even soil, and in places where there is little snow great care must be taken to keep the mulch in place. It must be borne in mind that this careful protection is not to prevent the ground from freezing but rather to prevent the alternate freezing and thawing of unprotected ground in winter. In the spring as soon as danger from extreme frosts is past, the material for holding the mulch in place should be removed and also a part of the mulch itself, leaving some of the covering on the land to serve as protection to the fruit in the fruiting-season and to keep the soil moist. Some persons prefer to remove all the mulch and to cultivate the ground, and in some cases this is desirable; but, when the plants have had good culture the previous year it is just as well not to do much cultivating in the spring. Fertilizers should be added at this time, preferably bone-meal and wood-ashes mixed at the rate

of one-half pound of ashes to one pound of bone-meal and put on about one-eighth pound to the square foot.

If the weather is dry and the soil more or less inclined to dry out, water may be added at this time and up to the time the fruit is well set, being careful not to water during the daytime when the sun is shining. The question of watering strawberries is a very difficult one as so many conditions enter into the discussion. Some soils are naturally moist, and when water is added artificially to these, the tendency is for the plants to go to foliage or soft fruit or decayed berries. Too much water on a dry soil, particularly if added as the berries are coloring, is likely to injure the quality of the fruit while increasing the size, so that quality often is sacrificed to bulk. Generally speaking, in most seasons, if the land has been well cultivated the season before and the bed has been well mulched, there will be enough moisture in the land to carry the crop to maturity.

As quality in the strawberry depends very much upon ripeness and condition, it is well not to begin to pick too soon, but wait until the fruit has colored all over and has taken on the characteristic depth of tint which may be common to the variety. Be sure to pick the fruit early in the morning before the sun gets hot, keeping what berries are not used early in the day on ice. Pick the fruit with a stem; and for household use berries are much more attractive when picked in a shallow basket with some kind of foliage.

Within the past few years a new race of strawberries has been developed commonly called everbearing from their habit of producing fruit after the regular strawberry season has passed. This strain has now been permanently established and it is a great source of satisfaction to strawberry-lovers to have fruit after the regular season is over. There are several varieties of these everbearing strawberries, and every garden should have a few of them. They may be planted in any of the ways suggested for the regular varieties but they should have plenty of water during the summer to insure the full development of the fruit. In most locations in the northern states these varieties begin to ripen early in August and continue until heavy frosts. It is advisable to cut off the blossoms in May if a large crop is wanted in August, but they will fruit at both times after a short rest in July. Many of these varieties have a tendency to make too many plants and it is well to follow the same general directions as given for growing the standard varieties. Most of these everbearing varieties do very well in the usual hill culture.

WILFRID WHEELER.

Forcing of strawberries. (Figs. 3731, 3732.)

The forcing of strawberries for a winter crop has not as yet become of any great commercial importance in North America. Some gardeners grow a few potted plants for either Christmas or Easter decoration. Very few, if any, commercial growers are forcing strawberries exclusively to any profitable extent. The few strawberries that are forced are grown either in pots or planted out on benches. The former method is the one generally employed. There are several good reasons for this, some of which are: first, the confinement of the roots; second, the ability to ripen the crowns in the fall; third, the control of fertilizers and liquid manure; fourth, the privilege of having the crop grown in several houses at one time or brought from a coolhouse into heat; and fifth, the opportunity to supply particular demand of the potted plants or their fruits. The first expense of the pot method is considerably more than when the plants are grown in the benches, but after

the pots are once purchased the cost of each method should be about the same.

The pot method as practised at Cornell University is about as follows: As early in the spring as possible large plants are set in well-enriched soil. The first strong runners made by these plants are secured and potted. Numerous 2- or 3-inch pots filled with good soil are plunged to the rim along the strawberry row. The runners are trained to these pots, and a small stone is placed on each runner to keep it from growing beyond the pot. When the pot is filled with roots the young plant is cut from the parent stock, the pots lifted and taken to the potting-shed or other convenient place, where they are at once shifted into the fruiting-pots (usually a 6-inch pot). The soil used at this time should be three parts fibrous loam and one of good sharp sand. This potting-soil should have mixed with it bone-flour or dissolved rock at the rate of about one pint to two bushels of soil. Ample drainage should be given, as through the season of ripening the crowns and the following forcing-period, a large quantity of water must be given and none should be allowed to stand around the roots.

The pots should then be plunged to near the rim in some coarse material, preferably coal-ashes, which, if deep enough to extend from 4 to 6 inches below the plunged pots, will prevent the earthworms from entering the pots. The use of a frame in which to plunge the pots is recommended for protection against heavy rains or early frosts. Attention to watering is all that will be necessary through the growing season. Late in September or early in October the pots will be filled with roots and the plants will have attained their full growth. At this time larger and firmer crowns will be had by careful attention to watering and subsequent drying off to almost the wilting stage than by watering the plants up to the time of freezing weather. The drying process seems to represent the late fall season and causes the plant to store up material in the crowns at an earlier period. At the coming of cold weather the soil in the pots may be allowed to freeze. It is very desirable that the soil be on the dry side before freezing, for if the ball of earth is wet there is danger of breaking the pots when the cold becomes intense. The period of forcing,

3732. A good winter strawberry plant in bloom.

from the time the frozen plants are brought in until the ripening of the fruits, will be about eight weeks. The time will vary slightly under different conditions of heat and sunlight. When first brought in, the plants should be cleaned of all dead or diseased leaves. The pots should be plunged to near the rim in some material that will retain moisture, e. g., tanbark or coal-ashes. The benches or shelves should be as near the glass as convenient. A thorough spraying with bordeaux mix-

ture or some other fungicide should be made at once. For the first few days the house should be held at about 35°, with little if any rise through the day. After a week a rise of 10° may be given. At the end of the second week 50° at night, with a rise of 10° to 15° through the day, will be about right.

Strict attention must be given to syringing the foliage every pleasant day. Keep the walks wet until the time of blossoming. This moisture keeps down the red-spider. At blossoming time the house should be allowed to dry out, and a free circulation of air should be maintained through the middle of the day, in order to ripen the pollen. It is necessary to pollinate each flower by hand. The pollination may be done in the middle of the day while the houses are dry. A small camel-hair brush is useful for distributing the pollen. A ladle or spoon should also be provided in order to carry the surplus pollen. The surplus pollen may be used on varieties that are pistillate or do not have pollen enough to set their own fruits. Six to eight fruits are enough for a 6-inch pot. When these are set the remaining flowers should be cut off, in order that the entire strength of the plant may go to swelling the chosen fruits. After swelling begins, liquid manure should be given. During the first week give one dilute application. After this give two applications a week, increasing the strength of the manure liquid each time. Well-rotted cow-manure or sheep-droppings furnish good material for this purpose. When the fruits are coloring the liquid manure should be withheld and only clear water given. As they swell, the fruits will need support, and the best method of furnishing this is probably by using small-meshed window-screen wire cut into suitable squares. These squares may be laid on the pot, under the clusters of fruits. They hold the fruits away from the sides of the pots, protect them from any water or liquid manure that is given the plants, and enhance the beauty of the potted plant. After one fruiting, the plants are worthless.

C. E. HUNN.

STRAWBERRY BUSH: *Evonymus americana*. S. Geranium: *Saxifraga sarmentosa*. S.-Raspberry: *Rubus illecebrosus*. S. Tomato: *Physalis Alkekengi* and other species of *Physalis*. S. Tree: *Arbutus Unedo*.

STRELITZIA (for the wife of King George III, Charlotte Sophia, of the family Mecklinburgh-Strelitz, a patron of botany). *Musaceæ*. BIRD-OF-PARADISE FLOWER. Perennial herbs, adapted to the warmhouse, grown for the banana-like foliage and the very odd showy flowers.

Rhizome sometimes subterranean, sometimes an erect woody st.: lvs. large, long-petioled; scape terminal or in the upper axils, short-exserted from the sheaths of the lvs.: bracts large, spathe-like, boat-shaped, acuminate, solitary at the end of the scape or 2 slightly distant; perianth long-exserted; sepals free, long, carinate; petals very dissimilar; stamens 5; ovary 3-celled, many-seeded.—About 5 species, S. Afr. The genus has been monographed by K. Schumann in Engler's *Pflanzenreich*, hft. 1 (IV. 45) 1900.

The *Strelitzia Reginæ* requires a strong soil, a copious supply of water, and considerable sunlight. It is a serviceable plant for house decoration or for the porch or lawn in summer. It will endure much neglect, but unless well cared for it may fail to bloom regularly and well. A night temperature of 50° is sufficient. This plant may be induced to set seed if the flowers are hand-fertilized. The usual method of propagation, however, is by suckers and division.

A. Plant nearly stemless.

B. Lvs. ovate or ovate-oblong, margin crisped.

Reginæ, Banks. BIRD-OF-PARADISE FLOWER. Fig. 3733. About 3 ft. high; roots large, strong-growing; lvs. oblong, about 1 ft. long, stiff, concave; lf.-stalks all radical, 2-3 times as long as the lvs.; scape higher

than the lvs.: spathe about 6 in. long, nearly horizontal, purplish at the base, about 6-fld., the fls. orange and blue-purple. Winter. B.M. 119, 120. G.C. III. 54:86. Gn. 60, p. 412; 76, p. 168. Gn.W. 23:185. R.H. 1909: 308. Var. *citrina*, Hort., is cult. abroad. Gn. 78, p. 30.

BB. Lvs. linear-lanceolate, margin flat.

parvifolia, Dry., is at once distinguished by its linear-lanceolate lvs. with an equal base and flat margin. S. Afr.—The species is probably not cult. Var. *júncea*,

3733. *Strelitzia Reginae*. ($\times \frac{1}{4}$)

Andr. (*S. júncea*, Link), has lvs. with practically no blade: spathe green margined with magenta, sepals orange, petals rich blue, white-tipped. S. Afr. B.R. 516. R.B. 29, p. 184.

AA. Plants with finally tall woody sts.

B. Base of lvs. cordate: interior petals white.

angusta, Thunb. (*S. angusta*, D. Dietr.). Becoming 18 ft. high: lvs. at the summit of the st. 2–3 ft. long, oblong, acute; petiole 4–6 ft. long; peduncle short, from a leaf-axil: spathe deep purple: fls. on short purple pedicels, all parts of the fl. pure white; petals round at the base. B.M. 4167; 4168. G.C. III. 35:402.

kwéensis, Hort. (*S. angusta* $\times$ *S. Reginae*). Plant about 5 ft. high: lvs. as in *S. angusta* but the blades 2 $\times$ 1 $\frac{1}{4}$ ft.: fls. vertical, pale watery yellow, more resembling those of *S. Reginae*, but the small hooded petal is more like the other parent as are the lilac-pink patches at the base of the sepals. Garden hybrid. G.C. III. 47:217; 54:87.

BB. Base of lvs. obtuse: interior petals blue.

Nicolai, Regel & C. Koch. Resembling *S. angusta* in habit and foliage, but the fls. and spathe are much larger and the petals are hastately combined and blue in color. B.M. 7038. F.S. 13:1356. Gt. 7:235.

F. TRACY HUBBARD.†

STREPTOCALYX (*twisted calyx*). *Bromeliaceae*.

There are 7 species of *Streptocalyx*, according to Mez (DC. Monogr. Phaner., vol. 9), of Brazil. The genus differs from *Bromelia* in having strongly imbricated broad sepals and long corolla-tube. No species are in the American trade, but *S. Fürstenbergii*, Morr., is described in horticultural literature (sometimes as *Æchmea Fürstenbergii*, Morr. & Wittm.). It is a stemless pineapple-like plant, with 30–40 rigid lanceolate lvs. in a dense rosette: cluster a central dense panicle 1–1 $\frac{1}{2}$ ft. long, with many 2-sided spikes of rather dull fls. *S. longifolius*, Baker (*Bromelia longifolia*, Rudge), has densely rosulate lvs. 3–6 ft. long, vaginate at base, spinulose at apex and margin, dark-colored on the edges, scaly. Guiana.

STREPTOCARPUS (Greek compound, meaning *twisted fruit*). *Gesneriaceae*. CAPE PRIMROSE. Herbs, frequently villous or lanate, adapted to greenhouse culture; choice plants, grown for the showy bloom.

Stemless, with 1 or more spreading radical lvs. or rarely with a st. and opposite lvs.: peduncles scape-like or axillary, sometimes 1–2-fld., sometimes cymose, several-fld.: fls. pale purple or blue, showy; calyx 5-parted; corolla-tube elongated, cylindrical or spreading above, limb obliquely 2-lipped, posterior lip 2-cleft, anterior larger, 3-cleft; perfect stamens 2; disk short-annular; ovary superior, imperfectly 4-celled: caps. linear, terete, splitting in 2, rarely 4 valves.—About 60 species, natives of S. Afr. and Madagascar. In Oct., 1826, there bloomed at Kew a most interesting gloxinia-like little plant, seeds and specimens of which had been collected in S. Afr. by Bowie, on the estate of George Rex, at Knysna. The plant was described as *Didymocarpus Rexii*. It is a stemless plant, with 1 or rarely 2 long-tubular nodding pale blue fls. on each of several short scapes, and with several clustered root-lvs. It proved to be a profuse bloomer and easy to grow. "So abundantly does it produce seed," wrote W. J. Hooker, in 1830, "that new individuals come up as weeds in the neighboring pots, and a succession of flowers may be obtained at almost every period of the year." In 1828, John Lindley made the genus *Streptocarpus* for this plant, calling it *S. Rexii*, the name it now bears. It appears to have been nearly thirty years after the intro. of *S. Rexii* that another streptocarpus bloomed in England. This second species was *S. polyanthus*, which may be taken as the type of a group that has one leaf lying on the ground and from the midrib of which arise successive several-fld. scapes. The intro. of this curious plant seems to have revived the interest in streptocarpaceae, an interest that has been kept alive by the frequent intro. of other species. The chief stimulus to the systematic breeding of these plants seems to have been the intro. of *S. Dunnii*, said by J. D. Hooker to be "quite the monarch of its beautiful genus" (but now excelled by *S. Wendlandii*). Seeds of this species were sent to Kew in 1884 by E. G. Dunn, of Cape Town. It is one of the monophyllous section to which *S. polyanthus* belongs. In the meantime, *S. parviflorus*, a species allied to *S. Rexii*, had been intro. from the Cape region. With the three species, *S. Rexii*, *S. parviflorus*, and *S. Dunnii*, Wm. Watson of the Royal Gardens, Kew, set to work systematically to breed a new race of streptocarpus, and his efforts met with unequalled success. When the hybrids came to notice in 1887, the Gardener's Chronicle made the following comment on the value of the work: "The results are very striking, and we can hardly doubt that Mr. Watson has set the foundation of a new race of plants, parallel in importance to the *Achimenes* and *Tydas*." Several hybrid races have now been produced and several interesting species have been intro. from the wild, so that *Streptocarpus* seems to be destined to become a very important and popular garden genus.

Bentham and Hooker's treatment divides the *Ges-*

neriaceæ into two great tribes: Gesnereæ, with ovary more or less inferior and fruit a capsule; Cyrtandrea, with ovary superior and fruit sometimes a berry. The latter tribe, the species of which have been monographed by C. B. Clarke in vol. V of DeCandolle's "Monographiæ Phanerogamarum," contains the genera Streptocarpus, Episcia, Cyrtandra, Æschynanthus, Ramondia, and others. Streptocarpaceæ are of three groups: the stemless monophyllous species, with one prostrate leaf from the midrib of which the scapes arise (this leaf is really an enlarged cotyledon, the other cotyledon not enlarging); the stemless species, with several or many radical more or less primula-like leaves (whence the English name "Cape primrose"); the stem-bearing species, with opposite cauline leaves. The cultivated species chiefly represent the first two sections. In the American trade, four specific names chiefly occur, *S. Rexii*, *S. Galpinii*, *S. Dunnii*, and *S. Wendlandii*; but since the hybrids represent several other species, these additional species are inserted in the following account. Streptocarpus is an African genus. The stem-bearing section is confined to central Africa and Madagascar, and the others to South Africa. Clarke's monograph, 1883, describes nineteen species, but *S. Dunnii*, *S. Wendlandii*, *S. Galpinii*, and many others have since been discovered.

Streptocarpaceæ are not difficult plants to grow. They are usually raised from seeds, the seedlings blooming in eight to fifteen months from starting. The seeds are very small, and care must be taken not to cover them too deep. Give an open sunny place in an intermediate temperature. They are not stove or greenhouse plants. Of the new hybrid forms, seeds sown in February or March should produce plants that will bloom the following fall and winter; after blooming, the plants may be discarded, for better results are usually secured from new plants than from those more than one season old. The season of most profuse bloom is summer, but the bloom continues until winter. The monophyllous species can be propagated also by cuttings of the leaf. Some fanciers of Cape primroses advise propagating select types by leaf-cuttings or by division.

KEY TO THE SECTIONS.

- A. Plants of native origin.
 - B. Sts. elongated: lvs. opposite.
 - Section I. CAULESCENTES. Species 1.
 - BB. Sts. lacking or very short: lvs. all radical.
 - c. Lvs. several, forming a rosette.
 - Section II. ROSULATI. Species 2-6.
 - CC. Lvs. solitary.
 - Section III. UNIFOLIATI. Species 7-12.
- AA. Plants of hybrid origin.
 - Section IV. HYBRIDA. Species 13-17.

Section I. CAULESCENTES.

1. *caulescens*, Vatke. Caulescent, hirsute: lvs. long-petioled, oval-oblong, entire, rather repand, apiculate, obtuse, base contracted to the petiole, puberulent above, villous beneath: fls. blue, $\frac{1}{2}$ in. across; calyx hirtellous, lobes linear; corolla up to nearly $\frac{3}{4}$ in. long, 6 times longer than the calyx, limb strongly unequal. Trop. Afr. B.M. 6814.

Section II. ROSULATI.

- A. Scapes 1-2-fld.
 - B. Fls. blue or mauve. 2. *Rexii*
 - BB. Fls. pale lavender to rosy pink or rosy mauve. 3. *cyaneus*
- AA. Scapes 3- to many-fld.
 - B. Corolla-tube cylindric, nearly straight, limb slightly 1-sided.
 - c. Lvs. not decurrent on the petiole. 4. *parviflorus*
 - cc. Lvs. attenuated into the petiole. 5. *luteus*
 - BB. Corolla-tube much curved, limb very oblique. 6. *Junodii*

2. *Rexii*, Lindl. (*S. Gardenii*, Hook.). Fig. 3734. Acaulescent: lvs. several, suberect, 8 x 2 in., oblong, crenate, hairy on both surfaces: scapes several, 4-12 in. high, 2-1-fld.: calyx-lobes narrowly oblong, hairy; corolla 2 in. long, about as wide, blue or mauve, tube $1\frac{1}{3}$ in. long, very narrowly linear-funnel-shaped, lobes a little unequal. S. Afr. B.M. 3005; 4862. B.R. 1173. L.B.C. 14:1305. F.S. 12:1214. Var. *biflorus*, Ortgies, differs in having stouter 2-fld. scapes. Gt. 6:204.

3. *cyaneus*, S. Moore. St. prostrate, slightly elongated, bearing 4 lvs.: lvs. linear-oblancoate, narrowed below the middle into a narrow petiole-like portion, apex obtuse: scape always 2-fld.: fls. varying from pale lavender or blue to rose-pink or rosy mauve, with a few streaks of red on the 3 lower lobes and a blotch of yellow in the throat; calyx-lobes linear-oblong, pilose-pubescent; corolla about $1\frac{1}{4}$ in. long, puberulent outside. Transvaal. B.M. 8521. G.C. III. 55:31.—Allied to *S. Rexii*.

4. *parviflorus*, Mey. Acaulescent: lvs. several, spreading or suberect, nearly or quite sessile, elliptic, up to 9 x 3½ in., crenate and bullate, shaggy, dark green above, nearly white beneath: scapes several, 6-10 in. high, reddish, shaggy, bearing 3-10-fld. cymes: fls. about $\frac{3}{4}$ in. across; calyx glandular-pubescent, lobes narrowly oblong; corolla-tube glandular-pubescent, $\frac{2}{3}$ - $\frac{3}{4}$ in. long, cylindrical, obscurely widened upward, purplish outside, mouth a little oblique, lobes orbicular, white. S. Afr. B.M. 7036.

5. *luteus*, C. B. Clarke. Lvs. several, petioled, elongate-oblong, 8-13 x 2-2¾ in., obtuse, attenuate at base, crenate, villous on both surfaces, almost tomentose beneath: peduncles and fls. almost as in *S. parviflorus*: corolla shorter, white, throat yellow, or almost white penciled with purple, tube slightly widened upward: caps. densely silky. S. Afr. B.M. 6636 (as *S. parviflorus*).

6. *Junodii*, Beauverd. Acaulescent, caespitose: lvs. 4-6, rugose, base attenuate, villous, veins prominent beneath: peduncles erect from the lf.-axils, pilose, 3-4½ in. high: fls. 3-6, pendulous, blue-lilac; calyx 5-parted, segms. unequal, linear, recurved; corolla hirsute outside, 1½-2 in. long, arched, limb 5-lobed,

oblique, lobes rotund, the lower yellow-blotched at base. S. Afr.

Section III. UNIFOLIATI.

- A. Corolla-tube broader than long..... 7. *Galpinii*
 AA. Corolla-tube longer than broad.
 B. Fls. rose to reddish..... 8. *Dunnii*
 BB. Fls. bluish or purplish.
 C. Tube of corolla linear-cylindrical... 9. *polyanthus*
 CC. Tube of corolla more or less widened at the mouth.
 D. Limb of corolla much shorter than the tube10. *grandis*
 DD. Limb of corolla nearly as long as the tube.
 E. Lf. rarely over 1 ft. long; corolla usually less than 1 in. across.....11. *Saundersii*
 EE. Lf. usually much over 1 ft. long; corolla usually more than 1¼ in. across.....12. *Wendlandii*

7. *Galpinii*, Hook. f. Acaulescent: lf. solitary, sessile, ovate-oblong, obtuse, very entire, base subcordate, silky-villous above, fleshy nerves which are strongly red beneath: scapes several, they and the pedicels densely glandular-pubescent: fls. racemose, on stout erect or spreading pedicels, violet; calyx-segms. linear, obtuse; corolla campanulate, tube slightly incurved, lobes 5, equal, spreading-recurved, orbiculate. Transvaal. B.M. 7230. J.H. III. 23:389. G.C. III. 11:139.

8. *Dunnii*, Mast. Fig. 3735. Acaulescent, soft glandular-pubescent or tomentose: lf. solitary, very large, 2-3 ft. long, sessile, ovate-oblong, obtuse, margin irregularly lobulate and crenate, bullate between the reticulate veins, midrib thick and villous beneath: scapes very numerous, clustered, produced serially, stout, 1 ft. or more high, bearing many-fld., secund panicles: fls. 1½ in. long, pale brick-color to rose, short-pedicelled, inclined or nodding; calyx-segms. linear-oblong; corolla curved, tubular-funnel-shaped, puberulent, lobes short rotund, ciliolate. S. Afr. B.M. 6903. G.F. 3:609 (adapted in Fig. 3735).—A plant sometimes produces more than 100 fls.

9. *polyanthus*, Hook. Acaulescent: lf. solitary, 5-7 x 3 in., round or elliptic, obscurely crenate, hairy on both surfaces: scapes 1-3, up to a foot or more high, rather stout, 4-10-fld.: calyx hairy, teeth linear; corolla pale blue, about 1¼ in. across, tube linear-cylindrical, curved, limb unequal, the 3-lobed lip much longer than the 2 upper segms. S. Afr. B.M. 4850. Gt. 6:206.

3735. *Streptocarpus Dunnii*. (X about ¼)

R.H. 1862, p. 250; 1889, p. 398; 1896, p. 12. Var. *grandiflorus*, Hort., is a large-fld. form. H.F. II. 1:128.—Said to be a garden hybrid.

10. *grandis*, N. E. Br. Acaulescent: lf. solitary, radical, 2-3½ ft. long, 1-2¼ ft. broad, ovate, base cordate, crenate, pubescent on both sides; cauline lvs. none or few, small, ovate, sessile: peduncles several,

3736. *Streptocarpus Wendlandii*. (X ¼)

1½-3½ ft. high, bearing above 2-6 lax racemes, pubescent: fls. in 2's, lavender or light blue outside, white within, marked with 2 broad lilac stripes in the throat; corolla-tube about 1 in. long, bent downward, upper lobes pale blue or lavender. Zululand. B.M. 8042.

11. *Saundersii*, Hook. Acaulescent: lf. solitary, sessile, flat on the ground, 14 x 12 in., very broadly elliptic, short-hairy on both surfaces, crenate, yellowish green above, purple-rose beneath: scapes 1-5 from the axil, 10-18 in. high, sometimes bearing a small lf. near the base; cyme repeatedly divided, 40-80-fld.: calyx-lobes narrow-oblong, hairy; corolla pale blue with purple blotches in the throat, tube somewhat funnel-shaped, a little curved, limb oblique, 2 lobes much shorter. S. Afr. B.M. 5251. F.S. 17:1802. Gt. 24:826.

12. *Wendlandii*, Sprenger. Fig. 3736. Acaulescent: lf. solitary, attaining a size of 30 x 24 in., crenate, closely hairy, red-purple beneath: scapes several, 1-2½ ft. high, forked; infl. 6-8 in. long, 30-fld.: calyx-lobes linear, hairy; corolla violet-blue, tube about 1 in. long, slightly curved, limb 1½ in. across, oblique, lobes broad and entire. S. Afr. B.M. 7447 (part of which is copied in Fig. 3736). G.C. III. 22:275. Gn. 45, p. 511; 50, p. 394. J.H. III. 28:223. G. 17:181.—One of the finest species in cult.

Section IV. HYBRIDA.

(For colored pictures of modern hybrid types, see Gn. 29:545; 41:843; 50:1092.)

13. *achimeniiflorus*, Hort. Acaulescent: lvs. several, radiating or opposite, rather elliptical, somewhat fleshy, brilliant light green: fl.-st. stiff, most often 1-fld.: fl. as large as a gloxinia, but with the corolla divisions more deeply cleft, and finely dentate, bright lilac tinted with marine blue through pale lilac to pure white, the lower part of the corolla is always striped with deeper color. Possibly a garden hybrid. R.H. 1906, p. 309. Var. *albus*, Hort., is offered in the trade as a large-fld. white form. Var. *giganteus*, Hort., is offered as a lavender-blue form. Var. *roseus*, Hort., is offered as a soft delicate rose form.

14. *Bruantii*, Hort. (*S. Rexii* x *S. polyanthus*). Lvs. very large, not cordate, very velvety, bright green: scapes up to 14 in. high: fls. about double the size of

those of *S. polyanthus*, about $1\frac{1}{2}$ in. long, blue or bright mauve, throat yellowish white. Garden hybrid.

15. *Dyeri*, W. Wats. (*S. Wendlandii* × *S. Dunnii*). Acaulescent: lf. solitary, $2 \times 1\frac{1}{4}$ ft., rich olive-green above, vinous purple beneath, soft-hairy: fl.-st. 1-2 ft. high, several from a lf.: fls. numerous, long-tubular, bright red-purple. A garden hybrid.

3737. *Streptocarpus kewensis*. ($\times \frac{1}{2}$)

16. *kewensis*, Hort. (*S. Rexii* × *S. Dunnii*). Fig. 3737. Lvs. 2 or 3, large, but not so large as those of *S. Dunnii*, oblong or elongate-ovate, bright green: fl.-sts. numerous, each 6-8-fld., forming a tolerably compact mass: fls. bright mauve-purple, striped with dark brownish purple in their throat; corolla about 2 in. long, $1\frac{1}{4}$ - $1\frac{1}{2}$ in. across. Garden hybrid.

17. *Watsonii*, N. E. Br. (*S. luteus* × *S. Dunnii*). Lf. solitary, similar to but smaller than that of *S. kewensis*: scapes several, bearing 10-16 fls. each: fls. about $1\frac{1}{4}$ in. long and 1 in. across, bright rose-purple, with a white throat, which is striped with brownish purple. Garden hybrid. G.C. III. 2:215.

The following species are either little known or have not found their way into general cult.: *S. Armitagei*, Baker & Moore, is closely allied to *S. Dunnii*, differing in having a corolla much less funnel-shaped and straighter, with less spreading lobes; originally described as solitary-lyd., but 4 lvs. are said to have developed in the cult. plant. S. Afr.—*S. Banksii*, Lynch (*S. Wendlandii* × some hybrid), has 2 lvs. about 19×13 in. for the lower, the second somewhat smaller: fls. large, purple-blue. Garden hybrid. G.C. III. 56:192.—*S. biflorus*, Pucci, is a name appearing in horticultural journals for some unknown plant, which is said to have several blue fls.—*S. bifloro-polyanthus*, Duch., is a hybrid, the female parent of which is *S. polyanthus*, the male the above-mentioned *S. biflorus*: it is said to have 5 ovate-oblong, crenate, rugose lvs.; several scapes with 2-4 pale lilac fls. F.S. 23:2429.—*S. Blythinii*, Lynch (*S. Wendlandii* × *S. cyaneus*), has 2-5 lvs., the largest of which is 15×9 in. and another is 12×7 in., green beneath, in some cases reddish toward the tip, in others with the color here and there: scapes 9-10, each with 5-14 fls., about 14 in. high: fls. about $1\frac{1}{2}$ in. across, lavender or bluish purple; petals marked with dark purple stripes. Garden hybrid. G.C. III. 56:260.—*S. cantabrigiensis*, Lynch (*S. cyaneus* × *S. Dunnii*), has several lvs. which are $7-8 \times 3$ in.: scapes about 7 in. high, 2-12-fld., conspicuously hairy: calyx-segms. linear-lanceolate; corolla 2 in. long, about $1\frac{1}{2}$ in. across, tube funnel-shaped, lobes rounded, throat white with 7 deeply colored lines, limb deep rose. Garden hybrid. G.C. III. 59:131.—*S. Gaudinii*, Hort., is offered in the trade.—*S. Greenii*, Hort. ex Wilson (*S. Saundersii* × *S. Rexii*), is dwarfier and more compact than the former parent, the scapes many-fld.: fls. pale lilac-blue. Garden hybrid. G.C. II. 17:303. Said to be the first hybrid streptocarpus.—*S. Holstii*, Engl., resembles *S. caulescens*; plant about $1\frac{1}{2}$ ft. high, producing a large number of sts., each bearing 6-8 dark violet-blue fls. $\frac{3}{4}$ -1 in. long, spotted with white on the midlobe of the lower lip. German E. Afr. (Section I.) B.M. 8150.—*S. hybridus*, Hort., is a name applied to garden hybrids in general.—*S. Kirkii*, Hook. f. Caulescent; st. 4-6 in. high, stout, erect, hairy: lvs. 1-2 in. long, broadly ovate, obtuse, crenate, finely pubescent on both surfaces, base rounded or cordate; petiole $\frac{1}{2}$ - $\frac{3}{4}$ in. long: scapes axillary, very slender, 3-4 in. high: fls. drooping, opposite; calyx-lobes lanceolate, pubescent; corolla $\frac{3}{4}$ in. long, pale lilac, tube hairy, upcurved, broad and subcampanulate, mouth expanded, lobes short rounded,

ciliate. Trop. E. Afr. B.M. 6782. (Section I.) Allied to *S. caulescens*.—*S. lichtensteinensis*, Hort. (*S. Wendlandii* × *S. Watsonii*), has 2 lvs., 1 prostrate and the other smaller and erect: fls. numerous, lilac-blue. Garden hybrid.—*S. Mahonii*, Hook. f. Acaulescent: lf. solitary, 1 ft. or more long, flat on the ground, sessile, ovate-oblong, crenulate, tip rounded, base cordate: scapes many, crowded, densely pilose: fls. long-pedicelled; calyx-segms. pubescent, linear, corolla violet, tube $\frac{3}{4}$ in. long, pubescent, decurved, somewhat inflated above; lobes rotundate. Brit. Cent. Afr. B.M. 7857.—*S. multiflora*, Laing., is a seedling of *S. Rexii*, with up to 30 large bluish purple fls., which have darker purple lines in the throat and running up onto the lower lip. Garden hybrid. G.C. III. 18:211; 32:327. I.H. 43, p. 67.—*S. orientalis*, Craib. Caulescent; st. solitary, erect, simple, 6-16 in. high, leafy: lvs. ovate to elliptic-ovate, apex obtuse, base cuneate, crenate or crenate-serrate, $1-3\frac{1}{2} \times \frac{3}{4}-2\frac{3}{4}$ in., both surfaces glandular-pilose; petioles up to 2 in. long: infl. axillary, cymose: calyx-lobes lanceolate or linear-lanceolate, white-glandular-hairy outside; corolla purple outside, paler within, tube over 1 in. long, limb about $\frac{3}{4}$ in. across, lobes reflexed-spreading, wide oblong, tip rounded. Siam. B.M. 8526.—*S. Veitchii*, Hort., is offered in the trade.

F. TRACY HUBBARD.†

STRÉPTOPUS (Greek, *twisted stalk*, referring to the peduncles). *Liliaceae*. **TWISTED STALK**. Perennial herbs, with the aspect of *Polygonatum*, hardy and adapted to the wild-garden; should be grown in shade or with rich, loose, and moist soil in sunlight.

Stems erect from a short dense, or longer, repent rhizome, simple or slightly branched: lvs. alternate, ovate or lanceolate, membranaceous, sessile or clasping: fls. medium-sized, solitary or paired in the axils, nodding, rose or whitish; perianth campanulate, segms. distinct or connate at base; stamens 6; style 3-cleft; ovary sessile, ovoid, 3-celled: berry subglobose, indehiscent.—About 6 species, Eu., Temp. Asia, and N. Amer. Woodland plants closely related to *Disporum* which has terminal fls.

A. Fls. purple or rose.

roseus, Michx. Fig. 3738. Rootstock short, stout: st. 1-2 ft. high: lvs. sessile, only partially clasping, 2-4 in. long: peduncles less than 1 in. long, mostly 1-fld.: fls. about $\frac{1}{2}$ in. long: berry red, $\frac{1}{2}$ in. thick. May-July. Moist, rich woods in the northern states, S. to Ga.

3738. *Streptopus roseus*. ($\times \frac{1}{2}$)

AA. Fls. greenish white.

amplexifolius, DC. Rootstock short, stout: st. usually taller than *S. roseus*: lvs. clasping, 3-6 in. long: peduncles 1-2 in. long, usually 2-fld.: fls. about $\frac{1}{2}$ in. long: berry red. May-July. Moist rich woods, N. U. S. and Canada south to N. C. and New Mex.; also in Eurasia.

F. W. BARCLAY.

STREPTOSOLEN (Greek, *streptos*, twisted, *solen*, tube, with reference to the form of the corolla-tube). *Solanaceae*. Scabrous-pubescent shrub, suitable for greenhouse culture and for outdoors, as an ornamental, in the extreme S. Lvs. entire, not large, rugose: fls. orange-red, pedicelled, in a terminal corymbose panicle; calyx tubular-campanulate, shortly 5-cleft; corolla-tube elongated, spirally twisted below, widening above, limb spreading, 5-lobed, lobes broad, very obtuse; perfect stamens 4, didynamous; ovary stipitate, 2-celled: caps. somewhat leathery, valves 2-cleft.—One species, Colombia.

Jamesonii, Miers (*Browallia Jamesonii*, Hort., & Benth.?). Fig. 3739. Handsome evergreen scabrous-pubescent shrub, 4–6 ft. high, hardy and much cult. in Calif. as far north as San Francisco. June. G.C. II. 21:797. Gn. 26:6. R.H. 1833:36. B.M. 4605. F.S. 5:436. P.M. 16:6. G.M. 39:200. V. 7:298; 9:147.—An old favorite in northern greenhouses. F. TRACY HUBBARD.†

STRICKLÁNDIA (named in honor of Sir C. W. Strickland). *Amaryllidaceae*. Perianth narrowly funnellform, tube short, segms. oblanceolate, equal; stamens not declinate, filaments united half-way up in a cup, lanceolate above it, without any teeth between; ovary globose, 3-lobed, 3-celled: caps. short, deeply 3-lobed, loculicidally 3-valved; seeds many, small. One species, Andes of Ecuador. *S. eucrosioides*, Baker (*Leperiza eucrosioides*, Baker. *Phædranassa eucrosioides*, Benth. & Hook. f. *Stenómesson Stricklandi*, Baker). Bulb ovoid, 2 in. diam.; tunics brown, membranaceous: lvs. 2 to a st., produced after the fls., thin, green, oblong, 6–9 in. long; peduncle slender, terete, 1 ft. high: fls. 3–4 in an umbel, horizontal or cernuous; spathe-valves linear; perianth-tube green, lobes red, laxly nerved, not keeled nor tipped with green. Andes of Ecuador. G.C. III. 30:263. Cult. as for *Phædranassa*.

STROBILÁNTHES (Greek, *cone* and *flower*, referring to the inflorescence). *Acanthaceae*. Herbs or shrubs, erect, sometimes tall, glabrous, scabrous-pubescent or villous; greenhouse, or out-of-doors in extreme South.

Leaves opposite, in a few species strongly separated, entire or toothed: fls. blue, violet, or white, rarely yellow, solitary at the axils of the opposite bracts, sessile or short-pedicelled, sometimes in dense or interrupted terminal spikes or the peduncles clustered at the axils; calyx deeply 5-cleft or almost 5-parted, segms. linear; corolla-tube slender at the base, widened above; limb spreading, 5-lobed, lobes ovate; perfect stamens 4 or 2: caps. oblong or linear, 2-celled at or near the base.—About 200 species, India, Malaya, China, and Japan, also 1 in Trop. Afr. Adapted to the warmhouse.

Strobilanthes are mostly erect half-shrubby plants cultivated for their flowers and foliage. Only young, well-grown plants are attractive, the older ones becoming weedy and unattractive. Some species are grown as ornamental foliage bedding plants, but they are not so

desirable for general use as the coleus, the slightest cool weather changing the color of their leaves to a very undesirable shade. In the greenhouse they make fine decorative foliage plants but require at all times a high temperature and an abundance of moisture and much syringing. Under unfavorable conditions they lose their leaves and become unsightly.

3739. *Streptosolen Jamesonii*. ($\times \frac{1}{2}$)

anisophyllus, T. Anders. (*Goldfussia anisophylla*, Nees). Branches somewhat zigzag: lvs. broadly lanceolate, acuminate, serrulate, opposite, but one of each pair much smaller than the other: fls. purplish and white; corolla funnel-shaped, very broad at the mouth, with a somewhat irregular 5-lobed limb. India. B.M. 3404. R.B. 955 (as *Ruellia persicifolia*). R.B. 29:36.—Similar to *S. isophyllus* in habit and use.

callösus, Nees. Shrub, 6–8 ft. high: lvs. elliptic-lanceolate, acuminate, puberulous, narrowed into a long, slender petiole which is winged to the middle: fls. in short, oblong spikes, large, pale violet-blue; corolla-tube very short, dilated into a subcampanulate throat and expanding into a limb 2 in. across; lobes orbicular, undulate. B.M. 7538.—A native of W. India, where it forms a shrub 6–8 ft. high; said to flower in its third year.

Dyerianus, Mast. An erect, branching, soft-wooded stove shrub: st. hirsute: lvs. opposite, 6–8 in. long, elliptic-lanceolate, serrulate, cordate at base, sessile, variegated with iridescent tints of blue and lilac, rose-purple beneath: fls. in erect spikes, $1\frac{1}{2}$ in. long, pale violet; calyx unequally 5-lobed, lobes linear, obtuse; corolla-tube curved, ventricose, limb of 5 short, broad, revolute lobes. Burma. B.M. 7574. R.B. 20:133. J.H. III. 26:359. A.G. 17:297. V. 19:67. G.M. 46:149.—Used for bedding.

gossypinus, T. Anders. Shrubby, covered with dense yellowish wool: lvs. 4 x 2 in., ovate, acute, base broad-rhomboid, subcoriaceous, entire, wool of upper surface deciduous: spikes 1–3 in. long, linear-oblong, woolly, compound, becoming paniculate: fls. violet; calyx-segms. narrowly lanceolate; corolla nearly straight. India. B.M. 7790. G.M. 56:958.

isophyllus, T. Anders. (*Goldfussia isophylla*, Nees). A low, much-branched, bushy shrub, 2–3 ft. high, swollen at the joints: lvs. short-petioled, opposite, narrowly lanceolate, distantly serrulate or entire: peduncles axillary, shorter than the lvs., bearing several fls.: corolla 1 in. long, funnel-shaped, blue and white; limb 5-lobed; lobes emarginate. India. B.M. 4363. B. 5:244.—Used either for bedding or for pots. Blooms profusely either in winter or summer, according to treatment.

Micholitzii, Ridley. Subshrub, 3–4 ft. high: st. 4-angled, dilated at the nodes: lvs. lanceolate or ovate-lanceolate, 6 x 2 in., one of the pair much larger than the other, acuminate at both ends: racemes axillary, very numerous, cone-like, $\frac{1}{2}$ – $\frac{3}{4}$ in. long; bracts rounded, white, tipped with green: fls. white, projecting slightly from the cone. Sumatra.

S. auriculatus, Nees. Shrub, 2–6 ft. high, glabrous, except the more or less hairy tips of the branches: lvs., one sometimes 10 x 2 $\frac{1}{2}$ in., the other 3 x 1 $\frac{1}{2}$ in., ovate, serrulate: spikes terminal, solitary: fls. pale purple. India. H.U. 6, p. 196.—*S. glomeratus*, T. Anders. Shrub, with branches often horizontal and hairy upward: lvs. ovate and acute, complanate (flattened), serrate, hairy or villous above: fls. purple, about 2 in. long. India. B.M. 3881 (as *Goldfussia glomerata*).—*S. Wallichii*, Nees. Weak subalpine shrub with angled branches: lvs. elliptic, acuminate: fls. blue, in pairs or solitary. Himalaya. B.M. 5119 (as *Goldfussia Thomsoni*).

HEINRICH HASSELBRING.
F. TRACY HUBBARD.†

STROMÁNTHE (Greek, *couch and flower*; said to allude to the form of inflorescence). *Marantaceae*. Perennial herbs grown in the warmhouse for the foliage.

Stems leafy, erect, from a thick horizontal rhizome, somewhat branched, the base covered by the long lvsheaths: lvs. short-petioled; infl. rather lax, terminal on a long peduncle, more or less compound, rarely narrow, almost raceme-like, frequently all colored blood-red; bracts and bractlets spathe-like, colored; sepals 3, free, oval-oblong; petals 3, slightly narrower than the sepals; ovary 1-celled, 1-ovuled: fr. subglobose.—About 12 species, S. Amer. (Schumann, in Engler's *Das Pflanzenreich*, hft. 11.—IV. 48). Closely allied to *Calathea*, *Maranta*, *Phrynium* and *Thalia*. It agrees with *Maranta* and *Thalia* in having a 1-loculed caps., and thereby differs from *Calathea* and *Phrynium*, which have 3 locules. From *Maranta* it differs in having a very short perianth-tube and the segms. not standing opposite each other. From *Thalia* it differs, as does *Maranta*, in having 2 side staminodia rather than 1. For cult., see remarks under *Calathea*.

Porteana, Griseb. (*Maranta Porteana*, Koern.). Two to 4 ft. high, with maranta-like lvs., the blades long-elliptic or ovate-lanceolate, varying from acuminate to almost obtuse, purple beneath, bright green above with transverse stripes or bars of silvery white: fls. solitary or twin on the rachis, blood-red, the infl. simple or compound. Brazil. Lowe 26.

sanguinea, Sonder (*Thalia sanguinea*, Lem.). Lf-blades about 1 ft. long, oblong-acuminate, purple beneath and green above: scape 12–20 in. tall, red toward the top, bearing a panicle of bright red and red-bracted fls. Probably Brazilian. B.M. 4646 (as *Phrynium*). F.S. 8:785. J.F. 3:268; 4:401.—An old garden plant. Thrives in an intermediate house and attains a height of 5 ft. when planted in a border. Var. *spectabilis*, Eichler (*S. spectabilis*, Lem. *Maranta spectabilis*, Koern.). Lvs. particolored with green beneath. L. H. B.

STRONGYLÔDON (Greek, *round and tooth*; the lobes of the calyx are rounded). *Leguminosae*. Glabrous twining shrubs or subshrubs: lvs. pinnately 3-foliate, stippled; stipules small: fls. red, showy, fasciculate racemose on elongated, axillary peduncles; calyx-teeth broad, obtuse; standard ovate-oblong, acute, recurved, finally reflexed, 2-appendaged inside above the claw; wings shorter than the standard and adherent to the keel which is beaked, strongly incurved, equaling the standard and connate with the petals; stamens free from the standard; ovary stipitate, 1- or few-ovuled: legume stipitate, obliquely ovate-oblong, 2-valved.—About 20 species, Madagascar, Ceylon, to N. Austral. and the Pacific islands. May be planted far S.

pseudolucidus, Craib. Climbing shrub: lvs. 3-foliate, nearly 5 in. long; lfts. more or less ovate, $3\frac{1}{2} \times 2\frac{1}{4}$ in.: racemes axillary, up to 3 in. long: fls. bright red, about 1 in. long. Madagascar, Ceylon, N. Austral. B.M. 8494.

STROPHÁNTHUS (Greek, *twisted cord and flower*, alluding to the corolla-segms.). Incl. *Roupellia*. *Apocynaceae*. Shrubs, often scandent, glabrous or more or less hairy, with persistent or deciduous foliage, suitable for the warmhouse: lvs. opposite, rarely ternate: infl. terminal, often at the ends of short branches, corymbose, many- or few-fl'd. or reduced to solitary fls.: fls. mostly showy; sepals 5, imbricate, sometimes foliaceous; corolla funnelform or campanulate, tube cylindrical, long or short, mouth with paired appendages alternating with the lobes which are 5, acuminate and produced into very long filiform tails; disk none: mericarps 2, follicular, oblong or fusiform, divaricate.—About 40 species, Trop. and S. Afr. and Trop. Asia.

S. dichotomus, DC. Erect shrub with stout branches: lvs. elliptic-oblong or obovate, $3-5\frac{1}{2} \times 2-3$ in., obtuse, acute or apiculate, rather coriaceous: cymes much shorter than the lvs., dichotomous,

few-fl'd.: sepals subulate from an ovate base; corolla-tube and throat $\frac{3}{4}$ –1 in. long, whitish tails 5–7 in. long, purple: follicles very large, 8×2 in., divergent. India, Malaya, and Java. H.U. 2, p. 225.

—*S. grandiflorus*, Stapf (*S. Petersianus* var. *grandiflorus*, N. E. Br.). Dense shrub, 5–6 ft. high, with long, slender, reddish brown branches: lvs. ovate to elliptic-oblong, shortly acuminate, $2-3 \times \frac{1}{2}$ –1 in., membranous: cymes terminal on leafy branches, usually reduced to a single fl.: sepals oblong to lanceolate-oblong, erect; corolla wide, purplish without, milk-white or creamy within, the lobes ovate, produced to filiform tails about 6 in. long. Trop. and S. Afr. B.M. 7390.—*S. gratus*, Franch. (*Roupellia grata*, Wall. & Hook.). Small glabrous tree or shrub: lvs. oblong, short-acuminate, base obtuse or subacute, leathery: cymes terminal, sessile, few- to 12-fl'd.: fls. white or tinged with pink, large; sepals broad, oblong or obovate; corolla-tube $1\frac{1}{2}$ in. long, lobes broad, obovate, $\frac{3}{4}$ –1 in. long; ovary glabrous: follicles obtusely acuminate. Trop. Afr. B.M. 4466. G.C. III. 28:151. J.F. 1:16.—*S. Ledienii*, Stein. Shrub, with softly and sparingly pubescent branches, brown when young: lvs. obovate, abruptly cuspidate, cuneate at the base: cymes sessile, terminal, 3–7-fl'd.: sepals linear from an elliptic base, acute; corolla-tube pale yellow, the lobes deep yellow, ovate, 6–8 in. long, including the tails: follicles slender, brown, mottled with yellow, coriaceous. Trop. Afr. Ct. 36:1241.—*S. Prüssii*, Engl. & Pax. Rambling or climbing shrub, up to 12 ft. high: branches glabrous, brown or red-brown: lvs. elliptic or oblong to obovate or ovate, abruptly acuminate, $2-5 \times 1\frac{1}{2}$ –2 in.: cymes terminal, corymbose, many-fl'd.: sepals linear-oblong or linear; corolla cream-colored to orange with purple spots and streaks in the throat and purple tails, the lobes ovate, suddenly constricted and produced into tails 1 ft. long. Trop. Afr. B.M. 8250.—*S. speciosus*, Reber (*S. capensis*, A. DC.). Glabrous, rambling shrub: branches trailing on other shrubs, sometimes running high up, olive-green: lvs. in whorls of 3–4, rarely the uppermost opposite, oblong-lanceolate to lanceolate, acute, rarely acuminate, $1\frac{1}{4}$ – $3\frac{1}{2} \times \frac{1}{2}$ –1 in., leathery: cymes terminal or pseudo-axillary, corymbiform, few- to 12-fl'd.: sepals lanceolate to linear, sometimes recurved; corolla cream-colored to yellow or orange spotted with red, the lobes attenuate from a somewhat broader base into linear spreading tails about 1– $1\frac{1}{2}$ in. long: follicles very slender, lanceolate, about 6 in. long. S. Afr. B.M. 5713.

F. TRACY HUBBARD.

STROPHOLÍRION (Greek for *twisted rope and lily*, referring to the twining stem). *Liliaceae*. Herbaceous, with a corned base, used for outdoor planting: lvs. few, radical: scape simple, leafless, often twining several feet fls. rose, numerous in a terminal umbel; perianth urn-shaped, 6-lobed; stamens 3; ovary sessile, ovoid, 3-

3740. *Stropholirion californicum*. ($\times \frac{3}{4}$)

celled: caps. included in the persistent calyx, globose.—One species, Calif. Very like *Brodiaea*, and sometimes referred to that genus, but differing in always having 3 stamens and a perianth which is contracted at the throat and saccate at the base. *S. californicum*, Torr. (*Brodiaea volubilis*, Baker). Fig. 3740 (adapted from Pacific R. R. Rep.). In many ways it resembles *Brevortia Ida-Maia*, except that the scape is climbing to a height of 3–4 ft., and bearing an umbel of delicate rosy pink fls. The scape twines readily about any stick or bush that stands near it. Lvs. 1 ft. or more long, keeled, $\frac{1}{2}$ in. or less broad; corm about 1 in. diam. Cent. Calif. B.M. 6123. G.C. III. 20:687. Cult. as for *Brevortia Ida-Maia*. CARL PURDY.

STRUTHIÓPTERIS: *Matteruccia*.

STRÝCHNOS (an old Greek name used by Theophrastus for some plants belonging to Solanaceae). *Loganiaceae*. Scandent shrubs with short tendrils, or trees, of economic importance; some of the species have been introduced into the southern United States.

Leaves opposite, in scandent species some axils bear short clavate tendrils, the adjacent lf. being often suppressed: cymes terminal or lateral; bracts small: fls. white to yellowish; calyx 5–4-lobed; corolla 5–4-cleft, tube short or long or hardly any, lobes valvate; stamens 5; ovary 2-celled (or 1-celled above): berry globose or oblong.—About 220 species, tropics of both hemispheres.

Nux-vómica, Linn. Tree attaining a height of 40 ft.: lvs. ovate, 5-nerved, glabrous, $3\frac{1}{2} \times 2$ in.: cymes terminal, short-peduncled, 1–2 in. diam.; pedicels hardly any: fls. numerous; corolla-lobes glabrous: berry $1\frac{1}{2}$ in. diam., globose, many-seeded. India.—The seeds yield the drugs, nux-vomica and strychnine, and the bark is somewhat used as a tonic.

potatòrum, Linn. f. Tree attaining a height of 40 ft.: lvs. elliptic, $2\frac{1}{2} \times 1$ in., 3-nerved, subsessile, glabrous or nearly so: cymes axillary, nearly sessile, 1 in. diam.: berry $\frac{1}{2}$ – $\frac{3}{4}$ in. diam. India and Ceylon.—The seeds are known as the clearing-nut as they have the property of clearing muddy water when they are rubbed on the inside of the vessel into which it is put.

spinòsa, Lam. Low tree: branchlets slender, armed with pungent spines from the nodes: lvs. obovate or suborbicular, 5-nerved from near the base, glabrous, subcoriaceous: cymes short, dense, terminal, very compound: fls. greenish; calyx-tube very short, segms. linear; corolla-tube short, campanulate, the lobes usually 5, ovate: fr. the size and color of an orange, the shell leathery, the pulp abundant and edible; seeds large. Trop. and S. Afr., Madagascar, and Seychelles.—A promising fr. intro. into the S. U. S.

S. Schumanniana, Gilg (S. Schumann, Hort.). Tree, 12–22 ft. high with axillary recurved spines: lvs. decussate, elliptical, gray-pilose on both surfaces: cymes terminal on the gray branches, many-fl.: calyx gray-hirsute, lobes linear; corolla-lobes deltoid-ovoid: fr. edible. Trop. Afr. Reported as intro. into S. Calif. but not successful.—*S. Völkensis*, Gilg. Tree, 30–40 ft. high: branchlets armed at the nodes with curved pungent spines: lvs. oblong or oblong-ovate, glabrous: cymes lax, many-fl., from the tip of the branches; sepals ovate; corolla-lobes ovate: fr. shaped like an orange, edible. Trop. Afr. Reported as intro. into S. Calif. but not successful.

F. TRACY HUBBARD.

STRYPHODÉNDRON (Greek, *astringent* and *tree*; the bark has a puckery taste). *Leguminosae*. Unarmed trees, usually small, with thick branches, grown in the greenhouse and also outdoors in the extreme S.: lvs. twice pinnate, lfts. small, many-paired, frequently rather broad: fls. small, hermaphrodite or somewhat polygamous, borne in short-peduncled, axillary spikes, 5-merous, sessile; calyx campanulate; petals connate to the middle, finally free; stamens 10, free; ovary short-stipitate, many-ovuled: legume linear, compressed, thick.—Nine species in Trop. Amer.

guianénse, Benth. Branchlets subterete, they and the petioles rusty-tomentellous: pinnæ 6–12 pairs; lfts. with 8–10 pairs of divisions, oblique, oval-oblong, 4–5 lines long, shiny above, reddish beneath: corolla smooth, about 3 times as long as the calyx: pod straight or slightly incurved. Guiana and intro. into Fla.

S. floribundum, Benth. (*Acacia pulcherrima*, Willd.). Spineless: pinnæ 13 pairs; lfts. many pairs, oblong-linear, obtuse, pubescent beneath; petiole pubescent and with 2 convex glands at base: spikes twin, axillary, filiform: fls. 5-parted, pilose. Brazil.

STUÁRTIA: *Stewartia*.

STYLÍDIUM (*stylos*, a column, referring to the body formed by the union of the stamens and style). *Candolleaceae* or *Stylidiaceae*. Herbaceous or somewhat woody perennials of many perplexing species mostly in Australia, seldom grown under glass or in the open in mild climates.

Confusion has arisen in the name of this group, and recent authorities adopt the name *Candollea*, but *Candollea* is itself confused. In 1805, La Billardiére founded the genus *Candollea* for the plants which a few months earlier were named *Stylidium*, Swartz, by Willdenow (Sp. Pl. iv. 146). As the first application of the name *Candollea* was thus invalidated, La Billardiére, in 1806, used *Candollea* for a genus belonging to *Dilleniaceae*; this is the group described on page 653, Vol. II, now included in *Hibbertia* by Gilg in Engler & Prantl's *Pflanzenfamilien*, although kept separate by Benth in *Flora Australiensis* and by Benth & Hooker in *Genera Plantarum*. Although the name *Stylidium*, Swartz, is antedated by *Stylidium*, Loureiro, founded in 1790 on a plant of the *Cornaceae*, Swartz's name stands, since Loureiro's *Stylidium* belongs as a synonym to the earlier genus *Alangium* (see page 243, Vol. I). According to the International Rules, as well as on the principle of fifty years of accepted usage, it is correct to retain *Candollea* for the *Dilleniaceae* plants (page 653) and to use *Stylidium* for the genus we are now considering, as is done by Benth & Hooker. Schönland, however, in Engler & Prantl, and, earlier, F. von Mueller, revive the *Candollea* of 1805 and make *Stylidium* a synonym, and in this case the *Candollea* of 1806 would become *Eeldea* of Durand if it is retained as a genus distinct from *Hibbertia*. According to the *Philadelphica* or American Code, however, the existence of earlier homonyms, no matter whether valid names or synonyms, prevents the use of *Stylidium*, Swartz, and of *Candollea* of 1806, and *Forsteropsis* would apparently be the name to be used for the *Stylidium* of Swartz, while *Eeldea* would replace *Candollea*. The latest monographer, Mildbraed, in Engler's *Pflanzenreich*, hft. 35 (iv. 278. 1908), adopts *Stylidium*, Swartz. It may be said in passing that the generic name *Candollea* has also been used for plants distinct from either of the groups we are here considering, but these applications are of later origin.

The *stylidiids* are of very minor importance horticulturally and scarcely appear in the American trade, although *S. adnatum* has been listed in southern California. The species are difficult of determination in Australia; Mildbraed describes 103. Most of the species "form a rosette or spreading tuft of radical leaves from the midst of which springs the scape. Sometimes the following year the new leaves and scape are close to the old ones, forming a dense, tufted stock, the bases of the leaves sometimes assuming a bulbous appearance; in others, one or two short stems are formed above the old tuft, each crowned by a new rosette and scape, and sometimes several successive tufts of leaves, separated by short stems or branches, may be observed." The plants are more or less lobelia-like, with pink, purplish, yellow, or white fls. in racemes, panicles, or cymes; corolla irregular, five-lobed of which four lobes ascend in pairs and the other (the lip) much smaller and deflexed or sometimes nearly as large as

the others and curved upward; calyx five-lobed, more or less two-lipped; stamens two, united with the style: fruit a capsule, two-valved from the top downward: leaves all radical, or scattered in whorl-like tufts, as described above.

S. adnatum, R. Br. (Candollea adnata, Muell.), has mostly very narrow or linear lvs. scattered along the st., the upper ones crowded in a terminal tuft: fls. pink, nearly sessile in compound racemes or spike-like panicles; sta. 12 in. or less long.—*S. Brunonianum*, Benth. (Candollea Brunoniana, Muell.). Tufted or rarely procumbent, the radical lvs. linear to oblanceolate: scapes 12-18 in. high, with whorls of narrow lvs., and bearing many small pink fls., the corolla-throat appendaged. B.R. 28:15. H.U. 4:72.—*S. ciliatum*, Lindl. (*S. saxifragoides*, Lindl. Candollea ciliata, Muell.)= *S. piliferum*.—*S. dichotomum*, DC. (*S. mucronifolium*, Hook. Candollea dichotoma, Muell.). Low, the scapes 2-4 in. high and glandular-pubescent: lvs. narrowly linear, acute, scattered between tufts at base and top: fls. yellow in a glandular-hairy compound raceme or panicle. B.M. 4538. F.S. 6:606 (as *S. Hookeri*). J.F. 1:59.—*S. graminifolium*, Swartz (*S. Armeria*, Labill. Candollea graminifolia, Muell.). Tufted or somewhat procumbent, the scapes 6-18 in. high: lvs. rather rigid, linear, sometimes denticulate: fls. pink, nearly sessile in a raceme or interrupted spike. B.R. 90. B.M. 1918. J.F. 3:286.—*S. piliferum*, R. Br. Tufted, lvs. linear and hair-pointed, the plant with yellow glandular hairs: scape 6-12 in. high, bearing a raceme or panicle of yellow or whitish or pinkish fls., the corolla-throat not appendaged. B.M. 3883 (as *S. ciliatum*); 4529 (as *S. saxifragoides*). J.F. 1:34.

L. H. B.

STYLÔMA (name refers "to the large indurated styles"). *Palmaceæ*. A genus very recently proposed by O. F. Cook for the Pacific island palms heretofore referred to *Pritchardia* (Journ. Wash. Acad. Sci., 1915, p. 241). *Pritchardia pacifica* under this disposition becomes *Styloma pacifica*, Cook; and the other species on page 2810, Vol. V, become *S. Gaudichaudii*, *S. Martii*, *S. periclarum*, and *S. Thurstonii*, Cook. He keeps *Pritchardia Wrightii* distinct under *Colpotherinx*.

3741. *Stylophorum diphyllum*. (× 1/4)

STYLÔPHORUM (Greek, *style* and *bearing*, in reference to the persistent style). *Papaveraceæ*. Hardy, perennial herbs, with stout rootstocks and yellow sap: lvs. radical, pinnatifid or none; cauline few, lobed or cut: fls. yellow or red; peduncles elongated, solitary or somewhat fascicled; buds nodding; sepals 2; petals 4; stamens many; ovary 2-4-placentae: caps. frequently stipitate, ovoid, oblong or linear, dehiscent from the apex to the base.—Three species, according to Fedde, one from N. Amer., the other two from China.

diphyllum, Nutt. (*Papaver Stylophorum*, Hort.). **CELANDINE POPPY**. Fig. 3741. A hardy perennial

about 1 ft. high, forming large clumps: st. with 2 lvs. at the summit: lvs. light green, pinnately parted: fls. yellow, 2 in. across, in clusters of 3-5. May, June. Moist shade, W. Pa. to Wis. and Ark. B.B. 2:102. J.H. III. 34:475. Gn. 65, p. 283.—An attractive plant of easy cult. in any rich, rather loose, moist soil in either shade or open, but preferably in partial shade. It is easy to transplant.

F. W. BARCLAY.

STYLOPHÝLLUM (Greek, *style* or *column* and *leaves*). *Crassulacæ*. A genus separated from *Cotyledon* and composed mostly of new species: basal lvs. linear, elongated, base sometimes broad clasping: calyx 5-lobed, the lobes ovate, equal and small; corolla campanulate, not angled, white, red, or yellowish, the lobes broad, thin, and spreading, united below into a tube: carpels 5, united below, generally strongly spreading as in *Sedum*.—Twelve species all from Calif. *S. Orcuttii*, Rose. Rather stout and very glaucous, woody at base: lvs. linear: calyx-lobes obtusish; corolla-tube shorter than the calyx, the lobes rather broad and somewhat keeled, rose-colored, not at all tinged with yellow. *S. Calif.* and adjacent islands.—This plant was distributed as *Cotyledon attenuata*, which is probably a different species.

STYRAX (ancient Greek name of *Styrax officinalis*). *Styracaceæ*. **STORAX**. Ornamental woody plants chiefly grown for their handsome flowers.

Deciduous or evergreen trees or shrubs more or less stellate-pubescent: lvs. short-stalked, exstipulate, more or less covered, like the infl., with stellate hairs: fls. white; calyx campanulate, obscurely 5-toothed or truncate; petals 5, connate only at the base; stamens 10, inserted at the base of the corolla and usually somewhat connate below; ovary superior, often united at the base with the calyx, 3-loculed at the base, 1-loculed at the apex; style slender: fr. a drupe, mostly subglobose, fleshy or oftener dry with dehiscent pericarp, 1-2-seeded, with large, subglobose seeds.—About 100 species in the tropical, subtropical, and warmer temperate regions of Amer., Asia, and Eu. There is a monograph by Miss J. Perkins in Engler, Pflanzenreich (IV. 241), *Styracaceæ*, pp. 17-88 (1907). *S. Benzoin* yields the benzoin, a balsamic exudation of the wounded tree; storax, a similar gum-resin, was formerly obtained from *S. officinalis*, but the storax of today is a product of *Liquidambar*.

The storaxes are handsome shrubs of graceful, usually loose and spreading habit with numerous white and mostly fragrant, often pendulous, flowers in racemes or few-flowered clusters, followed by rather insignificant subglobose drupaceous fruits. *S. japonica* and *S. Obassia* are the hardiest and stand the winter in sheltered positions as far north as Massachusetts. *S. americana* is somewhat tenderer; *S. grandifolia* is hardy about Philadelphia and *S. Wilsonii* is probably of the same hardiness; *S. officinalis* is hardy only South. They are well adapted for borders of shrubberies or as single specimens on the lawn, and thrive best in a light, porous soil. Propagation is by seeds which are usually profusely produced in cultivation, sown soon after ripening, and by layers sometimes grafted on *Halesia carolina*; *S. japonica* and *S. americana* may also be grown from cuttings, but usually only a small percentage will root.

A. Fls. in many-fl'd. racemes: lvs. 2-10 in. long.

B. Young branchlets, petioles, and racemes grayish-tomentose.

grandifolia, Ait. Shrub, 4-12 ft. high: lvs. oval to obovate, shortly acuminate, usually narrowed toward the base, denticulate or almost entire, glabrous above, grayish-tomentose or -pubescent beneath, 2½-6 in. long: fls. fragrant, in loose racemes 3-6 in. long or sometimes in clusters; corolla fully ½ in. long, with spreading, oblong petals: fr. subglobose, about ½ in. across.

May. S. Va. to Fla. L.B.C. 11:1016 (poor). B.B. (ed. 2) 2:723.

BB. *Young branchlets, petioles, and racemes soon glabrous.*

Obassia, Sieb. & Zucc. Shrub or small tree, 30 ft. high: young branchlets and petioles covered with a quickly disappearing floccose rusty tomentum: lvs. orbicular to broadly obovate or oval, abruptly acuminate, usually rounded at the base, remotely dentate above the middle and sometimes tricuspidate at the apex, glabrous above, pubescent beneath, 6–10 in. long: fls. fragrant, in racemes 5–7 in. long; rachis glabrous; pedicels and calyx finely tomentose; corolla $\frac{3}{4}$ in. long, with slightly spreading obovate-oblong petals: fr. $\frac{3}{4}$ in. long, ovoid, pointed. May. Japan. S.Z. 1:46. B.M. 7039. G.C. III. 4:131 (not correct in regard to habit). A.F. 12:30. M.D.G. 1898:16. S.I.F. 1:80. G. 36:531.

AA. *Fls. in few-fld. clusters or short racemes: lvs. $\frac{1}{2}$ –3 in. long.*

B. *Lvs. $\frac{1}{2}$ –1 in. long, serrate or denticulate, tomentose beneath.*

Wilsonii, Rehd. Small compact shrub, to 6 ft.: lvs. rhombic-ovate or oval, obtuse or acutish, sparingly toothed or denticulate, sparingly pubescent above, white-tomentose beneath, $\frac{1}{2}$ –1 in. long: fls. short-stalked in 3–5-fld. clusters, $\frac{1}{3}$ – $\frac{1}{2}$ in. long; calyx stellate-pubescent; corolla-lobes oblong: fr. globose-ovoid, $\frac{1}{4}$ in. long, finely velvety. May, June. W. China. B.M. 8444. G.M. 56:369. G. 36:161. R.H. 1914, p. 33.—Handsome little shrub, begins to bloom when about two years old and less than a foot high.

BB. *Lvs. 1–3 in. long.*

C. *Petals 5–8: lvs. pubescent beneath, entire, usually obtuse.*

officinalis, Linn. Shrub or small tree, to 20 ft.: lvs. broadly oval or ovate, obtuse or acutish, entire, stellate-pubescent, at least when young, 1–2 $\frac{1}{2}$ in. long: fls. in few-fld. tomentose clusters; pedicels about as long as calyx; corolla $\frac{3}{4}$ in. long, with 5–7 oblanceolate petals; stamens 10–16, with the filaments pubescent and connate at the base. April–June. Eu., Asia Minor. L.B.C. 10:928. Var. **californica**, Rehd. (*S. californica*, Torr.). Shrub, 5–8 ft.: corolla usually 1 in. long, sometimes with 8 petals; stamens connate nearly one-third. Calif.

cc. *Petals 5: lvs. almost glabrous, acute.*

d. *Pedicels about as long as calyx, puberulous.*

americana, Lam. (*S. glabrum*, Cav. *S. laevigatum*, Ait.). Shrub, 4–8 ft. high: lvs. oval to oblong, acute at both ends or acuminate, entire or serrulate, bright green and almost glabrous, 1–3 in. long: fls. nodding, in few-fld. clusters; pedicels about as long as calyx or little longer, puberulous; corolla about $\frac{1}{2}$ in. long, almost glabrous, with spreading or reflexed, lanceolate-oblong petals; calyx-teeth minute, acute. April–June. Va. to Fla., west to Ark. and La. B.M. 921. L.B.C. 10:960. B.R. 952 (as *Halesia parviflora*). Var. **pulverulenta**, Perkins (*S. pulverulenta*, Michx.). Lvs. stellate-pubescent, at least when young: fls. on tomentose pedicels. S. Va. to Fla. and Texas. B.B. (ed. 2) 2:723.

dd. *Pedicels $\frac{3}{4}$ –1 in. long, glabrous.*

japonica, Sieb. & Zucc. Fig. 3742. Shrub or small tree, becoming 30 ft. high, with slender spreading branches: young branchlets and lvs. with stellate pubescence, which soon disappears: lvs. broadly elliptic to elliptic-lanceolate, acute at both ends, often acuminate, cre-

nately serrulate, glabrous, 1–3 in. long: fls. pendulous, in 3–6-fld. glabrous racemes; corolla about $\frac{1}{2}$ in. long, with slightly spreading, elliptic, tomentulose petals; calyx usually with short and broad, obtuse teeth. June, July. Japan, China. S.Z. 1:23. Gt. 17:583. B.M. 5950 (as *S. serrulatum*). M.D.G. 1899:229, 230. R.H. 1888, p. 320. S.I.F. 1:80. G.W. 3, p. 207. Gn. 76, p. 588. Gn.W. 12:705. G. 32:485; 36:533. G.M. 48:347; 53:143.—The hardest species and exceedingly handsome in bloom with its profusion of gracefully drooping white fls.

S. Benzoin, Dry. Small tree, allied to *S. japonica*: lvs. stellate-tomentose beneath, also pedicels and calyx. Malay Archipelago.—*S. dasyantha*, Perkins. Shrub or small tree, to 25 ft.: lvs. obovate to oblong, acuminate, serrulate, sparingly stellate-pilose, 2 $\frac{1}{2}$ –4 in. long: fls. nearly $\frac{1}{2}$ in. long, in many-fld. racemes or panicles. Cent. China. Var. *cinerascens*, Rehd. Lvs. stellate-tomentose beneath.—*S. Hemslayana*, Diels. Shrub or tree, to 30 ft.: lvs. broadly ovate, acuminate, serrate, pubescent on the veins beneath, 3–6 in. long: fls. $\frac{3}{4}$ –1 in., in long racemes, sometimes panicked. Cent. and W. China. Gn. 79, p. 205. B.M. 8339.—*S. platanifolia*, Engelm. Allied to *S. californica*. Almost glabrous: lvs. undulate or irregu-

3742. *Styra japonica*. (× $\frac{1}{4}$)

larly sinuately lobed. Texas.—*S. serrulata*, Roxbg. Shrub or tree, 40 ft. high, allied to *S. americana*: lvs. usually elliptic-oblong, acuminate, distinctly serrulate: fls. short-pedicelled, in 5–10-fld. short racemes; calyx and pedicels tomentose. E. India.—*S. Shiraidana*, Makino. Small tree: lvs. rhombic to orbicular, coarsely toothed, nearly glabrous, 1 $\frac{1}{2}$ –3 in. long: fls. nearly 1 in. long, in short racemes. Japan.—*S. Veitchiorum*, Hemsl. & Wilson. Tree, to 30 ft.: lvs. lance-ovate to oblong-ovate, acuminate, denticulate, glabrous, 3–4 $\frac{1}{2}$ in. long: fls. over $\frac{1}{2}$ in. long, in many-fld. racemes or panicles: bears the large galls found on *S. Benzoin* and other species. Cent. China.

ALFRED REHDER.

SUCCISA (succise, præmorse; cut off at the lower end, referring to the root). *Dipsacæ*. Three or 4 herbs, by some authorities incl. in Scabiosa, of the Medit. region to Trop. Afr., marked by the soft or herbaceous scales or palea (involucels) subtending the florets in the head, and by other technical characters. To this genus or group belongs the "teufelsabbiss" of the Germans. The plants are little known in cult., but *S. australis*, Mert., is listed abroad among outdoor perennials. Nearly or quite glabrous: lvs. ovate-elongate and acuminate, entire, the lower ones somewhat auriculate: heads ovate, with lilac-violet or ochroleucous fls.; scales of involucre in 2 series. *S. pratensis*, Moench. (*Scabiosa Succisa*, Linn.), may be cult.: root præmorse (as if cut off): radical lvs. ovate-lanceolate, acuminate and entire, the cauline ones connate: scales of involucre in 2 or 3 series.

SUCCULENTS: *Planting*, page 2672.

SUGAR-APPLE: *Annona squamosa*. S.-Cane: *Saccharum*.

SUKSDÓRFIA (W. N. Suksdorf, botanist of Washington state). *Saxifragaceae*. One species as recently delimited, a slender perennial, *S. violácea*, Gray, growing on wet cliffs and rocks, Mont. to Ore. and Wash.: glandular-pubescent, the rootstock bearing bulblets: fls. small, pink, in few-fl'd. panicles on leafy axial shoots: st. 1 ft. or less high: lvs. reniform, 5-7-round-lobed, the lower ones petioled and the upper ones on the st. sessile: sepals, petals, and stamens 5, the anthers almost sessile.

SULLIVÁNTIA (William S. Sullivan, American bryologist). *Saxifragaceae*. Slender perennial herbs, useful in wild-gardens and for colonizing, but scarcely in cult. Four species are now recognized, all natives in the U. S., mostly local, allied to *Saxifraga*: rootstock horizontal, short: fls. perfect, white or whitish, regular, small, in a panicle on a nearly leafless scape-like st.: lvs. mostly basal, reniform to orbicular, shallowly lobed and coarsely toothed, long-petioled: sepals 5; petals 5, clawed; stamens 5, the filaments subulate, shorter than the petals; carpels united below the beaks, forming erect follicles, the seeds winged. *S. Sullivanii*, Brit. (*Saxifraga*?) *Sullivanii*, Torr. & Gray. *Sullivania ohionis*, Torr. & Gray). Fl.-st. 6-16 in. high, growing on limestone cliffs in Ohio and Ind. *S. Hopemanii*, Coul., differing in 3-nerved rather than 1-nerved sepals and much smaller stature, grows from Wis. and Minn. to Colo.

SUMACH: *Rhus*.

SUNDEW: *Drosera*. S.-drop: *Primula*; also *Oenothera fruticosa* and allies. S. Rose: *Helianthemum*.

SUNFLOWER: *Helianthus*. Since the publication of Volume III some progress has been made in the study and analysis of sunflowers, and a brief account of the principal results follows: The investigations of A. H. Church, of Oxford, have shown that the typical unbranched monocephalous sunflower (*Helianthus annuus*, Linn.), which is not known in the wild state, has come down to us unchanged from ancient times, and existed in cultivation in pre-Columbian America. It was grown at Madrid and described by Dodonæus as early as 1567. (American Naturalist, XLIX (1915), page 609). It is found that "marking factors" exist in rays of annual sunflowers, which give rise to different patterns when the anthocyan colors are introduced. The system of markings in *H. annuus* and varieties is quite different from that in *H. cucumerifolius* (or *H. debilis* var.) and varieties; thus the red varieties of *H. cucumerifolius* produced by Herb, of Naples, have rays reddened at the end, or have a red stripe down the middle of the ray, or may have the whole upper surface of ray deep brownish pink, and the under side entirely clear light sulfur-yellow. (Journal of Heredity, VI (1915), page 542). In a culture of red sunflowers (*H. annuus*, variety) at Boulder, Colorado, a collarette form has been obtained in some numbers, both in the chestnut and wine-red colors. The ray-florets have extra lobes, which are small and directed inward, the structure being like that of the collarette dahlia, though less regular. The type will doubtless be improved in course of time. (Gardeners' Chronicle, November 6, 1915, page 295.) Varieties are now obtained, but have not yet been sufficiently selected and isolated, with two or more rows of rays, in the manner of the star dahlias. It is hoped that some very good forms of the red sunflower will be developed along these lines. A new form of the wine-red sunflower has the bicolor pattern, with the background pale (dilute) orange instead of primrose. This gives, in certain cases, an exceedingly rich and bright color. By crossing the silky-haired *H. argophyllus* with vinous *H. annuus*, and again crossing the resulting plants with vinous *H. annuus*, a very pretty

new hybrid has been obtained, the rays very pale yellow, tinted with vinous or with a broad ring of color at the base. It has the *H. argophyllus* foliage.

As early as 1896 (Bulletin Torrey Botanical Club, vol. 23, page 357) hybrids between annual and perennial sunflowers were recorded, but without details. The hybrid *H. annuus* × *H. scaberrimus* (*rigidus*) was listed by Thellung in 1913. In 1913 Leonard Sutton in England used the pollen of *H. rigidus* (*H. scaberrimus*) on the red variety of *H. annuus*, and obtained fertile seed. The F₁ had the characters of the perennial parent, but Sutton reports that an F₂ plant has been obtained with small streaks and splashes of red. In 1914 Mrs. Cockerell used the pollen of the perennial *H. pumilus* on vinous *H. annuus*, and obtained seeds which produced plants in 1915. These resembled the perennial parent, and formed rosettes only during the first season. An attempt to force these into flower in the greenhouse in the winter of 1915-1916 totally failed; but three seeds of the original lot placed in a coldframe early in 1916 produced plants, one of which is a rosette, while the other two have formed no rosette, and have flowered the first season, like an annual. The largest of the first lot of plants from the *H. pumilus* × *H. annuus* cross flowered about the middle of July, 1916, and in its mature form showed a curious combination of characters. The rays, however, were entirely without red, and as is usual with perennials, gave a red color with caustic potash. (Since this was written, one of the hybrids has flowered showing the collarette character, and the lobes forming the collarette are largely red.) This hybrid plant has a curiously close resemblance to the horticultural form known as Daniel Dewar. The broad leaves with well-developed petioles are, however, like those of *H. pumilus* and *H. annuus*, not Daniel Dewar. The strongly serrate margins resemble *H. annuus*. At the present time the hybrids between annual and perennial sunflowers present many problems, and are exceedingly puzzling. It seems probable that results of considerable botanical and horticultural interest will eventually be obtained.

S. Alexander of Michigan has made an elaborate study of the forms of perennial sunflowers growing in his region. He finds that only part of the species are perennial in the strictest sense, the others reproducing by underground branches, having no permanent budding crowns. He also finds that the forms are extremely diverse and has recognized over 600 minor species, differing in a variety of characters. This great diversity of character should afford the basis for many interesting horticultural forms. The nature of these lesser types, from the standpoint of genetics, has not been ascertained. If crossing has taken place, the various combinations arising may have been perpetuated and increased by the system of vegetative reproduction by "earth-branches," which would give us areas covered with plants of the same composition, constituting apparently fixed and constant "species." Alexander finds, however, that the true stationary perennials present a great diversity of forms, though they appear to be far less numerous than are the migrators. T. D. A. COCKERELL.

SURINAM CHERRY (Fig. 3743), *Eugenia uniflora* (E. *Michellii*) of the family Myrtaceae, is a large shrub, sometimes becoming a small tree, but commonly branching close to the ground and forming a broad compact bush 6 to 12 feet high. It is indigenous to Brazil, where it is called pitanga. In Cuba it is cultivated under the name of cerezo de Cayena, or Cayenne cherry; in Florida it is a common garden plant, and is hardy as far north as Putnam County, according to Reasoner. In recent years the fruit has begun to appear in the markets. In California the plant does not seem to fruit very freely, and has never become generally cultivated, though it is sufficiently hardy to be grown in the open ground throughout the southern part of the state.

The branchlets are rather thin and wiry: the leaves

subsessile, opposite, entire, ovate, subacuminate at the apex and rounded to subcordate at the base, 1 to 2 inches long, glabrous, reddish when young but when mature of a deep glossy green color. When crushed they emit a pungent odor which is rather agreeable; in Brazil they are often gathered and scattered over the floors of the houses, the odor which they give off when trampled upon being appreciated and considered efficacious in driving away flies. The white slightly fragrant flowers are about $\frac{1}{2}$ inch in diameter, solitary in the axils of the leaves on slender peduncles up to 1 inch long; the sepals are four, oblong, concave, ciliate; the petals four, oblong-obovate, cupped, ciliate. The stamens are numerous, erect in a large cluster, the filaments filiform and the anthers oval, laterally dehiscent. The style is slightly longer than the stamens, filiform, the stigma simple; ovary bilocular. See page 1162.

The fruits are produced in great abundance during the early spring in south Florida, with frequently a second crop later in the summer; they are subglobose, about 1

3743. Surinam cherry.
($\times \frac{3}{4}$)

inch in diameter or somewhat less, prominently eight-ribbed longitudinally, deep crimson in color when fully ripe, each containing one large spherical seed or two hemispherical ones. The flesh is soft and melting, very juicy, of the same color as the thin skin and of an aromatic, subacid flavor. The fruit is a great favorite in parts of Brazil, where it is commonly eaten out of hand or made into jellies, preserves, and sherbets.

The plant is of very simple culture. It is usually propagated by seeds, which will germinate upon the ground beneath the bush if the fruits are allowed to fall. They can be sown in flats of light sandy loam, and covered to the depth of about an inch. Germination usually takes place within a few weeks. When a foot high, the plants may be set out in the open ground, where they require very little attention. They succeed remarkably well on the shallow sandy soils of southeast

Florida, but in their native home are found upon clay or clay loam. Their behavior in California indicates that they are reasonably drought-resistant. Because of their attractive appearance and close, compact growth they are often used in Brazil for hedges, for which purpose they are excellent.

F. W. POPEOE.

SUTHERLÁNDIA (named for James Sutherland). *Legumindœ*. Tender canescent shrubs, hardy in the extreme S., otherwise grown in the greenhouse: lvs. unevenly pinnate; lfts. many, very entire, without stipels; stipules small, narrow; fls. showy, scarlet, few in short axillary racemes; calyx-teeth subequal; standard erect, spreading at the top; wings small, oblong; keel erect, incurved, rather acute, exceeding the standard; stamens 1, free from the standard, the others connate in a sheath; ovary stipitate: legume ovoid, membranaceous, much inflated, rather indehiscent.—One species, *S. Afr.* Prop. by seeds and said to be easily raised from cuttings. The seeds are generally sown in June or July and the plants wintered in the greenhouse, where they should have very moderate watering and as much air and light as possible. Grown for the bloom.

frutescens, R. Br. Shrub, about 3 ft. high: lvs. with 9-11 pairs of lfts. and an odd one: fls. drooping and in the best variety 1 in. or more long, not pea-shaped: pod sometimes $2\frac{1}{4} \times 1\frac{1}{4}$ in., bladder-like. *S. Afr.* G.W. 14, p. 383. Var. *communis*, Harv., has lfts. glabrous above, elliptical or oblong: ovaries and pods glabrous. B.M. 181 (as *Colutea frutescens*). R.H. 1896, p. 206. Var. *tomentosa*, Harv. Lfts. shorter and broader, obovate or obovate, silvery white on both sides: ovaries and pods hispid. Var. *grandiflora*, Hort. (*S. floribunda*, Carr., not Vilm.), has large red fls. and does not bloom until the second year. R.H. 1871:610. Var. *alba*, Hort. (*S. floribunda*, Vilm., not Carr.), has white fls.

F. TRACY HUBBARD.†

SWAINSONA (named for Isaac Swainson, an English horticulturist of the latter part of the eighteenth century). Often incorrectly spelled *Swainsonia*. *Legumindœ*. Glabrous or subappressed-pilose herbs or subshrubs, adapted to greenhouse culture or out-of-doors in the extreme South.

Leaves odd-pinnate; lfts. many without stipels; stipules frequently herbaceous, base broad, rarely bristle-like; fls. blue-violet, purple, red, rarely white or yellowish, in axillary, usually peduncled racemes; calyx-teeth subequal or the 2 upper shorter; standard orbicular or reniform, spreading or reflexed; wings oblong, falcate or somewhat twisted; keel broad, incurved, obtuse; stamens 9 and 1; ovary sessile or stipitate, many-ovuled: legume ovoid or oblong, turgid or inflated, coriaceous or membranaceous.—About 30 species, Austral. Differs from *Colutea* chiefly in smaller stature and the large lateral stigma. By far the most popular kind is *S. galegifolia* var. *albiflora*.

A. *Standard with prominent oblique or longitudinal calli: pod stipitate, thin, inflated.* (*S. Maccullochiana* probably has no calli; cf. under AA.)

B. *Calyx densely white-tomentose.*

Greyana, Lindl. (*S. grandiflora*, R. Br.). Perennial or subshrub, 2-3 ft. high: sts. erect or ascending, young shoots and lvs. white-tomentose, becoming glabrous: lfts. 11-21, oblong, obtuse or retuse, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. large, pink, in long, erect, pedunculate racemes; calyx dense white-tomentose, teeth short; standard $\frac{3}{4}$ in. diam., with 2 prominent, erect, plate-like calli, wings shorter, keel incurved, obtuse: pod stipitate, inflated up to 1 $\frac{1}{2}$ -2 in. long. Austral. B.M. 4416. B.R. 32:66. H.F. 3:72.

BB. *Calyx glabrous or nearly so.*

galegifolia, R. Br. (*Vicia galegifolia*, Andr. *Colutea galegifolia*, Sims. *S. Osbornii*, Moore). Small gla-

brous attractive shrub, with long flexuose or half-climbing branches: lfts. 5-10 pairs and an odd terminal one, small, oblong and obtuse or somewhat emarginate: racemes axillary and mostly exceeding the foliage, bearing rather large deep red fls.: pod 1-2 in. long, much inflated, stipitate. Austral. B.M. 792. H.F. II. 4:276. J.F. 3:304. J.H. III. 49:547.—An old-time garden plant, blooming freely in a cool- or intermediate house along with carnations and roses. It thrives well either as a pot-plant or in beds. It is hardy at San Francisco. It is a nearly continuous bloomer. Cuttings taken in late winter bloom in summer; these plants may then be transferred to the house for winter bloom, although maiden plants are to be preferred. By cutting back old plants, new bloom may be secured. Cuttings grow readily. The plant is easy to manage. The original form of swainsona is little known in cult., but the advent of the white form has brought the species to the fore.

Var. *albiflora*, Lindl. (var. *alba*, Hort. *S. albiflora*, Don). Fig. 3744. Fls. pure white. B.R. 994. L.B.C. 17:1642. A.F. 8:1173; 10:611; 11:1180. Gng. 5:185.—In N. America this is one of the most popular of florists' white fls. for use in winter decorations. It has been called the "winter sweet pea" because of the shape of the fls., but it has no fragrance. The delicate bright green foliage affords an excellent contrast with the pure white fls. This variety is often grown at the end of a rose- or carnation-house, or trained on a trellis. It likes abundant sunlight, rich soil, and liquid manure. When allowed too much root-room, the plants become very large and are slow to bloom, wherefore a large pot or tub is preferable to the border.

Var. *violacea*, Hort., has rose-violet fls., and is somewhat dwarf. *S. coronillæfolia*, Salisb., probably represents this form or something very like it. B.M. 1725. *S. coronillæfolia* is an older name than *S. galegifolia*, and if the two names are considered to represent the same species the former should be used.

Var. *rosea*, Hort., has pink fls.

AA. *Standard without callosities: pod various.* (*S. Maccullochiana* may have calli.)

B. *Lfts. glabrous above, puberulent beneath.*

Maccullochiana, F. Muell. Shrub, erect, up to 8 ft. high, pubescent: lvs. pinnately compound, 8-10 pairs of lfts., which are elliptic or obovate, mucronate, rather glabrous above, puberulent beneath; stipules obliquely deltoid: raceme many-flid.: fls. reddish purple; standard ovate-obicular: wings oblong, rounded, base auriculate; keel slightly curved, obtuse: pod 2 in. long, stipitate. N. W. Austral. B.M. 7995.

BB. *Lfts. more or less pubescent on both surfaces.*

c. *Fls. violet-purple: lfts. 9-15 pairs.*

lessertiiæfolia, DC. (*S. Froëbelii*, Regel). Perennial, 1-1½ ft. high: sts. diffuse or ascending, glabrous except the young shoots and foliage which are more or less gray-appressed-pubescent: lfts. 9-15 or rarely more, oblong, obtuse, mucronate or almost acute, ½-¾ in. long; stipules rather broad: fls. rather small, violet-purple, in short racemes, sometimes reduced to umbels or heads; calyx more or less pubescent with black appressed hairs; standard nearly ½ in. broad without callosities, wings shorter, keel very obtuse, almost hood-shaped: pod sessile, inflated, ¾-1 in. long. Austral. Gt. 3:89.

cc. *Fls. lilac-rose: lfts. 6-10 pairs.*

ecallösa, Sprague. Herb, erect, about 2 ft. high, pubescent: lvs. 3-5 in. long; lfts. 6-10 pairs, elliptic-oblong, obtuse or retuse, sometimes mucronate, ½-¾ in. long, pubescent on both surfaces; stipules deltoid at base, apex subulate: racemes axillary, 4-5-flid.: fls. lilac-

rose; standard without calli, 7-8 lines diam., much longer than the wings; keel broad, obtuse; ovary silky. W. Austral.

S. alba, Hort., is mentioned in the horticultural journals as a form with snow-white fls.; possibly only a variation of *S. galegifolia*. G.W. 3, pp. 353, 354; 11, p. 13. Var. *grandiflora*, Hort., is offered in the trade.—*S. atrococcinea*, Carr. Similar to *S. Ferrandii* but with larger lvs.: infl. large; peduncle slightly purplish: fls. purplish red, standard broad-spread, 2-lobed, slightly convex, with a white spot at base, keel brilliant red-violet. A horticultural form.—*S. Ferrandii*, Hort. Perennial, 12-20 in. high, much branched: lvs. compound, unevenly so; lfts. numerous, elliptic, apex rounded, glabrous: fls. in axillary racemes; peduncle short and arched; stand-

3744. *Swainsona galegifolia* var. *albiflora*. (X¼)

ard and broadly expanded; wings much reduced; keel small. Probably of garden origin. Var. *alba*, Hort., has pure white fls. Var. *carminea*, Hort., has carmine-pink fls.—*S. grandiflora* var. *alba*, Hort., is offered in the trade, very probably is a form of *S. galegifolia*.—*S. rosea* var. *grandiflora*, Hort., is offered in the trade.—*S. splendens*, Hort., appears in the trade.

F. TRACY HUBBARD.†

SWEET ALYSSUM: *Alyssum maritimum*. S. Bay of general literature is *Laurus nobilis*; in America, *Magnolia glauca*. S.-brier: *Rosa rubiginosa*.

SWEET CICELY, or SWEET-SCENTED CHERVIL (*Myrrhis odorata*, Scop., which see), indigenous to Europe on the banks of streams, is a graceful hardy perennial 3 feet tall, with very large downy grayish green, much-divided leaves, hairy stems and leaf-stalks, small, fragrant white flowers, and large brown seeds of transient vitality. The leaves, which have an aromatic, anise-like, sweetish flavor and odor, characteristic of the whole plant, are still occasionally employed in flavoring soups and salads, though their use as a culinary adjunct, even in Europe, is steadily declining. In American cookery, the plant is almost confined to the unassimilated distinctly foreign population. Though easily propagated by division, best results are obtained from seed sown in the autumn either spontaneously or artificially; the seedlings, which appear in the following spring, are set 2 feet apart each way in

almost any ordinary garden soil. Spring-sown seed frequently fails to germinate. When once established common care will be sufficient.

SWEET CLOVER: *Melilotus alba*. **S. Fern:** *Comptonia*. **S. Flag:** *Acorus Calamus*. **S. Gale:** *Myrica Gale*. **S. Gum:** *Liquidambar*.

SWEET HERBS. The term "sweet herbs" has long been applied to the fragrant and aromatic plants used in cookery to add zest to various culinary preparations, principal among which are dressings, soups, stews, and salads. At the commencement of the nineteenth century many were to be found in gardens and kitchens that now have been dropped entirely or have but very limited use. Perhaps no group of garden plants during this time has been marked by so little improvement. Except in parsley, very few distinctly new or valuable varieties have been produced or disseminated. This is mainly due to the prevailing ignorance of their good qualities, to which ignorance may be charged the improper handling, not only by the grower, but by the seller and often by the final purchaser. With the public duly awakened to the uses of herbs, improvements in growing, handling, and in the plants themselves will naturally follow, to the pleasure and profit of all.

In this country the herbs best known and appreciated are parsley, sage, thyme, savory, marjoram, spearmint, dill, fennel, tarragon, balm, and basil, arranged approximately in their order of importance. Since parsley is more extensively used as a garnish than any other garden plant, it is grown upon a larger scale than all other herbs combined. Hence some seedsmen do not rank parsley with sweet herbs. Sage is the universal flavoring for sausage and the seasoning *par excellence* for rich meats such as pork, goose, and duck. It is more widely cultivated than thyme, savory, and marjoram, which have more delicate flavors and are more popular for seasoning mild meats, such as turkey, chicken, and veal. With the exception of spearmint, without which spring lamb is deemed insipid and the famous mint julep a thing of little worth, the remaining herbs mentioned above are scarcely seen outside the large city markets, and even there they have only a very limited sale, being restricted mainly to the foreign population and to such restaurants and hotels as have an epicurean patronage.

In many market-gardens especially near to the large cities, sweet herbs form no small source of profit, since most of them, when properly packed, can be shipped in the green state even a considerable distance, and when the market is over-supplied they can be dried by the grower and sold during the winter. Probably more than one-half the quantities used throughout the country are disposed of in the latter manner.

As a rule, the herbs are grown as annuals and are propagated from seed sown in early spring, though cuttage, layerage, and division of the perennials are in favor for home practice and to a certain extent also in the market-garden. Commercially they are most commonly grown as secondary crops to follow early cabbage, peas, beets, and the like. In the home-garden they are frequently confined to a corner easily accessible to the kitchen, where they remain from year to year. In general, herbs should be planted on good light garden soil of fine texture, kept clean by frequent cultivation, gathered on a dry day after the dew is off, dried in a current of warm, not hot air, rubbed fine and stored in air-tight vessels.

For specific information, see articles on the following: *Anise, Angelica, Balm, Basil, Caraway, Coriander, Dill, Fennel, Hyssopus, Mentha, Origanum* (Marjoram), *Parsley, Sage, Samphire, Savory, Tarragon*. Also book on "Culinary Herbs," M. G. Kains.

M. G. KAINS.

SWEET MARJORAM: *Origanum*.

SWEET PEA. The popular name of *Lathyrus odoratus*, one of the Leguminosae, grown for its handsome and fragrant flowers. See *Lathyrus* for botanical account; for structure of the flower, see *Legume*; see also *Orobus*.

Because of its range of color, beauty of form, fragrance, and value as cut-flowers, the sweet pea is not only the queen of the large genus to which it belongs, but now ranks first among annual flowers. It has been long cultivated in gardens, and in recent years in America it has risen to a place among the five leading commercial cut-flowers.

The sweet pea is a native of the island of Sicily and was first described by Father Franciscus Cupani, a devout Italian monk and an enthusiastic botanist, in a small work published at Panormi in 1695. Cupani sent seeds in 1699 to Dr. Uvedale at Enfield, England, and to Caspar Commelin at Amsterdam, Holland. The latter published a figure and description of the plant in his "Horti-Medici Amstelodamensis" (1697-1701). From this description it is learned that the flowers had purple standards and sky-blue wings, were fragrant, and that the plants were climbing in habit, as they grew to a height of 6 or 7 feet. A white-flowered variety of the sweet pea appears to have been known in 1718, and in 1737 Burmann called attention to the pink-and-white-flowered form. Although he admitted that his plant differed only in the color of the flowers from that described by Cupani, and which, he says, occurred frequently in gardens, Burmann proceeded to make a new species, *Lathyrus zeylanicus*, because he received the seeds among a collection of plants from Ceylon. Later botanists have not found the sweet pea growing wild in Ceylon, from which the authorities conclude that a mistake was made. This form was named Painted Lady and was grown until about 1900, when it gave way to its improved form, Blanche Ferry.

Sweet pea seeds were offered for sale as early as 1724. The three colors mentioned appear to have been the only cultivated varieties until 1793, when the black and scarlet varieties were catalogued. In 1837 the first striped variety, in 1860 a yellow-flowered and also the Blue Edged varieties, were offered. The latter was white with a distinct blue edge. Later this form was known as Butterfly, and it was the forerunner of the Picotee section. In 1865 Invincible Scarlet won the first certificate awarded a new sweet pea. Crown Princess of Prussia, the first of light pink varieties, was offered in Germany in 1868. Adonis (1882) was the first of the rose-pink varieties. Until 1880 (a period of 185 years) little improvement had been made in the sweet pea, and it had not been given the attention that had been bestowed upon the dahlia, verbena, hollyhock, or the rose. There were nine distinct varieties in 1860, and although many new names appeared during the next twenty years, these mainly represented supposed improved strains of the existing colors. It is very probable that not more than fifteen distinct varieties of sweet peas existed when Henry Eckford, the great specialist, began his remarkable work.

No one can understand the improvement in sweet peas within the last forty years unless one considers the form of the flowers as well as the limited number of colors which then existed. The oldest illustrations of the sweet pea show the wings to be more prominent than the standard, and although there appears to have been some improvement in the size of the standard before 1875, nevertheless the flower was lacking in many respects. The standards of most of the varieties had a tendency to reflex at the edges, and the apical notch was very prominent. Often there were side notches which caused the standard to droop forward. The natural line of improvement, aside from securing better colors or color combinations, was to round out the outline of the standard and to give it a more expanded form and greater substance.

CIX. Sweet peas of the Spencer or Waved type.

Eckford, after long experience and signal success as a breeder of florists' flowers, began his work on the sweet pea about 1876. Beginning with a few varieties, he patiently crossed and selected for several years before he began to secure results. His first notable variety, Bronze Prince, was awarded a first-class certificate by the Royal Horticultural Society in 1882. Soon he began to secure new colors and sent out the deep bronze-blue Indigo King (1885), Orange Prince (1886) and the dark maroon Boreatton (1887). These were followed each year by new colors and improved forms of the flowers. The hooded varieties appeared and gave a new interest to sweet pea improvement. Although many of the hooded varieties that were introduced had flowers in which the standards were hooded so much as to appear triangular in outline, nevertheless many were very beautiful. The perfection of this form was reached in the variety Dorothy Eckford (1903). The increased size of many of Eckford's varieties led to the name Grandiflora sweet peas, but this name is now used to designate all varieties which do not have flowers of the waved or "Spencer" form.

At the time of the great bicentenary conference on the sweet pea held in London in 1900, Eckford had introduced 115 out of the 264 varieties catalogued up to that time. Even in America the Eckford varieties constituted at least 60 per cent of all lists of selected varieties; and in 1916 of the Grandiflora varieties remaining in the trade, as shown by the catalogue of the leading American dealer, more than one-half originated in Eckford's garden at Wem, in Shropshire.

Improvement in America.

The real interest in sweet peas in America began soon after the first introduction of the Eckford varieties by Breck and by Henderson in 1886. Added impetus was given by the introduction of Blanche Ferry in 1889, and by Emily Henderson in 1893. As early as 1890 the sweet pea had become a popular flower in this country, and soon local sweet pea shows were held. The demand for seed greatly increased and the competition in the shows was keen enough to bring about a desire for new and better varieties. The growers looked forward with anticipation for Eckford's annual set of novelties. Meanwhile in England there was not yet the keen interest in sweet pea that had taken hold of America. The popularity of the sweet pea in America was Eckford's constant inspiration to better things, but gradually England came more generally to appreciate this flower with the result that since the waved form appeared the sweet pea has surpassed the popularity it attained in America. The demand for seed was satisfied when it was found that California had superior advantages for seed production. When the Eckford novelties were grown in California they sometimes proved to be unfixed, and some of these variations, together with the results of some artificial crossing, gave the growers some new varieties. Many of the best striped, as well as marbled varieties, are of American introduction.

The most striking novelty in sweet peas, the dwarf or cupid race, was found in California in 1893 and was offered to the seed trade under the name Cupid in 1895. The first variety was white-flowered. This was followed by other varieties, and soon all the colors then known in sweet peas were to be found in the dwarf type. The Cupid sweet pea grows only a few inches high, forming a dense mass. The dwarfing is the result of the extreme reduction in the length of the internodes of stems. The flowers were of the open and hooded form, borne upon short stems, and characterized by little or no fragrance. They appear to thrive under more drought and heat than the ordinary type. They have not succeeded very well outside of California, for in a season of normal rainfall in the East the plants are injured by lying on the moist ground. The appearance of the dwarf sweet pea

offers perhaps the best example of synchronous variation on record. This remarkable variation appeared in California, Germany, England, and France within the period of two years prior to its announcement here by Burpee.

The Cupids were followed by the bush varieties which were considered to be intermediate in growth. This class did not gain much favor and soon disappeared. The snapdragon varieties, which had the standard reduced in size and in contact with the wings, giving the blossom the general effect of a snapdragon, were offered in 1897 but attracted little attention.

The winter-flowering type is the most important of all those originating in America. This type has been perfected in this country and has tremendously enhanced the financial value of the sweet pea as a cut-flower. No other country can begin to approximate the extent of the industry of sweet pea growing under glass.

Development of the waved varieties. (Fig. 3745.)

At the time of the bicentenary of the sweet pea, it seemed as if the future improvement of the sweet pea would be along the line of an increase in the number of flowers to a spike or the securing of new colors or color

combinations in the existing open and hooded forms of the flower. No one seemed to realize that the sweet pea was on the eve of the most remarkable improvement in the form of flower and that along with it would come increased size and a greater average number of flowers to a spike. This was the introduction of the waved or, as it is called in America, the Spencer type, in 1904. The first variety was raised by Silas Cole who named it Countess Spencer in honor of the wife of his employer. The parentage of this variety, although doubted by some, has been given as (Lovely $\times$ Triumph, 1898) $\times$ Prima Donna, 1899.

3745. Waved type of sweet pea. ($\times 1$)

It was shown at various English shows for three years prior to its introduction. Countess Spencer was such an improvement in size, and the form so distinctly new, that it created a sensation. The very large standard and wings were beautifully frilled and waved. The clear pink color was also especially pleasing. This variety was not entirely fixed when it was sent out and soon numerous sports were offered. Among the first of these were the orange-pink Helen Lewis and the carmine-rose John Ingman. Especial difficulty was experienced when the seed of new waved varieties was grown in California, but from this tendency to sport have been secured many of the finest varieties.

About the time that the Countess Spencer appeared, W. J. Unwin found a sport in the variety Prima Donna which he named Gladys Unwin. It was also of the waved type of about the same shade of pink as Countess Spencer, but the flowers were not so large. Soon other

varieties appeared, and for a few years this group vied with the Spencer varieties for popular favor.

The introduction of the waved form aroused great interest and soon large numbers were growing sweet peas for exhibition. Many took up the production of new varieties, and soon new forms were offered in large numbers. In some cases the same sport had been found and given different names. It was seen that hopeless confusion would result if some means were not found to eliminate the synonyms. The English Sweet Pea Society established trial grounds, and when the American Sweet Pea Society was organized in 1909 it established trial grounds in coöperation with the Department of Floriculture of the New York State College of Agriculture at Cornell University, Ithaca, New York. These two national societies hold annual exhibitions, and the American Sweet Pea Society holds exhibitions of winter-flowering varieties at the National Flower Shows held each spring.

Classification.

More than 1,000 varieties of sweet peas have been introduced, but some of these represent strains of existing varieties or were applied to seedlings which did not present any improvement.

3746. Forms of sweet pea flowers: 1, hooded; 2, waved; 3, open. (X1)

The modern sweet pea may be classified as follows: Climbing and dwarf types, the former being subdivided into garden and winter-flowering types. The varieties may be classified as to the form of the flower into open, hooded and waved forms (Fig. 3746).

Garden type	Winter-flowering type	Dwarf type (Cupid)
Open form	Open form	Open form
Hooded form	Hooded form	Hooded form
Waved form	Waved form	

The open form may be further separated into notched and rounded standards; the hooded varieties according to the degree of hooding, the most extreme case being the snapdragon varieties; and the waved varieties may be classified according to the degree of waviness as it appeared to be less or greater than Countess Spencer. This latter classification would require that the flowers be taken from plants under uniform conditions of growth. The National Sweet Pea Society of England classifies sweet peas according to form of the flower into grandiflora or waved, and into thirty-seven color sections as follows: Bicolor; Bicolor (Dark); Light Blue; Dark Blue; Blush-Pink; Lilac-Blush; Carmine; Cerise

(Pale); Cerise (Dark); Cream, Buff, and Ivory; Cream-Pink (Pale); Cream-Pink (Deep); Crimson; Fancy; Lavender; Lavender (Pale); Lilac; Magenta; Marbled and Watered; Maroon; Maroon-Red; Mauve (Pale); Mauve (Dark); Orange-Pink; Orange-Scarlet; Picotee-edged (Cream Ground); Picotee-edged (White Ground); Pink (Pale); Pink (Deep); Rose; Salmon; Salmon (Pink); Scarlet; Striped and Flaked (Purple and Blue); Striped and Flaked (Chocolate on Gray Ground); Striped and Flaked (Red and Rose); White.

The bright sunshine and summer heat of America tends to destroy some of these fine distinctions of color, and the varieties can be grouped in about twenty-five color sections.

Garden culture.

One of the first essentials in sweet pea culture is the choice of an open sunny location, thus providing plenty of light and air. Plants grown in too much shade are weak and spindling in growth, producing few flowers. Any ordinary garden soil is suitable for sweet peas, provided it is sufficiently drained so that in periods of excessive rains the water will not lie on the surface, causing the plants to become yellow and the roots to decay. A heavy soil usually gives better results than a light one as it holds moisture better.

A preparation of the soil as is usually made for the growing of vegetables will give fairly good results; but extra care in the selection and preparation of the soil will be repaid in larger flowers, longer stems, better colors, and a longer blooming-period.

The sweet pea is a deep-rooting plant, and in order to provide suitable conditions so that the effects of drought are overcome, the preparation must be deep and thorough. Deep preparation not only promotes available fertility, but also increases the area in which moisture and nourishment may be found, and the plant responds by sending feeding-roots in all directions.

The preparation of the soil should be made in autumn by trenching at least 2 feet in depth. Since this is an expensive operation, it is advisable instead to dig a trench 16 inches wide and 2 feet deep for each row of peas. If the subsoil is poor or of unsuitable character, it should be removed and replaced with good soil. If the subsoil is very heavy, coarse stable-manure should be mixed with it. A good dusting of air-slaked lime, applied while working the soil in the autumn, is very beneficial. Many soils that have been cultivated for a long time are acid, so that leguminous plants, such as clover or sweet peas, will not grow, or at least do not thrive. Lime corrects this acid condition and, furthermore, it releases plant-food that would not otherwise be available in soils which are not acid. Clay soils are made more open and porous by the use of lime. Half-decayed stable-manure should be mixed with the top soil. Bone-meal applied at the rate of one-quarter to one-half pound to a lineal yard of trench will prove beneficial. The trenches should be filled more than level full, and left rough. During the winter the soil settles, but if in spring the ridges can yet be seen, it will be found that these dry rapidly and thus favor early planting.

Sweet peas for the garden are either sown where the plants are to be grown or are sown in pots and transplanted. Sowing in the open ground may be done either in autumn or spring. South of the latitude of New York, sweet peas may be successfully grown from fall sowings. North of this line the practice is not always successful unless they are planted in a well-drained situation in a sandy loam. The general conditions requisite to success are to plant late so that the seed does not germinate and appear above the surface. If any top growth is made, the plants will be killed in sections where the ground freezes. The rows should be slightly ridged up to prevent water standing over the row. After the ground freezes, a mulch of manure is

applied. Fall-sown sweet peas bloom ten days to two weeks earlier than the spring-sown, and usually produce better flowers.

Sweet peas planted in the spring should be sown early. As soon as the soil is dry enough, the rows should be sown over the trenches prepared in the fall. If the ridges remain, they will dry earlier than level soil. These may be raked level and a drill opened so that the seed may be sown 2 inches deep and 2 inches apart. After the plants have started, but before they begin to stool, they should be thinned so that the plants stand 3 to 4 inches apart. As soon as the tendrils appear, small twigs should be thrust in the ground to support the plants and prevent their injury by the wind.

Sweet peas may be sown in 3- to 4-inch pots (Fig. 3747). A suitable potting-soil made of well-rotted sod, with a little leaf-mold and sand, is best. Four or five seeds are sown in each pot and covered with an inch of clean sand. The sowing should be made six to eight weeks prior to the usual time sweet peas can be sown. The pots are placed in a cool greenhouse or a well-protected coldframe and given plenty of light and air so as to keep the plants short and sturdy. When the plants begin to produce tendrils, insert some small twigs in the pots to support the plants. The plants are gradually "hardened off" so that they may be set out in the open ground. One great advantage of this system is that the grower is independent, to a certain extent, of weather conditions as he can wait until the soil is in the best possible condition before planting. The pots may be set 12 to 18 inches apart, using care to keep the ball of earth intact and without interfering with the supports. Good twiggy brush will make the best supports for sweet peas, but when not obtainable, wire netting makes an excellent support. The latter is durable and looks neater when not covered with vines.

The soil should be frequently stirred, and in hot weather a mulch of straw or lawn-clippings will serve to conserve moisture. If waterings are given in dry weather, they should be copious. The quality of the flowers may be improved by watering with weak manure water, but other liquid fertilizers are seldom used. The prompt removal of all withered flowers and pods is essential in preserving a long period of bloom.

Sweet peas in greenhouses (Figs. 3748, 3749).

The winter-flowering varieties are the most important type yet developed from the garden form, and this type has attained its greatest perfection in the United States. This range of sweet peas is distinct in habit of growth and early-flowering character. Unlike the garden type which apparently ceases growing for a time when the plants are a few inches high while the side shoots develop, the winter-flowering sweet peas grow rapidly until they attain a height of 2 to 4 feet. Then they begin to flower freely, after which time side branches are developed. Winter-flowering varieties planted in September begin to flower between Thanksgiving and Christmas, while varieties of the garden type planted at the same time do not flower until April or May. A knowledge of these characteristics

of the early stage of growth will enable a grower to guard against considerable loss from getting the wrong seed.

Soon after the introduction of *Blanche Ferry*, florists began to grow that variety in boxes placed across the ends of the greenhouse where the plants were near the glass, or small clumps were grown on carnation benches and trained round the purlin posts. With such methods of culture, and with the varieties then available, the flowers were not received on the market in sufficient quantity to be quoted until March or April.

Anton C. Zvolanek, in 1892, found a chance seedling among the variety *Lottie Eckford* which was much earlier and dwarfer in habit. This was later crossed with *Blanche Ferry*, and the result of this line of crossing was the variety *Christmas Pink*, sent out in 1899. Miss Florence E. Denzer, a white variety, was introduced in 1902. Since the latter date many varieties have been sent out. The first varieties had flowers of the open or hooded form, but as soon as the waved sweet peas were introduced, Zvolanek made crosses with the winter-flowering varieties. It was not until 1912 that this class was ready to introduce to the trade, but in 1913 twelve varieties were offered. At present waved varieties of all the colors known among winter-flowering sweet peas are grown, and the older varieties are rapidly disappearing in the competition.

Another group of the early-flowering sweet peas is the *Telemly*, originated in Algeria in 1900. These varieties are an adaptation of the climate of northern Africa where the varieties of the garden type planted in the latter part of September do not flower until May. An exception to this was *Blanche Ferry* which flowered about the first of April. An early sport was found flowering in February, and from this have been developed a number of varieties which flower from Christmas until after the garden varieties come into bloom. Recently waved-flowered varieties have been developed by Arkwright, the originator of this strain. This group is better known in Australia or England, and in the latter country these varieties are grown to some extent in winter under glass.

The culture of sweet peas under glass has increased rapidly since 1902, when William Sim began to grow this flower extensively and has developed the modern methods. Today large greenhouses are specially constructed for the purpose of growing this flower, and the amount thus invested represents considerable capital.

Low or dark greenhouses are not suitable for raising sweet peas. Large, wide houses with side walls at least 6 feet high and with good top and side ventilation, are now built for sweet-pea growing. No beds or benches are required. If the soil in the greenhouse is not naturally good, it is removed to a depth of 2 or 3 feet and replaced with better earth. The soil is trenched 2 feet deep or deep trenches are dug in which to place composted soil in preparing to sow sweet peas. The soil should be made sweet by the addition of lime, and enriched by liberal applications of bone-meal. Each year the soil should be deeply prepared and manure worked into it before sowing.

The colors most in demand on the market are pink and white, pink, lavender and white. The reds and orange colors are usually grown in less quantity. The

3747. Sweet peas started in pots, with supports.

3748. A sweet pea house at Detroit, Michigan.

varieties chosen should be those possessing good, clear, well-defined colors. The *Grandiflora* varieties are more productive, but do not bring so good a price in the larger cities as the waved varieties.

The early crop is sown about August 15, and the later crop during the latter half of September. The seeds are sown in drills where the plants are to stand, except the white-seeded varieties which are sown in sand and transplanted. The latter do not germinate well in soil, as a rule, but when treated in this way a good stand is secured. When the rows run east and west they should be 5 feet apart, and if they run north and south they may be placed as close as 3 feet.

The plants should be thinned to four plants to a lineal foot of row whether grown in single or double drills, and in planting from pots this rule should be observed.

Sweet peas are often grown after chrysanthemums, and for this purpose the plants should be started in 2½-inch pots. Two seeds may be planted in deep rose pots or in paper pots. The soil should be fibrous loam with the addition of fine old manure and sharp sand. The seeds are covered 1 inch deep, and the pots placed in a temperature of 55° to 60° F. for germination, after which the plants must be placed in a lower temperature to prevent them from becoming drawn.

The plants must soon have supports, and the best material to use under glass is string. If the rows are in line with the purlin posts, binder twine can be stretched from post to post on either side of the row thus inclosing the plants. These tiers of string will need to be as close as 6 to 8 inches at the bottom, but later as the vines grow may be as much as a foot apart. When the purlin posts are not in the row, temporary posts of iron pipe or 2- by 2-inch strips may be used. Wire netting is generally condemned by commercial growers, owing to the labor and expense connected with its erection and removal, and also because they think more crooked-stemmed flowers result. The vines supported by string can be easily removed at a minimum expense and the house quickly made ready for another crop.

The temperature in the autumn is often too high for sweet peas, and under such conditions the plants often show a tendency to flower when only 2 feet high; but, as a rule, it is usually better to remove all such flowers until the plants gain more strength. As far as possible, the night temperature should be from 40° to 45°, for if a higher temperature is given, the plants flower too soon and before they have made a good root-system. When the plants are from 30 inches to 4 feet high and showing buds, the temperature should be gradually raised to 52°. This is the highest temperature required for the *Grandiflora* varieties. When in bloom, the temperature should be 60° on cloudy days, and 68° on bright ones. The waved, or orchid-flowering, varieties require the same treatment previous to flowering, after which the night temperature should be 55°, 60° to 65° on cloudy, and 70° to 72° on sunny days.

Picking and packing.

Sweet pea flowers should be picked when the top flower is at least half open, unless the flowers are to be shipped a long distance, when they may be cut in a less fully developed state. The proper time to cut the flowers is in the morning, although this will depend upon the time the shipments can be made. The flowers

should be kept two to three hours in water before packing, and this will govern the hour of picking for the florist. The flowers must be packed dry, and if the outdoor flowers must be picked wet, they should be placed while in water in a warm current of air to dry the blooms. The flowers are made into bunches of nineteen to twenty-six spikes, according to quality. These are tied near the base of the stems, which are wrapped with waxed paper. The bunches are packed in shallow boxes with one, or at most two, layers of bunches packed in each box thus preventing the bruising of the flowers. The boxes often employed are 4 by 10 by 12 or 5 by 12 by 24 inches in depth, width, and length. The amount of wrapping on the boxes will depend on the temperature and other conditions at the time of shipment.

Exhibiting.

Exhibitors should keep the flowers off their vines until four or five days before the exhibition, and three days before this event a shade of cheese-cloth should be erected over the orange-, scarlet-, and blue-flowered

3749. Interior of sweet pea house.

varieties to prevent the scorching of the blooms. This shading must be removed after the exhibition flowers are cut. The spikes are cut so that all the flowers are fully open when they are judged. The ideal spike has a stem 12 to 18 inches long with four flowers. Twenty spikes loosely arranged so that each may be easily seen, is the proper number for a vase. The stems may be kept in the proper position by placing in the vases some 2-inch pieces of stiff reeds or grass stems. Some *Gypsophila* may be used in the vases if permitted by the rules of the competition. Arrange the vases of a collection of varieties so that colors do not clash and so as best to exhibit the merit of the blooms. The educational value of the exhibit is enhanced if each vase is neatly labeled with the name of the variety.

Insects and other pests.

Snails sometimes destroy sweet pea seedlings in frames or greenhouses, but can be prevented by scattering lime under the pots. The red-spider is sometimes troublesome in the greenhouse and outdoors, and can be controlled by the usual methods. The green aphid or "green-fly" attacks sweet peas under glass, but is easily controlled by regular fumigations of tobacco preparations. In the garden a larger green aphid, the clover aphid, is not infrequently found, but spraying with tobacco extract, nicotine, or kerosene emulsion

will usually destroy them. Plants that are frequently syringed with cold water are seldom infested with insects.

Fungous pests.

The most prevalent fungous pest affecting sweet peas under glass appears to be *Thielavia basicola*, or root-rot. Infected plants have little or no root-system, due to the fact that new roots are constantly destroyed. The leaflets often turn yellow with white edges, finally dying and falling to the ground. Sometimes one portion of the plant may be dry and dead while the remainder is green, although it does not grow or produce flowers. In fact, it is sometimes a mystery how a diseased plant can continue to live with its very limited root-system. There are some other root-rot organisms, but their action is similar and the method of control is the same for all—the removal of infected soil or sterilizing it.

The powdery mildew attacks greenhouse sweet peas at any stage of growth if the proper temperature is not maintained. The application of sulfur to the heating-pipes will check this disease. Care must be taken not to use the sulfur too strong or the flowers will be injured. Outdoor mildew usually does not appear until late in the season when the plants are failing.

Sweet peas grown in the open garden may be attacked by the root-rots above mentioned or by anthracnose and mosaic diseases, which may be serious. The former attacks the leaves, stems, flowers, and pods, but is most frequently found on the latter which are attacked at any stage of development. The affected parts wilt and die. The disease can be carried over winter upon the seeds. The prompt destruction of infected plants, as well as the burning of all old vines in the fall and the use of clean seed or treating the seed before sowing, will do much to lessen the danger from this disease. The mosaic disease, which may be allied to or identical with the trouble known as streak in England, is a rather baffling disease to the growers. It is distinguished by a yellow mottling of the leaves and stems of the plant. This is often accompanied by a curling of the leaves. The plants become stunted in growth and cease flowering if they have reached the flowering stage. It is a disputed point whether it is a bacterial disease or not, but it seems certain that the trouble is transmissible by the feeding of aphides. No remedy is known except the obvious one of keeping insects in check and destroying affected plants by fire.

The dropping of the young flower-buds either in the open or under glass is usually due to physiological conditions. Low temperature, lack or excess of plant-food, too much nitrogenous fertilizer, lack or excess of water are among the causes of this trouble. A. C. BEAL.

Growing sweet pea seed in California.

Up to about the year 1885, most of the sweet pea seed was grown in England, France, and Germany, and imported to this country; at that time the first attempt was made to grow the seed in California. This resulted in almost immediate success, and in 1900 more than 600 acres were devoted to the growing of the crop. Most of the sweet peas grown at this time were of the Grandiflora type and yielded an average of 1,100 pounds to the acre, sometimes in a good year even as much as 2,200 pounds. With the introduction of the Countess Spencer type of sweet pea, about 1904, however, the waved forms supplanted the Grandiflora type, the larger part of the acreage being now devoted to the Spencer type. Approximately 2,500 acres are now planted to the sweet pea.

The original Countess Spencer sweet pea was of a shell-pink color, but it was not fixed and many color sports were produced. At present there are about 150 distinct varieties of the Spencer type under about 460

different names, resulting from different growers finding the same sports, or from varieties which were not improvements on existing varieties of the same colors. The yield of seed to the acre of the Spencer type is much less than from the Grandiflora type, only about 250 pounds to the acre being obtained. This difference in yield is due to the structure of the flowers: in the Grandiflora type the keel is closed, not allowing the pollen to escape so that each variety must pollinate itself, and the varieties can be grown close together and yet remain true to color and type; in the Spencer type, however, the keel is open, allowing the pollen to be blown out, and, as a consequence, about 75 per cent of the flowers do not set seed; also the plants must be set far apart in order to keep them true to color and type.

A cross was made between the Spencer sweet pea and the winter-flowering sweet pea, resulting in the winter orchid-flowering sweet pea. This is a shy seedling than the Spencer, yielding only about seventy-five pounds to the acre. The flowers resemble the summer Spencer except that the growth is dwarf and the foliage more pointed. If sown in August under glass in the eastern states, they will bloom from November until late in spring. If sown outdoors, they will bloom three to four weeks earlier than the summer type, just before the extreme hot weather.

There are four types of sweet pea now grown in California: the summer Grandiflora, the winter Grandiflora, both of these being grown only on a small scale; the summer Spencer, and the winter orchid-flowering. In addition, the Cupid, which grows 5 to 6 inches high, is occasionally grown, only about 30 acres a season being devoted to it.

The raising of the sweet pea seed is usually on a large scale. Large tracts of land are plowed in autumn about 10 inches deep, either by horse-power or large tractors, before the beginning of the rainy season. The field is then carefully disced and pulverized and left to settle. If the rainy season begins as early as October, the fields should be harrowed again after the rain and the seeds planted. However, if the rains do not come until late, the seed must be sown in the dry soil, although they will not germinate so evenly. The most successful seeding is done between November and January. The seed is sown mostly by four- or two-row horse planters, being planted 30 inches apart and 3 inches apart in the rows, and 2 inches deep. Between each named variety, at least 10 feet must be left to prevent crossing.

After the seed is planted, the field must be kept in good condition by hoeing. After each rain the ground between the rows must be broken up. As soon as the plants are up, a horse cultivator may be used which breaks the crust 2 or 3 inches deep and 3 to 4 inches from the plants; but hand labor must be used to cultivate nearer the plants. This must be done after each heavy rain, sometimes five times being necessary. Irrigation is seldom practised, as 10 inches rainfall is sufficient for a good crop of sweet peas.

By the latter part of March and April the winter or early sweet pea will be in flower, and the summer or late sweet pea begins to bloom in May. Now must begin the process of thinning. No matter how carefully the seeds have been selected, there will be some "rogues" and these must all be removed. The best among these may be tagged and kept for stock seed to grow later on. All novelties and the stock seed for the next year are usually planted and taken care of by hand.

After the thinning has been done, the plants are left to themselves, no supports being given them, until the seed is ripe. These seeds are not evenly ripened and the cutting must be done when the larger part of the seed is ready to be harvested. The cutting is performed by a specially constructed ripper drawn by two horses and cutting two rows at once. As soon as cut,

the plants are piled in small heaps and left for several days to dry. They are then put in large piles to cure which takes from three to four weeks. As soon as all the seed is perfectly cured and sufficiently dry, the thrashing begins. This is usually performed by gasoline power, and the clean seed is run directly from the thrasher into the sacks.

ANT. C. ZVOLANER.

SWEET POTATO. The plant *Ipomœa Batatas*, grown for its large edible root-tubers (Fig. 3750). The origin is not definitely known (see page 1662, Vol. III), but it is probably tropical American. It is a widely variable plant in foliage, as shown by the leaf-forms in Fig. 3751. The top is herbaceous, form a running vine. Flowers and fruits are rarely seen.

Neither the acreage, production, nor the money value of the sweet potato crop give an adequate idea of its economic importance. In those parts of the earth's surface where it thrives, it forms an important food staple for the inhabitants, and thus occupies a position not accorded crops which, though of great money worth, do not contribute directly to the food-supply of the territory in which they are grown.

The sweet potato, being native to tropical and sub-tropical regions, is restricted in its range of cultivation

3750. A good hill of sweet potatoes.

more by climatic than by soil conditions, although its commercial cultivation is confined almost exclusively to sandy or loamy soils. It is, in fact, one of the staples of the southern states which thrives well on lands that have been considerably depleted by cropping with other plants, and one which can be made to produce a profitable return on light sandy soils carrying little humus, provided an adequate supply of plant-food in the form of commercial fertilizer is available. The ability of this plant to thrive and produce under such conditions, together with its great food value, which is considerably higher than that of the Irish potato, has served to advance it to the position of second place among the truck crops grown in the South and to seventh place among the standard agricultural crops of the nation.

Botanically the sweet potato belongs to the Convolvulus or morning-glory family. The edible part is the thickened root. It does not possess eyes or scars as do some other roots and tubers, but it possesses the ability to develop adventitious buds, which character is taken advantage of in reproducing the crop by vegetative means.

Roots to be used for seed purposes, selected at the time of harvest, are usually small, from 1 to 1¼ inches in diameter, of uniform shape, and characteristic of the variety. These roots are cured and stored under conditions most certain to insure an adequate supply of seed material, which, at the northern limit of the cultivation of the crop, is needed for bedding in April to insure a supply of "draws" for planting during the second and third weeks in May.

The seed-supply should not only be selected as above stated but it should be chosen from healthy plants and, in addition, should be carefully examined for disease. All specimens showing the slightest trace of decay or rot of any kind should be discarded.

The soil for the plant-bed, whether it be in the open or a manure- or fire-hotbed, should be free from contamination—preferably sterilized. If such precautions are observed, the first step in the insurance of the crop against loss from rot either in the field or in the storage house has been taken. Young sprouts which grow from the bedded seed roots are known as "draws" or "sets." These are chiefly used for planting in the field, but roots, or pieces of roots, may be and sometimes are used. In the warmer sections where seasons are long, it is a common practice to grow enough early draws or sets to plant an area large enough to give a sufficient quantity of vine cuttings to plant the commercial area. This is a good system as it insures disease-free plants, so far as the root-rots are concerned, for setting the field. An even closer approach to a let-alone system is followed in some sections. Instead of harvesting and storing seed and propagating sets, a portion of last season's crop is allowed to remain unharvested over winter and it is from the volunteer plants of such an area that a supply of vine cuttings for the commercial plantation are secured.

Sweet potatoes are for the most part long-stemmed, creeping, or viny plants. They can be planted in hills but are more often set on parallel ridges thrown up 30 to 36 inches apart. The ridges are often made by throwing two furrows together over a trench in which well-rotted stable-manure has been scattered, or in which commercial fertilizer containing a liberal percentage of potash has been placed. On such ridges the draws are usually planted, either by the use of a hand dibble, tongs, or transplanting machine, 14 to 16 inches apart.

The subsequent culture consists in keeping the area free of weeds with horse-drawn implements as long as the growth of the plants will permit even by the use of a vine-lifter, after which all large weeds are removed by hand.

The signal which summons all hands to the sweet potato harvest is the first frost which causes the leaves to blacken. The home-garden plantation will be harvested with potato forks or with a turning plow after the vines have been cut away with a hoe, but the commercial area will be entered with a special digging-plow with rods in place of a moldboard and two rolling coulters so arranged on a cross-piece fastened to the beam of the digger that they cut the vines on either side of the ridge, thus preventing their interference with the operation of digging. As soon as the roots have been turned out and have dried in the sun, they should be carefully gathered, so as to avoid breaking or bruising, into one-half- or five-eighths-bushel hampers and hauled on spring wagons to the curing and storage house. In placing the roots in the house, care should be exercised to avoid breaking or bruising them. Some growers spread layers of pine straw between each 12- or 15-inch layer of roots placed in the storage house. This practice is less common at the present time since especially designed storage houses have come into general use.

The storage houses in most general use both North and South are frame structures built entirely above ground, although there are a few houses at the North that possess a basement or semi-basement story used for the storage of sweet potatoes. These frame structures are so built that their contents are exposed in the least possible degree to outside changes of temperature. While the buildings are not insulated, they are provided with paper between the studding and sheathing, between the sheathing and the clapboarding, and on the inside under the sheathing. In the more exposed situations, either back plaster or a strip of paper is used between

the studding in addition to the construction above noted. The floors as well as the ceilings are made as nearly frost-proof as possible and to add still greater safety the roots are not placed on the main floor of the building itself but upon slat floors raised at least 2 inches off the main floor. Besides adding a factor of safety against frost, these slat floors serve another important function, that of facilitating the distribution of heat throughout the heap of roots during the curing process. The partitions between the bins should also be double-slatted partitions in order to act as ventilators or chimneys so that the ventilation of the material in the storage may be insured as well as more rapid and more uniform curing.

The curing of sweet potatoes at harvest-time is of equal importance with a proper storage room, good ventilation, and the maintenance of a proper storage temperature subsequently. As the sweet potatoes come from the field, they should be placed in the bins in layers distributed evenly over the surface, and during the time the house is being filled and for a period of ten days or more thereafter the temperature of the storage house should be maintained at 85° to 90° F. both night and day. After this drying or curing period, the temperature should be gradually reduced, but at no time during the storage period should it fall below 45° F. The temperature which has proved most satisfactory for holding the roots after the curing period is 50° F. While sweet potatoes can be successfully stored in hampers or crates, most commercial storages depend on the use of bins with slat floors separated by hollow slat partitions. A convenient arrangement is so to construct the storage that each bin holds one car-load or other unit quantity, depending on marketing facilities. In no case should sweet potatoes once placed in storage be rehandled or disturbed in any way until the contents of that particular receptacle, be it hamper, crate, or bin, is to be prepared for immediate delivery to the market. Sweet potatoes will not tolerate sorting or handling of any kind while in storage. The successful keeping of sweet potatoes in storage, therefore, depends on care in using disease-free seed or sets, careful handling of the roots from field to storage, a frost-proof storage provided with adequate heat for curing and ventilators for insuring rapid change of air during the curing-period as well as at subsequent periods when atmospheric conditions demand it, and the load of the house so placed, at time of storing, that any given unit may be discharged without disturbing the remainder of the material in storage. At harvest-time, and at all subsequent periods, except in severe weather when there is liability of injury from frost, sweet potatoes can be distributed in double-headed or burlap-covered, ventilated barrels. Such containers are economical, are more convenient to handle than crates or hampers, and form a satisfactory market unit. Bags should never be used. In cold weather when perishable freight or express is liable to frost-injury, strong hampers holding

one and one-half bushels or one-half barrel are often used as containers for sweet potatoes. Such packages are prepared for shipment by first lining them with a tough grade of paper, and, after the container has been filled and covered, wrapping it with a similar material. One of the great handicaps to the sweet potato industry at the present time is the highly perishable nature of the crop, making it difficult for those who do not have the best of facilities to market the crop during severe weather except to nearby markets.

There are two important types of sweet potatoes grown in the United States, one with a dry mealy flesh and another with a flesh of a soft, moist, sugary consistency when cooked. The northern markets generally prefer the dry mealy varieties with yellow color, while the soft, moist sorts, either light or deep yellow in color, are preferred by the southern markets. The commercial grower will therefore grow the sort or sorts demanded by the markets in which he expects to dispose of his product. His own likes and dislikes should not be given any weight in choosing market sorts.

Among the dry mealy-fleshed sorts may be mentioned Big Stem Jersey, Yellow Jersey, Early Carolina, and Triumph; characteristic representatives of the other class include such sorts as Nancy Hall, Georgia, Pumpkin Yam, Dooley, and Porto Rico.

SWEET SCABIOUS: *Scabiosa*. Sweet-scented Shrub: *Calycanthus*. S.-Sop: *Annona squamosa*. S. Sultan: *Centaurea moschata*. S. Vernal Grass: *Anthoxanthum*. S. William: *Dianthus barbatus*.

SWERTIA (named for Emanuel Swert, a bulb-cultivator of Holland and author of "Florilegium," 1612). Also spelled *Sweet-tia*, *Gentianacæ*. Erect, simple or branched, perennial or annual herbs, some of which are hardy, others adapted to the greenhouse; mostly border or rock-garden plants.

Leaves opposite, or radical in the perennial species, long-petioled, some of the cauline lvs. sometimes alternate; fls. blue, rarely yellow, arranged in racemose panicles or laxly corymbose; calyx 4-5-parted, segms. linear or lanceolate; corolla-tube very short, rotate, glandular-pitted, lobes 4-5, overlapping to the right; stamens 4-5; ovary 1-celled: caps. dehiscent by 2 valves at the sutures.—About 85 species, widely scattered about the world but mainly from S. Asia.

A. *Nectariferous pits destitute of a fringe.*

diluta, Benth. & Hook. (*Ophelia diluta*, Ledeb.). A tender perennial about 1 ft. high: st. winged and angled, branching from near the base: lvs. glabrous, ovate-lanceolate, 3-nerved, rather obtuse, rounded at the base, short-petioled: fls. 4-merous, blue, in a dense, fastigate umbel; corolla-lobes ovate, rounded at the apex and bearing at the base a single ovate, nectariferous pit destitute of a fringe. E. Asia, Japan.

AA. *Nectariferous pits with a fringe.*

B. *Pits oblong.*

punctata, Baumg. Perennial: sts. ascending from the base, many-fld.: lvs. several, alternate, elliptic-oblong, acutish; lower attenuate to a broad petiole: fls. erect,

3751. Leaves of sweet potato.

greenish yellow, dark-spotted; corolla-segms. membranaceous, lanceolate, rather obtuse, pits in 2's, oblong, crested and fringed. S. E. Eu., Caucasus.

BB. *Pits orbicular.*

connata, Schrenk. Perennial: st. erect, many-flid.: lvs. oblong, acutish, lower attenuate to the petiole; cauline all connate at base: fls. erect, greenish yellow, dark-spotted; corolla punctate, segms. obtuse, apex denticulate; pits distant, very long-ciliate. Siberia.

perennis, Linn. A hardy perennial $\frac{1}{2}$ –1 ft. high: lower lvs. oblong-elliptical, long-petioled; st.-lvs. ovate-oblong, obtuse: fls. mostly 5-merous, blue to white, in a thyrse; corolla-lobes elliptical-oblong, acute, bearing at the base 2 orbicular nectariferous pits crested with a fringe. Colo., Utah, and northward; also in the alpine regions of Eu. and in Asia.—*S. perennis* is an alpine bog-plant and should be given a cool deep moist soil.

F. W. BARCLAY.

F. TRACY HUBBARD.†

SWIETÈNIA (named for Gerard van Swieten, 1700–1772). *Meliaceae*. Trees, sometimes grown in the warm-house, one of them yielding the mahogany of commerce: lvs. even-pinnate, very glabrous; lfts. opposite, petioled, obliquely ovate, long-acuminate: fls. small, in axillary or subterminal panicles; calyx small, 5-cleft; petals 5, spreading; staminal tube urn-shaped, 10-toothed, anthers 10; disk annular; ovary sessile, ovoid, 5-celled: caps. 5-celled, about 3 in. diam.—Three species, Trop. Amer. Intro. into S. U. S.

Mahágoni, Jacq. MAHOGANY. A large evergreen tree with hard dark red wood of well-known value: lfts. 6–10: fls. greenish yellow. Tropical regions of N. and S. Amer., W. Indies, and S. Fla. G.C. III. 54:437.—According to Mueller, the degree of endurance is not sufficiently ascertained. In Jamaica it hardly reaches an elevation of 2,000 ft. It requires rich soil. It is said that the tree will bloom at small size when grown in pots.

S. Chloroxyton, Roxbg.=*Chloroxyton Swietenia*.

F. W. BARCLAY.

SYÁGRUS: *Cocos*.

SYCAMORE in Europe is *Acer pseudoplatanus*; in America, *Platanus occidentalis*, although this plant should be called plane-tree. The sycamore of the ancients was a kind of fig known as Pharaoh's fig, *Sycamoros antiquorum*, or *Ficus Sycomorus* (for which see pages 1233, 1234, Vol. III).

SYCÓPSIS (Greek, *fig* and *appearance*, alluding to its resemblance to certain figs). *Hamamelidaceae*. Five species of evergreen shrubs or trees of China and the Himalayas, with generally oblong, entire or denticulate, stipulate lvs. and rather insignificant apetalous monoecious fls. with minute calyx-lobes in heads or short racemes: staminate fls. in heads surrounded by pubescent bracts; stamens 8, with a rudimentary ovary; pistillate fls. with an urceolate calyx inclosing the ovary; styles 2, slender, with decurrent linear stigmas: fr. a dehiscent pubescent caps., with 2 brown lustrous seeds. Only the following species is sometimes cult. for its evergreen foliage; also the staminate fls. with their rather large red anthers are attractive. It stands the winter with some protection or in a sheltered position at the Arnold Arboretum. Prop. is by seeds or by cuttings of nearly mature wood under glass with slight bottom heat. **S. sinensis**, Oliver. Shrub or small tree, to 20 ft.: lvs. short-petioled, elliptic-ovate to elliptic-lanceolate, acuminate, usually denticulate above the middle, glabrous or sparingly pubescent, 2–4 in. long: pistillate fls. in 6–12-flid. stalked heads; staminate fls. in small heads surrounded by brown pubescent bracts; anthers oblong, red, on slender filaments: caps. densely pubescent. Cent. and W. China. H.I. 20:1931; 29:2334, figs. 1–3.

ALFRED REHDER.

SYMBEGÒNIA (name refers to the union of parts of the flower). *Begoniaceae*. A few small herbs, all natives of New Guinea (Afr.), differing from Begonia in the tubular female fls.; the male fls. have the parts distinct. *S. fulvo-villosa*, Warb., for some time the only known member of the genus, appears to be the only species that has appeared in cult., but is apparently not in the trade: erect herb 8 in. or less high, with red-tinged st. and oblique lance-oblong strongly double-serrate green lvs.: female fls. pale yellow, with 5 spreading serrulate lobes and a 3-winged inferior ovary; male fls. of 2 separate sepals, and 12–20 stamens. B.M. 8409.

L. H. B.

SYMBIOSIS is the intimate association of two or more distinct organisms, with benefit to one only, or to both; commensalism; consortism; copartnership. In this association each organism is called a symbiont.

According to the character of the union, several kinds of symbiosis have been recognized: (1) Mutual antagonistic symbiosis (mutual parasitism), when two organisms are foes of each other, as certain bacteria and animals, the latter showing a "natural resistance;" also the syntropism of certain lichens with lichens. (2) Antagonistic symbiosis (true parasitism), when the host is partly or completely killed by the parasite, as the potato and the rot fungus (*Phytophthora infestans*); or galls (hypertrophies) produced on the host, as in the black-knot of plums; and in higher plants, which live at the expense of others, as the mistletoe (green) and the dodder (chlorophyllless). (3) Mutual symbiosis, when there is often reciprocal advantage; (a) nutricism, when one symbiont nourishes the other without apparently receiving any return, as the mycorrhiza and the roots of forest trees (mycosymbiosis); (b) mutualism, when a mutual benefit results from the union of two organisms capable of living separately, as the bacteroid and the roots of the Leguminosae; (c) individualism, when the symbionts are so intimately connected in their growth as to suggest a single individual, as the union of alga and fungus to form a lichen. By some this relationship of alga and fungus in the lichen thallus is regarded as helotism, or slavery, where the alga lives entirely indifferent to the fungus. The views of Bruce Fink, who considers the lichen to be a fungus with an alga associated with it, are widely different from the usually accepted views on the subject. (4) Prototrophy, the wet-nurse relationship, as in the lichen *Lecidea intrumescens*, which eventually gets its nourishment by means of a lodger, a different lichen. (5) Contingent symbiosis, when one symbiont lives in the interior of another for shelter, as Nostoc in the tissues of Hepaticae, Lemna, Cycas, Gunnera; and Anabaena in Azolla. Green plants live symbiotically with animals such as Spongilla, Hydra, and Convoluta. In Hydra, the green alga, known as Chlorella, is found in the endodermic layer and when the colorless eggs of the fresh-water polyp are almost mature a few of the green cells are found migrating into the protoplasm of the egg-cells.

JOHN W. HARSHBERGER.

SYMPHORICÁRPOS (Greek, *symphorein*, to bear together and *karpós*, fruit, referring to the clustered fruits). Sometimes spelled *Symphoricarpus*. Syn., *Symphoria*. *Caprifoliaceae*. SNOWBERRY. Ornamental shrubs grown chiefly for their attractive fruits.

Deciduous upright or rarely prostrate shrubs: lvs. opposite, entire, or on vigorous shoots often sinuately dentate or lobed, exstipulate: fls. short-pedicelled, in terminal or axillary clusters or spikes or sometimes solitary; calyx 4–5-toothed; corolla campanulate or tubular, 4–5-lobed; stamens 4–5, included or somewhat exerted, style slender with capitate stigma; ovary with 2 fertile and 2 sterile cells: fr. a 2-seeded berry.—About 15 species in N. Amer., south to Mex. and 1 in W. China; many of the American species are closely related and difficult to distinguish.

The snowberries are low or medium-sized shrubs with slender upright or decumbent stems, spreading more or less by suckers, with small generally oval or ovate leaves and small clustered, rarely solitary, white or pink flowers followed by attractive usually white, rarely pink, dark red or bluish black berries. The flowers are rather insignificant in most species except in *S. oreophilus*, *S. microphyllus* and allied species which bear larger tubular nodding flowers and are rather attractive when in bloom. The chief ornamental feature is the fruits which are usually white and retained far into the winter; among the handsomest are *S. albus* var. *laevigatus* with heavy clusters of snowy white fruits at the tips of the arching branches, and *S. orbiculatus* with dark red fruits densely clustered along the slender branches and remaining plump and fresh far into the winter, its foliage also remaining unchanged until severe frost sets in. Some species, as *S. albus*, *S. orbiculatus*, and *S. occidentalis*, are quite hardy North, while *S. mollis*, *S. rotundifolius*, and *S. oreophilus* are hardy as far north as Massachusetts; *S. microphyllus* is tender. They are

AA. Fr. white or pinkish.

B. Fls. campanulate.

c. Style and stamens exerted.

2. *occidentalis*, Hook. WOLFBERRY. Fig. 3752 Shrub with upright rather stiff branches, 1-4 ft.: lvs. oval or ovate, entire or undulate-crenate, thickish, grayish green and pubescent beneath, 1-3 in. long: fls. in axillary clusters or spikes $\frac{1}{2}$ -1 in. long; corolla campanulate, pubescent inside, pinkish white, $\frac{1}{4}$ in. long: fr. subglobose, white, about $\frac{1}{2}$ in. long. June, July; fr. Sept. Ill. and Mich. to Brit. Col. south to Colo. and Kans. G.F. 3:297 (adapted in Fig. 3752). G.C. III. 49:104. Gn. 75, p. 508.—*S. Hejleri*, Dipp. (*S. occidentalis* var. *Hejleri*, Dieck), is very similar and differs chiefly in the thinner lvs. less distinctly veined beneath and more often undulate-dentate and in the somewhat shorter stamens and style; it is possibly a hybrid between this and the following species, found in Colo.

cc. Style and stamens included.

3. *álbus*, Blake (*S. racemosus*, Michx. *Vaccinium album*, Linn.). SNOWBERRY. WAXBERRY. Shrub with upright slender branches, 1-3 ft. high: lvs. oval to elliptic-oblong, obtuse, pubescent beneath, on shoots often sinuately lobed, 1-2 in. long: fls. in terminal spikes or axillary clusters; corolla campanulate, pinkish, about $\frac{1}{4}$ in. long: fr. globose or ovoid, snow-white, $\frac{1}{4}$ - $\frac{1}{2}$ in. long. June-Sept.; fr. Sept.-Oct. Nova Scotia to Alaska south to Pa., Idaho, and Calif. Var. *laevigatus*, Blake (*S. racemosus* var. *laevigatus*, Fern.). Taller, to 6 ft., with glabrous usually larger lvs. and larger clusters of frs. Que. to Wash., south to Va., often escaped. L.B.C. 3:230. B.M. 2211. G.W. 8:115. Gn. 77, p. 527. C.L.A. 15:33. G. 29:169; 35:769 and G.M. 56:763 (as *S. mollis*). Var. *ovatus*, Rehd. (*S. ovatus*, Spaeth). A form of the preceding with broadly ovate, bluish green lvs. mostly about 2 in. long and $1\frac{1}{4}$ in. broad, rounded or nearly truncate at the base.—The snowberry generally cult. as *S. racemosus* is the var. *laevigatus*, while typical *S. albus* is sometimes grown as var. *pauciflorus*, but the true var. *pauciflorus*, Blake, is a low shrub with smaller lvs. with grayish white pubescence beneath and only 1-3 fls. at the end of the branchlets; it is found from Lake Superior to Alberta and south to Colo. and Ore., and is apparently not in cult.

4. *acutus*, Dipp. (*S. mollis* var. *acutus*, Gray). Low diffuse or procumbent shrub: branchlets velutinous or puberulous: lvs. elliptic to elliptic-oblong, acute at both ends, soft-pubescent, grayish or whitish beneath, often irregularly dentate, $\frac{1}{2}$ -1 in. long: fls. in terminal few-fl. clusters and solitary or in 2's in the axils below; corolla pinkish or white, about $\frac{1}{4}$ in. long: fr. subglobose, white, $\frac{1}{4}$ - $\frac{1}{2}$ in. long. June, July; fr. Aug., Sept. Wash. to Calif. west to Idaho, Colo., and N. Mex.

BB. Fls. tubular or funnellform; style and stamens included.

c. Anthers reaching about the middle of the corolla-lobes.

5. *rotundifolius*, Gray. Upright shrub, to 3 ft.: lvs. orbicular to elliptic, entire or lobed, usually puberulous above, grayish and pubescent beneath, $\frac{1}{2}$ -1 in. long: fls. in 2-5-fl. terminal clusters and axillary; corolla pinkish, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, the tube pubescent within: fr. white, subglobose. June, July. Wash. to Calif. and N. Mex.

6. *oreophilus*, Gray. Upright shrub, to 4 ft., with slender spreading branches: lvs. oval to elliptic, usually acutish, slightly puberulous above, grayish or whitish pubescent beneath, $\frac{1}{2}$ -1 in. long: fls. in terminal 2-5-fl. clusters and axillary; corolla pinkish, nearly $\frac{1}{2}$ in. long, the tube almost glabrous within: fr. white, ovoid. June, July. Ore. to Calif. and Ariz. I.T. 3:98.

cc. Anthers as long as corolla-lobes.

7. *microphyllus*, Kunth (*S. montianus*, Kunth) Upright shrub, to 3 ft.: branchlets glabrous or puberulous.

3752. *Symphoricarpos occidentalis*. ($\times \frac{1}{2}$)

excellent plants for borders of shrubberies and for covering the ground under trees, spreading more or less by suckers; they will thrive in almost any soil from heavy clay to dry gravelly banks. Propagation is readily effected by hardwood and by greenwood cuttings, by division, and also by seeds.

INDEX.

<i>acutus</i> , 4.	<i>mollis</i> , 4, and suppl.	<i>pauciflorus</i> , 3.

A. Fr. red: fls. campanulate.

1. *orbiculatus*, Moench (*S. vulgaris*, Michx. *S. parviflorus*, Desf. *S. Symphoricarpos*, MacMillan. *Symphoria conglomerata*, Pers. *S. glomerata*, Pursh). INDIAN CURRANT. CORAL BERRY. Shrub, 2-5 ft., with slender upright branches: lvs. oval or ovate, mostly obtuse, usually pubescent beneath, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. in dense and short axillary and terminal clusters or spikes; corolla campanulate, $\frac{1}{2}$ in. long; stamens and the hairy style included: fr. purplish red, subglobose, $\frac{1}{6}$ - $\frac{1}{4}$ in. across. July: fr. in Oct., Nov., long persistent. N. J. to Ga., Kans., and Texas, west to S. D.; sometimes escaped. Mn. 1, p. 84. Gn. 34, p. 280. G.C. III. 28:413. Var. *variegatus*, Schneid. (var. *aureo-reticulatus*, Zabel). Variegated with yellow.—One of the most desirable species on account of the long-persisting fr. and foliage.

lous: lvs. ovate, acute, rounded at the base, pubescent and bluish gray beneath, $\frac{1}{2}$ – $1\frac{1}{2}$ in. long: fls. in terminal clusters and axillary; corolla pinkish, $\frac{1}{8}$ – $\frac{1}{2}$ in. long, pubescent inside: fr. pink. Aug., Sept. Mex. B.M. 4975.

S. longiflorus, Gray. Allied to *S. oreophilus*: lvs. smaller and narrower, acute at both ends: fls. slender, $\frac{1}{2}$ in. long; style pubescent. Calif. to Utah and N. Mex.—*S. mollis*, Gray. Closely allied to *S. acutus*, but lvs. oval to suborbicular, obtuse. Calif. The plant cult. under this name is usually *S. acutus*.—*S. sintensis*, Rehd. Slender glabrous shrub, to 5 ft.: lvs. oval to rhombic-ovate, $\frac{1}{2}$ –1 in. long: fls. in terminal peduncled spikes; corolla campanulate, white; fr. bluish black, bloomy. W. China. Has proved hardy at the Arnold Arboretum.—*S. vaccinioides*, Rydb. Allied to *S. rotundifolius*: lvs. elliptic, acute at both ends, puberulous or glabrescent: fls. small. Wash. to Wyo. and Utah.

ALFRED REHDER.

SYMPHYÁNDRA (Greek, *anthers grown together*). *Campanulaceæ*. Perennial herbs with a thick caudex, most of them hardy.

Leaves broad, usually cordate, dentate, the radical ones long-petioled, the cauline alternate, few or small: fls. usually nodding, rather large, racemose or laxly paniced, white, yellowish or bluish(?); calyx-tube adnate, hemispherical or turbinate, limb deeply 5-lobed or -parted; corolla campanulate, 5-lobed; ovary inferior, 3-celled.—About 8 species from the Caucasus and Asia Minor and one reported from Korea. Its special botanical interest lies in the fact that the anthers are grown together into a tube, which character tends to annul the distinction between the Campanula and Lobelia families. Otherwise the genus is much like Campanula, and used for similar purposes.

A. *Calyx without appendages*.

Höfmannii, Pant. Much branched, 1–2 ft. high, pilose: branches decumbent: lvs. oblanceolate, acute, doubly dentate: fls. white, pendulous, $1\frac{1}{2}$ in. long, 1 in. or more across, borne in a large leafy panicle; calyx-tube hemispherical, without appendages, segms. large, leafy, cordate; corolla campanulate, hairy inside. Bosnia. B.M. 7298. Gn. 57, p. 303. G.C. III. 4:761. R.H. 1910, p. 285.—Under favorable conditions in England this plant has maintained a succession of bloom from July–Dec. In Amer. the plant is said to be liable to exhaust itself in blooming, thus behaving like a biennial. It has large fleshy roots, needs a dry position, and sows itself. A plant of good habit and well worth cultivating.

AA. *Calyx with appendages*.

armèna, A. DC. Perennial, rather pilose: sts. slender, erect and decumbent, about 6–12 in. high, branched above: lvs. coarsely and rather acutely dentate; lower long-petioled, cordate-ovate; upper minute, subsessile: peduncles filiform, 1-branched or somewhat corymbose, 3–5-fld.; calyx hirsute, segms. spreading triangular, acute, appendages very short, acute; corolla velvety narrowly campanulate, lobes short. Caucasus.

ossética, A. DC. Perennial, rather glabrous, about 6 in. or less high: sts. leafy, rather stout, incurved-pendulous: lvs. acutely double-dentate; radical rather long-petioled, subcordate, ovate or oblong-acuminate; intermediate lvs. sessile: peduncles filiform, stoutly or rather simply racemose: fls. pale blue; calyx glabrous, segms. very broadly lanceolate, acuminate, appendages acuminate and short; corolla glabrous, tubular-campanulate. Caucasus.

S. pendula, Bieb. Perennial, pilose: sts. fleshy, 6–12 in. high: lvs. orenate-dentate, lower ovate, cordate, long-petioled; intermediate lvs. oblong, acute, cuneate, short-petioled: fls. simply racemose, yellowish white; calyx canescent-tomentose, appendages acuminate: corolla campanulate, whitish-tomentellous. Caucasus. F.W. 1877 289.—*S. Wanneri*, Heuff. Perennial, hispidulous: sts. 1–3, ascending, 6 in. or more high: lvs. oblong-lanceolate, acutely serrate or somewhat lacinate; radical long-attenuate to the petiole; cauline attenuate to the base, sessile: infl. thyrsoidly branched, branches 1–3-fld.: fls. blue-violet, large, nodding; calyx-tube hemispherical, segms. broadly and elongated-lanceolate, not appendaged; corolla long-campanulate. S. E. Eu. Gn. 65, p. 410.

F. TRACY HUBBARD.

SYMPHYTUM (Greek, *to grow together*, in reference to the supposed healing virtues). *Boraginaceæ*. COMFREY. Erect often hispid herbs, usually hardy in all but the far North, sometimes grown for the variegated foliage of some species.

Roots sometimes tuberous: lvs. alternate or several radical ones; the cauline sometimes decurrent; the upper sometimes strongly approximate, almost opposite: cymes terminal, usually single or twice bifid or simple unilateral racemes: fls. yellowish, blue, or purplish, pedicelled; calyx 5-cleft or -parted, lobes or segms. linear; corolla broadly tubular, lobes 5, very short; stamens 5; ovary distinctly 4-lobed: nutlets 4, obliquely ovoid, erect, rugose.—About 25 species, Eu., N. Afr., and W. Asia. Monographed by C. Bucknall in Journal of the Linnean Society, vol. 41 (1913). Of easy cult. in any good soil. The shade of overhanging trees is not objectionable. When grown for the beauty of the variegated foliage, the flowering sts. may be removed with advantage. Useful in borders.

A. *St. branched: fls. generally numerous*.

B. *Calyx divided to or below the middle*.

c. *Lvs. decurrent on the st.*

officinale, Linn. (*S. bohémicum*, F. W. Schmidt). Perennial, about 3 ft. high: root thick: st. branched,

3753. *Symphytum asperum*.
($\times \frac{1}{2}$)

white-pilose: lvs. slightly pilose, basal and lower cauline ovate-lanceolate, upper oblong-lanceolate, all broadly decurrent at base: fls. white, yellowish, purple, or rose, in drooping cymes. Eu., Asia. Var. **argenteum**, Hort., is offered in the trade as growing 2 ft. high, with silver-variegated foliage and drooping blue fls. Var. **aureum**, Hort., is offered in the trade as a golden variegated form growing 2 ft. high. Var. **coccineum**, Hort. (*S. coccineum*, Hort. ex Schlecht.), is offered in the trade as a scarlet-fld. form. Var. **lilacinum**, Hort., is offered in the trade. Var. **purpureum**, Pers. (*S. officinale* var. *bohémicum*, Don), has reddish purple fls. Eu. Var. **variegatum**, Hort., has lvs. widely margined with creamy white. F.S. 18:1901–1902.

cc. *Lvs. not decurrent*.

d. *Calyx-segms. obtuse: upper lvs. subpetiolate*.

asperum, Lepech. (*S. asperum*, Donn). PRICKLY COMFREY. Fig. 3753. Perennial, $2\frac{1}{2}$ –5 ft. or even more high: root thick: st. branched, uncinate: lvs. hispid or prickly on both surfaces, ovate or elliptical, acuminate; lower petioled base cordate or rotundate; upper subpetioled, base cuneate: fls. at first rose then blue, smaller than those of *S. officinale*. Russia, Caucasus, Persia. B.M. 929.—Has some forage value. There are horticultural forms with yellow-variegated or -margined lvs. known as *S. asperum* *aureo-variegatum*, and *S. asperum* var. *variegatum*.

DD. *Calyx-segms. acute: upper lvs. sessile*.

peregrinum, Ledeb. Perennial, about $3\frac{1}{2}$ ft. high: st. erect, tall, branched, prickly, prickles slightly retrorse: lower lvs. long-petioled, elliptic-lanceolate, acuminate, about $10 \times 4\frac{1}{2}$ in.; upper lvs. sessile, all

softly hispid; petioles decurrent: fls. sky-blue; buds pinkish; calyx 5-parted almost to the base, segms. triangular-lanceolate; corolla-tube angled, constricted at the middle, upper part somewhat campanulate, mouth 5-cleft. Caucasus. G.C. III. 50:127.—Closely related to *S. officinale*, may be a hybrid.

BB. *Calyx not divided to the middle.*

caucasicum, Bieb. Perennial, 1–2 ft. high, branched, softly pilose-hirsute, grayish: st. erect: lower lvs.

3754. Skunk cabbage (*Symplocarpus foetidus*), as the hoods come up in spring. ($\times \frac{1}{2}$)

oblong, attenuate to the petiole; upper lvs. narrowly and shortly decurrent: fls. paniculate-corymbose, blue; calyx viscidulous and setulose; corolla tubular-funnel-form, lobes shortly and broadly ovate. Caucasus.

AA. *St. simple or nearly so: fls. generally few.*

B. *Lvs. nearly glabrous.*

cordatum, Willd. Perennial: st. simple, glabrous: lvs. rather glabrous, subrotund-cordate, acuminate, radical long-petioled; cauline short-petioled; uppermost sessile, ovate-lanceolate: fls. yellowish white, in a few-fl. raceme; calyx somewhat 5-parted, lobes lanceolate; corolla funnel-form-tubular. Hungary.

BB. *Lvs. hispid.*

grandiflorum, DC. Perennial, about 1 ft. high: st. rather simple, base glabrate, otherwise reflex-spreading, hispid: lower lvs. long-petioled, subcordate-ovate, acute, decurrent along the petiole; uppermost lvs. opposite, oval, decurrent on the st.: fls. yellowish white, in a few-fl. raceme; calyx lobed below the middle, lobes linear; corolla-lobes broad and obtuse. Caucasus. G.W. 7, p. 294.

F. TRACY HUBBARD.

SYMPLOCÁRPOS (Greek, referring to the aggregate fruit). *Araceæ*. *Spathyèma* is the older name, but the other is retained by the "nomina conservanda" list of the Vienna rules. **SKUNK CABBAGE**. A hardy swamp-loving perennial herb which pushes up its hooded spathes in very early spring or even before the first of January in favored situations.

Spadix globose or oblong, entirely covered by fls., the ovaries of which are embedded in the spadix; perianth of 4 hooded sepals; anthers 2-celled; style pyramidal, 4-sided; ovary 1-loculed, with a solitary, suspended, anatropous ovule: berries in large heads, 1-seeded.—Only one species. See Krause, in Engler's *Pflanzenreich*, hft. 37 (IV. 23 B), 1910.

The spathes are 3 to 6 inches high, usually grow in clumps, and the variation in their coloring is a never-failing delight. They are mottled with purplish brown and greenish yellow, the former color sometimes becoming bright red, the latter ranging from dark green to bright yellow. These spathes are produced several weeks before the leaves appear, and they inclose odd flowers which are described below in detail. Just when the skunk cabbage flowers is a matter of some debate; the sta-

mens are generally out in February or March. The hoods retain their beauty for months. In April or May they decay and the strong-growing leaves soon attain a height of 1 to 3 feet and a breadth of 1 foot or more. All parts of the plant give a strong skunk-like odor, but only when bruised. Skunk cabbage is offered by dealers in hardy plants, as also by collectors. Its hardness and bravery have been celebrated by outdoor writers from Thoreau to the present day. The question of its pollination has been much discussed. It was long supposed to be pollinated by the action of the carrion flies which are attracted by its odor. However, Trelease has shown that the bees are busy with the pollen while the plant is in flower and that the carrion flies mostly come later.

foetidus, Linn. (*Spathyèma foetida*, Nutt.). **SKUNK CABBAGE**. Fig. 3754. Lvs. numerous, 1–3 ft. long, 1 ft. wide, ovate, strongly nerved: spathe preceding the lvs., colored as described above: fr. ripe Aug., Sept. Nova Scotia to Minn., south to Fla. and Iowa; also in Asia. B.M. 836 (as *Pothos foetida*); 3224. V. 23:186. A.G. 14:367.

WILHELM MILLER.

SÝMPLOCOS (Greek, *symplocos*, entwined or connected, the stamens being connate at the base). Including *Hopèa* and *Lòdhra*. *Styracàceæ*. Ornamental woody plants grown chiefly for their attractive flowers and fruits.

Deciduous or evergreen trees or shrubs: lvs. alternate, entire or serrate, exstipulate: fls. perfect or sometimes polygamous, in terminal or axillary racemes or panicles, rarely solitary; calyx 5-lobed, imbricate, corolla 5-lobed or 5-parted, often split almost to the base, rarely consisting of 2 whorls; stamens numerous, rarely few, usually connate at the base, and often more or less adnate to the corolla; style filiform; ovary 2–5-loculed, inferior: fr. a drupe with a long 1–5-seeded stone.—About 285 species, widely distributed through the tropical regions except Afr.; only a few outside the tropics. Monograph by Brand in Engler's *Pflanzenreich*, hft. 30 (IV. 241), 1907. Several species have medicinal properties; *S. tinctoria* yields a yellow dye.

Of the numerous species only *S. paniculata* which is

3755. *Symplocos paniculata*. ($\times \frac{1}{2}$)

hardy as far north as Massachusetts, is generally cultivated; it is a shrub or small tree with abundant white flowers in small panicles, appearing in spring, and with bright blue berry-like fruits in autumn. It thrives in well-drained soil and sunny position. The half-evergreen *S. tinctoria*, which seems not hardy north of its

3756. *Synadenium Grantii*. ($\times \frac{3}{8}$)

natural habitat, prefers moist soil and shady situation. The evergreen species are all tender and little known in cultivation. Propagation is by seeds, which usually do not germinate until the second year, and by greenwood cuttings under glass; also by layers.

paniculata, Wall. (*S. cratægoides*, Buch.-Ham. *Lodhra cratægoides*, Decne.). Fig. 3755. Deciduous shrub or

sometimes tree, attaining 40 ft., with slender, spreading branches, forming an irregular open head: young branches pubescent: lvs. short-petioled, oval or obovate to oblong-obovate, acute or acuminate, sharply serrate, distinctly veined beneath and more or less pubescent at the veins, rarely glabrous, $1\frac{1}{2}$ –3 in. long: fls. white, fragrant, $\frac{1}{8}$ – $\frac{1}{2}$ in. across, with spreading, oblong-oval petals in panicles $1\frac{1}{2}$ –3 in. long: fr. usually 1-seeded, oval, blue, about $\frac{1}{2}$ in. high. May, June. Himalayas to China and Japan. G.F. 5:89 (adapted in Fig. 3755). M.D.G. 1901:100, 101. S.I.F. 2:68. G. 33:425.

tinctoria, L'Her. SWEET LEAF. HORSE SUGAR. Half-evergreen shrub or small tree, occasionally to 30 ft. tall: lvs. elliptic to oblong-obovate, acute to short-acuminate, undulate or obscurely serrate, lustrous above, pubescent beneath, 2–5 in. long: fls. sessile, $\frac{1}{2}$ in. across, yellowish, fragrant, in axillary dense clusters: fr. oblong, crowned with the persistent calyx-lobes, $\frac{1}{2}$ in. long, orange-brown. Spring. Del. to Fla. and La. S.S. 6:255, 256.

S. coccinea, Humb. & Bonpl. Evergreen tree: lvs. oblong, acuminate, crenulate, 3–5 in. long: fls. solitary, axillary, pink, 1 in. across, with 10 petals. Spring. Mex. R.H. 1846:281. F.S. 2:133. —*S. japonica*, DC. (*S. lucida*, Sieb. & Zucc.). Evergreen shrub or small tree, 20 ft. high: lvs. elliptic to oblong, acute, remotely serrate, glabrous, 2–3 in. long: fls. yellowish, in short, few-fl. racemes: fr. oblong, red. Spring. Japan. S.Z. 1:24. S.I.F. 2:66. A shrub which has been distributed by several botanic gardens under the name of *S. japonica* has proved to be *Pyracantha crenulata*. —*S. stricta*, Ker. Deciduous shrub, closely allied to *S. paniculata*: lvs. elliptic, acute, serrate, pubescent on both sides, $1\frac{1}{2}$ –2 in. long: fls. white, in short panicles; calyx-teeth acute. May, June. China. B.R. 710. —*S. sumuntia*, Buch.-Ham. Small evergreen tree: lvs. oblong-elliptic, acuminate, cuneate at the base, serrulate, glabrous, 3–5 in. long: fls. white, in short racemes: fr. oblong. Himalayas. Gt. 31:1075.

ALFRED REHDER.

SYNADENIUM (Greek name, indicating the united involucre glands). *Euphorbiaceæ*. Thick-branched tropical shrubs, sometimes cult. in collections of succulents, having the generic characters of *Euphorbia*, except that the glands of the involucre are united so as to form a ring around the lobes.—About 10 species, chiefly in Trop. Afr. Prop. and treated similarly to the succulent euphorbias.

arborescens, Boiss. A shrub, up to 4 ft. high, the st. unbranched: lvs. obovate-cuneate, obscurely crenulate; midrib keeled and often denticulate: bracts puberulent: involucre yellow. S. Afr. B.M. 7184.

Grantii, Hook. AFRICAN MILK BUSH. Fig. 3756. A shrub 10 ft. or less high, branched: lvs. obovate-spat-

ulate, 3–4 in. long, obtuse; midrib rounded: cymes dichotomous, with tomentose bracts and red involucres. Trop. Afr. B.M. 5633. J. B. S. NORTON.

SYNÁNDRA (Greek, *together* and *anther*, referring to the connate anthers). *Labiataæ*. Hardy fibrous-rooted biennial herb, with the habit of *Lamium*, suitable for border planting: calyx campanulate, inflated; corolla-tube long, much expanded above and at the throat, the upper lip slightly arched, entire, the lower spreading and 3-cleft, with ovate lobes, the middle one broadest and notched; anthers approximate, in pairs under the upper lip, the 2 upper each with 1 fertile and 1 smaller sterile cell, the latter cells cohering together. One species, N. Amer. *S. hispidula*, Brit. (*S. grandiflora*, Nutt.). Hairy biennial, 1–2 ft. high, lower lvs. long-petioled, broadly ovate, cordate, crenate, thin; the floral lvs. gradually reduced to bracts, each with a single, sessile fl.: corolla $1\frac{1}{2}$ in. long, yellowish white. Shady banks of streams, Ohio to Ill., Tenn., and Va.

SYNCÁRPIA (Greek, *together* and *fruit*, referring to the head-like clusters of caps.). *Myrtaceæ*. Trees, one of which is intro. into Calif.: lvs. opposite, ovate, evergreen: fls. gathered in globose heads: peduncles 1-headed, lateral axillary or paniculate at the ends of the branches, rather small, white; calyx-tube adnate at base of ovary, turbinate or campanulate, segms. 4, rarely 5, persistent; petals 4, rarely 5; stamens many, free; ovary inferior, 2–3-celled: caps. adnate to the calyx and inclosed in it.—Two species, Austral.

glomulifera, Niedenzu (*S. laurifolia*, Ten.). TURPENTINE TREE. Lvs. broadly ovate to elliptic-oblong, obtuse or obtusely acuminate, 2–3 in. long, often appearing as if in whorls of 4: fls. 6–10 in a head, with 2–4 bracts of variable size under the head; calices connate at the base; petals broadly ovate or orbicular, less than 2 lines long; ovary 3-loculed; ovules several to each locule.—According to Von Mueller's Select Extra-tropical Plants, this tree attains a height of 200 ft., with a trunk often 30 ft. in circumference; it is of quick growth and well adapted for a shade tree. The wood is very durable and almost fireproof and is valuable for piles, railway sleepers, and shipbuilding. It takes a high polish and is used for flooring and cabinetwork. Offered in S. Calif.

F. TRACY HUBBARD.†

SYNDESMON (Greek, *bound together*, because the plant unites characters of *Thalictrum* and *Anemone*). *Ranunculaceæ*. RUE ANEMONE. Dainty perennial herb grown in wild borders for its carpet of beautiful leaves and attractive spring flowers.

Glabrous, from a cluster of tuberous roots: basal lvs. 2–3-ternately compound: involucre similar but sessile, the lfts. being stalked: fls. white or pink, in an umbel; pedicels slender; sepals thin, 5–10, petal-like; petals none; stigma sessile, truncate: achenes terete, deeply grooved.—A monotypic genus of E. N. Amer. Under the International Rules, *Anemonella* is the tenable name (*Anemonella thalictroides*). *Syn-desmon* was used earlier (1832 as against 1839), but in such a way as not to constitute publication as defined by those Rules, although it is tenable under the American Code. The plant should have been treated under *Anemonella* in this work.

The plants should be grown in partial shade. The soil should be moist and light or sandy. They should be left undisturbed for years. They will then form a carpet of great beauty. Propagation is by division of roots in spring or fall, but such division greatly weakens them and the plants for propagation should be taken from the edges of the beds.

thalictroides, Hoffmg. (*Anemone thalictroides*, Linn. *Thalictrum anemonoides*, Michx. *Anemonella thalictroides*, Spach). Fig. 3757. Plant 3–6 in. high: lvs. much like those of *thalictrum*: fls. resembling those of *Ane-*

CX. Commercial field of sweet potatoes in the Middle South.

mone quinquefolia, appearing before the basal lvs. March-June. Common in woods and open fields. L.B.C. 10:964. Gn. 35:408; 63, p. 277; 76, p. 305. J.H. III. 48:388. B.M. 866. I.H. 6:211. Var. *fiore-pleno*, Hort. Fls. double. Very pretty. L.B.C. 8:770. F.S. 11:1155. R.B. 11:205.

K. C. DAVIS.

SYNECHÁNTHUS (Greek, *continuous* and *flower*, alluding to the arrangement of the infl.). *Palmacæ*. Unarmed gregarious palms, grown in the warmhouse:

3757. *Syndesmon thalictroides*. (×½)

trunk slender, annulate, often stoloniferous: lvs. terminal, equally pinnatisect, segms. broad or narrow, membranaceous, acuminate, plicately nerved: spadices several, long- and slender - peduncled, the floriferous erect; spathes several, tubular, membranaceous, persistent: fls. green or the male purplish, minute, arranged in 1-2 rows in alternate elongated groups, the superior in the groups male, the inferior female: fr. reddish yellow, shining, ellipsoid, 1-seeded. Three species, Cent. Amer. and Colombia. *S. fibrosus*, Wendl.

Trunk 4 ft. high, green: lvs. 4 ft. long, erect and spreading; lfts. numerous, 1-1½ ft. long, spreading and rather pendulous, linear-lanceolate: spadices one-third as long as the lvs., the branches many, very slender, forked: fr. orange-red. Cent. Amer. B.M. 6572.

SYNGŌNIUM (Greek name, said to refer to the cohesion of the ovaries). *Aracæ*. Tropical American woody climbing or creeping plants, with milky juice and sts. rooting and lf.-bearing at the nodes: lvs. sagittate, becoming with age pedately 5-9-parted, on long petioles, with a persistent accrescent sheath: peduncles short: spathe yellowish or whitish green; tube small, ovoid, persistent; spadix shorter than the spathe: staminate fls. with 3-4 stamens, pistillate fls. with oblong-ovoid 2- or abortively 1-loculed ovary: seeds solitary in the locules, obovoid or globose, black.—About 10 species, W. Indies and Mex. to Brazil. Monographed in DC. Mon. Phan., vol. 2, 1879.

podophýllum, Schott. A tender creeping plant: lvs. becoming 5-7-pinnatisect, 4-6 in. long; petioles becoming 15-20 in. long: tube of the spathe 1-1½ in. long; blade of the spathe 2½ in. long, greenish outside, white within. Mex. The typical form is probably not in cult.

Var. *albolineatum*, Engl. (*S. albolineatum*, Bull.), has whitish costæ and lateral nerves. Offered by John Saul, 1893, presumably as a tender foliage plant.

F. W. BARCLAY.

SÝNTHYRIS (Greek, *together* and *little door* or *valve*, the valves of the capsule long adhering below to the short placentiferous axis). *Scrophulariæcæ*. Hardy herbaceous perennials, glabrous or pilose: rhizome thick: lvs. radical, petioled, ovate or oblong, crenate or incisely pinnatisect: peduncles scape-like, simple: fls. racemose or spicate, blue or reddish; calyx 4-parted, segms. narrow; corolla-tube very short or almost none,

subrotate-campanulate, 4-lobed or none; stamens 2: caps. compressed, obtuse or emarginate, 2-grooved.—About 15 species, natives of W. N. Amer. *Synthyris* is nearly related to *Wulfenia* of S. E. Eu. and the Himalayas, but the anther-cells are not confluent and the seeds are discoidal. In their native region they are summer-blooming plants with small purplish or flesh-colored spikes or racemes. Border plants.

reniformis, Benth. (*Wulfenia cordata*, Greene). A tufted plant about 1 ft. high: lvs. glabrous, orbicular-reniform, crenately incised, the small lobes sharply toothed, 1-3 in. diam.; petioles 3-6 in. long: infl. a raceme about 5 in. long with about 40 purple-blue fls. which are ¾ in. across; pedicels slender and short; calyx-lobes lanceolate. Ore. and Wash. Gn. 74, p. 165.—In England this plant is considered a winter bloomer; it flowers there in Feb. or March, occasionally Nov.

rotundifolia, Gray. Nearly or quite stemless: lvs. tufted, cordate-orbicular, 1-2 in. diam., long-petioled, doubly crenate, or crenate-incised, slightly pubescent: scape 4-6 in.: fls. few in a terminal raceme, blue or purple; calyx-lobes ovate, acute. Shady coniferous woods, Ore.

F. TRACY HUBBARD.

SYRÍNGA (of doubtful meaning; probably from *syrix*, pipe, because pipes are made from the straight stems of *Philadelphus* by removing the pith, and the name *Syringa* had been originally applied to *Philadelphus* but was transferred to the lilac. *Philadelphus* is still popularly called *Syringa*). *Oleacæ*. LILAC. Ornamental woody plants grown chiefly for beautiful and showy often fragrant flowers.

Deciduous, rarely evergreen (*S. sempervirens*), shrubs or small trees: lvs. opposite, entire or rarely pinnate, exstipulate: fls. in panicles; calyx small, campanulate, 4-toothed; corolla salverform, with cylindrical tube and 4-lobed limb; stamens 2; ovary 2-loculed: fr. a leathery, oblong or oval caps., loculicidally dehiscent, with 2 winged seeds in each locule. (Fig. 3758.) In *S. sempervirens* the caps. is fleshy, one-seeded, and drupe-like, though dehiscent.—About 30 species from S. E. Eu., to the Himalayas, N. E. Asia, and Japan.

The lilacs are mostly large shrubs with bright green medium-sized foliage and with large showy panicles of lilac, purple, or white flowers followed by brown insignificant capsules. They are among the most popular and ornamental flowering shrubs, and hardly any garden or park is found without them. The fragrance of the common lilac is very sweet, as also of *S. oblata* and *S. pubescens*. The strong odor of *S. chinensis* is not agreeable to everyone. *S. villosa* and *S. Josikæa* are almost scentless. *S. amurensis* and its allies have only a slight odor similar to that of the privet. Almost all species are hardy North, but *S. emodi* is somewhat tender; also, *S. pekinensis* is not quite so hardy as *S. amurensis* and *S. japonica*. The lilacs are very showy in bloom, especially when massed in groups, and groups as a rule are the more effective the fewer different varieties they contain. The mixing of species and varieties differing in habit and blooming season only spoils the effect, and so does too great a variety of colors. *S. japonica* is the only real tree of the genus; it attains a height of 30 feet. *S. vulgaris*, *S. amurensis*, and *S. pekinensis* sometimes grow into small trees or at least large shrubs 10 to 20 feet high. *S. persica* is one of the smallest species and seldom exceeds a few feet. The first in bloom are *S. affinis* and *S. oblata*, followed closely by *S. vulgaris*, *S. chinensis*, *S. pubescens*, *S. Julianæ*, *S. persica*, *S. vil-*

3758. Capsule of *Syringa vulgaris*. (×3)

iosa, *S. emodi*, and *S. Josikæa*; after the middle of June *S. amurensis* and *S. pekinensis* come into bloom, followed by *S. japonica* as the last, blooming in the North in the beginning of July. *S. amurensis* and *S. pekinensis* sometimes bloom sparingly a second time in fall. The foliage is bright green and handsome, but drops comparatively early in fall, especially in *S. japonica*, without assuming any fall coloring as a rule. In *S. oblata* the foliage turns to a deep vinous red and remains until November. In *S. pekinensis* it is retained until late in fall and finally assumes a purplish hue or turns pale yellow.

The foliage is not much attacked by insects, but a fungus, *Microsphaera alni*, late in summer often covers the whole foliage of *S. vulgaris* and also of *S. chinensis* and *S. persica* with a white mealy coat, while *S. oblata* is but rarely troubled with this fungus and the other species never. Much damage is sometimes done by a borer, *Trochilium denudatum*, which lives in the stems and branches of *S. vulgaris*, but is rarely found in any other species.

After blooming, the inflorescence should be removed if possible and the pruning be done as far as necessary. Pruning in winter or spring would destroy a large part of the flower-buds for the coming season. Lilacs grow in almost any kind of soil, but a rich and moderately moist one is the most suitable. They are easily transplanted at any time from fall to spring. *S. vulgaris* and its numerous varieties are the most popular of the lilacs on account of their early and profuse blooming, their sweet fragrance, and the variety of colors ranging from dark purple to lilac, pink, and white. The double-flowered varieties keep the blooms longer, but the panicles are less graceful and they usually do not bloom so profusely as the single ones; they also remain mostly dwarfed and have a more compact habit. The faded flowers do not fall off, but remain on the inflorescence; this gives the plant a very unsightly appearance if the faded panicles are not removed. W. J. Stewart suggests a word of warning against lilacs not on their own roots, because of the attacks of borers and the bad habit of suckering in some cases.

Some of the best single-flowered varieties are the following:

SINGLE-FLOWERED LILACS.—*White*: *Alba grandiflora*; *Alba pyramidalis*; Frau Bertha Dammann, A.F. 12: 1078; Madame Moser; Marie Legraye, one of the very best, B.H. 29:135; Princess Marie; Princess Alexandra is a favorite variety of this class in America.—*Blue, lilac, or pink*: Ambroise Verschaffelt, pale pink; Dr. Lindley, pinkish lilac, F.S. 14:1481; Géant des batailles, bluish lilac; Geheimrath Heyder, light lilac; Gigantea, bluish red; Gloire des Moulins, pale pink, G.M. 44:499; Goliath, purplish lilac; Lovaniana, light pink; Macro-stachya, light pink; Sibirica, purplish lilac; Trianon-iana, bluish lilac.—*Red*: Aline Mocqueris, dark red; Charles X (Caroli), dark lilac-red, A.F. 12:1076. F. 1873, p. 76; Marlyensis, sometimes called Rubra de

Marley, lilac-red; Rubra insignis, purplish red.—*Dark purple*: Philemon; Ludwig Spaeth (Andenken an Ludwig Spaeth, Louis Spaeth), very large panicles, the best of the dark varieties; Negro, deep violet-purple; Congo, deep wine red.

DOUBLE-FLOWERED LILACS.—*White*: Madame Abel Châtenay, compact panicles; Madame Casimir-Perier, large graceful panicles, one of the best; Madame Lemoine, large fls. in dense panicles; Obélisque; Virginité, white and pink.—*Blue, lilac, or pink*: Alphonse Lavallé, bluish lilac, A.F. 12:1077; Belle de Nancy, fls. pink with white center; Charles Baltet, lilac-pink; Condorcet, blue, A.F. 12: 1074; Doyen Keteleer, lilac-blue; Jean Bart, pinkish violet; Lamarck, pale lilac, large, rather loose panicles; Lemoinei, lilac-pink, B. H. 28:174; Léon Simon, changing from pinkish to bluish lilac. Gt. 43:1407; Maxime Cornu, pinkish lilac; Michel Buchner, pale lilac, large and very double fls.; President Carnot, pale blue.—*Purple*: Charles Joly, dark purplish red, one of the darkest; Comte Horace de Choiseul, lilac-purple; La Tour d'Auvergne, violet-purple.

3760. *Syringa villosa*.
× 1/2

The lilacs have been favorite forcing plants in France for more than a century and are nowadays among the most important cut-flowers during the winter season in France as well as in Germany and England. They are on the market from the end of September until they bloom outdoors. Charles X is considered one of the very best for forcing. Marlyensis, Marie Legraye, Alba virginalis, Ludwig Spaeth, and other varieties are also good for forcing. Of the double-flowered varieties the following have proved adapted for forcing: Madame Casimir-Perier, Madame Lemoine, Charles Baltet, Jean Bart, Léon Simon, *S. chinensis duplex*, and others. Either grafted plants or plants on their own roots are used. Both force equally well, but grafted lilacs can be grown into plants well set with flower-buds and suited for forcing in two or three years, while plants grown from cuttings require four to six years. Marlyensis is always used on its own roots and propagated either by seeds, cuttings, or division. Special attention must be given to pruning in order to have well-branched plants of good compact habit (see Fig. 1555, Vol. III, p. 1265). The lilac has nothing like the commercial importance for forcing in America that it has in Europe, but the appreciation of it for winter bloom is on the increase in this country.

Lilacs are generally forced in pots, being potted usually in July or in the fore part of August, that they may fill the pots with new roots before winter. Some growers pot the plants in spring or in the preceding fall. This practice is of especial advantage if the plants are intended for very early forcing. These early potted plants are then plunged into the ground outdoors, mulched, well watered and regularly manured; after June, when the young growth is almost finished, only enough water is given to prevent wilting. When the flower-buds have been formed, more water is given until they have reached their full size. It is essential to keep the plants rather dry in fall, so that the wood may ripen thoroughly and early. When the leaves have fallen off, the plants are stored away in convenient places, where they are sheltered from severe frost. Sometimes the lilac, especially *S. marlyensis*, is forced from balls of earth which are not potted, but this does not always give satisfactory results.

3759. *Syringa villosa*.

About three to four weeks is required to force the plants into bloom with the temperature recommended below. The first days after bringing the plants into the forcing-room, a temperature of 55° to 60° may be given, gradually rising to 78° to 88° and maintained as equally as possible until the panicles are fully developed and the first flowers begin to expand; then the temperature is lowered to 60° to 66°, and when the panicles are about half open the plants are transferred to a cool greenhouse. Hardening-off is essential to ensure good keeping qualities of the flowers. The red-flowered varieties are often forced in darkened rooms in order to have the flowers blanched or only slightly colored. The shade of color depends entirely on the time when full light is given and also on the temperature. Show plants in pots

3761. *Syringa vulgaris*.—The common lilac. ($\times \frac{1}{2}$)

should be grown in full light to have the foliage well developed. When the temperature is higher than 76°, frequent syringing is necessary. It is, of course, possible to force lilacs in a lower temperature, and this will even be advisable if the longer time required does not count. Full advice for commercial lilac-forcing is given by Fr. Harms in "Flieder und Asparagus," a book devoted almost exclusively to lilac-forcing.

Interesting experiments recently conducted have shown that the lilac is more readily forced when the plants are subjected to the influence of ether during forty-eight hours shortly before forcing. An account of these experiments by W. Johannsen is entitled "Das Ätherverfahren beim Frührreiben mit besonderer Berücksichtigung des Flieders." That the ether has a particular effect on the metamorphosis and regeneration of the albuminoids in the plant has been stated recently by other botanists also.

Lilacs may be propagated by seed, which is sown in spring. This method is usually practised only with the

more common typical species. The many varieties and rarer kinds are usually propagated by greenwood cuttings under glass in June (or in early spring from forced plants), by hardwood cuttings, by grafting, and also by suckers and division, especially in the case of *S. chinensis*, *S. persica*, and *S. vulgaris*. As a stock, *S. vulgaris* is mostly used and sometimes *ligustrum*. *S. japonica* will probably prove to be a good stock. *S. villosa*, though readily growing from seed and of vigorous habit, is not to be recommended. Budding in July and August is the most extensively practised method. Grafting is done either in April or May in the open or in February or March in the greenhouse on potted stock. Almost any kind of grafting may be employed as the lilac unites readily. Crown-grafting is to be preferred in order to avoid the troublesome suckers. Plants intended for forcing but deficient in flower-buds are sometimes grafted in October or early in November with branches well set with flower-buds and forced in January or later.

Forcing lilacs.—Most of the lilacs used by American commercial florists for forcing are imported. Care should always be taken to procure pot-grown plants, that is, plants that have been grown in pots the previous summer. The florist who wishes to grow his own plants should lift them in the field in April or before the growth starts and pot them without losing much root. Plunge them out-of-doors during summer and give them plenty of water. This treatment will insure a good growth and the check the plants receive from lifting will induce them to form new flower-buds. These plants will force with the greatest certainty. It is well to allow five weeks for the earliest forcing. A strong heat is necessary, beginning at 60° for the first few days and increasing to 75° to 80°, with a daily watering and syringing several times. After the flowers begin to open, the syringing can be discontinued and when

fully expedient the plants are better removed to a coolhouse, where they will harden off and be much more serviceable when cut. As the season advances, say March and April, less heat is needed. They will then force in any ordinary house where the night temperature

is about 60°F. The Persian lilac, on account of its abundance of bloom and delicate truss, is very desirable, but this must be forced almost in the dark to produce white flowers. Marie Legraye is for all purposes the most useful lilac which has been used for forcing. (Wm. Scott.)

KEY TO THE SPECIES.

- A. Tube of corolla much longer than calyx; anthers sessile, not exerted.
- B. Panicles on leafy branches, usually terminal: lvs. whitish beneath.
- C. Infl. upright.
- D. Anthers not exerted.
- E. Stamens inserted near the middle of the tube; corolla-lobes nearly upright. 1. *Josikæa*

- EE. Stamens inserted below the mouth of the tube; corolla-lobes spreading..... 2. *villosa*
- DD. Anthers exerted about one-half above the mouth: lvs. very white and glabrous beneath.... 3. *emodi*
- CC. Infl. nodding or pendulous: corolla-lobes little spreading..... 4. *reflexa*
- BB. Panicles from lateral buds, without lvs. at the base; terminal bud suppressed.
- C. Anthers dark violet, inserted much below the mouth: lvs. more or less pubescent beneath, at least while young.
- D. Branchlets and lvs. above glabrous..... 5. *pubescens*
- DD. Branchlets and lvs. above pubescent..... 6. *Julianæ*
- GG. Anthers pale: lvs. glabrous except in No. 7.
- D. Base of lvs. truncate or cordate.
- E. Lvs. roundish or broadly ovate.
- F. Young lvs. more or less finely pubescent: infl. loose..... 7. *affinis*
- FF. Young lvs. quite glabrous or minutely glandular: infl. dense..... 8. *oblata*
- EE. Lvs. ovate..... 9. *vulgaris*
- DD. Base of lvs. cuneate.
- E. Shape of lvs. ovate-lanceolate. 10. *chinensis*
- EE. Shape of lvs. lanceolate..... 11. *persica*
- AA. Tube short, little longer than calyx; stamens exerted: fls. white. (*Ligustrina*.)
- B. Base of lvs. narrowed: habit spreading..... 12. *pekinensis*
- BB. Base of lvs. usually rounded: habit upright.
- C. Under side of lvs. glabrous: lvs. abruptly acuminate: tall shrub.... 13. *amurensis*
- CC. Under side of lvs. more or less pubescent; lvs. rather gradually acuminate: tree..... 14. *japonica*

Section EUSYRINGA.

Group VILLOSÆ.

1. *Josikæa*, Jacq. Shrub, attaining 12 ft., with upright, stout, terete branches: lvs. broadly elliptic to elliptic-oblong, acute at both ends, finely ciliate, dark green and shining above, glabrous or pubescent on the midrib beneath, $2\frac{1}{2}$ –5 in. long: fls. violet, short-pedicelled or almost sessile, clustered, in rather narrow panicles 3–7 in. long; corolla with the half-upright lobes $\frac{3}{4}$ in. long; stamens inserted somewhat above the middle of the tube. June. Hungary. B.M. 3278. B.R. 1730.—Less handsome than most other species, but valuable for its late blooming season. Var. *pallida*, Hort., has pale violet fls.; var. *rubra*, Hort., reddish violet.

2. *villôsa*, Vahl (*S. Bretschneideri*, Lemoine. *S. emodi* var. *rosea*, Cornu). Figs. 3759, 3760. Bushy shrub, 8 ft. high, with rather stout, upright, terete and warty branches: lvs. broadly elliptic to oblong, acute at both ends, finely ciliate, bright green and dull above, pubescent usually only near the midrib, rarely glabrous beneath, 3–7 in. long: fls. pinkish lilac or whitish, short-pedicelled, in broad or somewhat narrow usually pubescent panicles, 3–7 in. long, rachis terete; lobes spreading, tube about $\frac{1}{2}$ in. long; stamens inserted near the mouth. May, June. China to Himalayas. R.H. 1888: 492; 1914, p. 333. G.F. 1:521. Gn. 39, p. 91. Gt. 44, p. 500. G.W. 16, p. 138. G. 13:519. A.F. 24:371. B.M. 8292.—A hybrid between this and the preceding species is *S. Hénryi*, Schneid. (*S. Bretschneideri hybrida*, L. Henry). Intermediate between the parents, but more similar to *S. villosa*: lvs. villous along the midrib: infl. large, to 10 in. long, more pyramidal and looser: corolla $\frac{3}{4}$ in. long, pale violet-purple, with the stamens just below the mouth. R.H. 1902:40. J.H.S. 27, p. 800.

"*Lutèce*" is scarcely different. Var. *eximia* (*S. Josikæa eximia*, Froebel) has compact large panicles of reddish rose fls. changing to light pink. G.C. III. 42:280. M.D.G. 1901:561. M.D. 1907, p. 262. "H. Zabel" is similar, but the fls. are reddish lilac.

3. *emodi*, Wall. (*S. villosa* var. *emodi*, Rehd.). Shrub, to 15 ft.: branchlets brownish or dark olive-green, dotted with pale lenticels: lvs. elliptic to oblong, acute at both ends, white and glabrous beneath, 6–8 in. long: infl. narrow, 3–6 in. long, with leafy bracts; rachis angular: corolla pale lilac or whitish, not pleasantly scented, tube $\frac{3}{8}$ in. long; anthers partly exerted; calyx obscurely lobed. Himalayas. B.R. 31:6. R.H. 1876, p. 368. Gn. 39, p. 106. R.B. 28:193.—Not quite hardy in Mass. There are varieties with yellow lvs., var. *aurea*, Simon-Louis, and with yellow-variegated lvs., var. *aureo-variegata*, Hort.

4. *reflexa*, Schneid. Shrub, to 12 ft.: branches gray or purplish gray, dotted with lenticels: lvs. ovate-oblong to lance-oblong, sometimes elliptic-obovate, acuminate, cuneate at the base, glabrous above, villous beneath chiefly along the veins, 3–5 in. long: infl. nearly cylindric, nodding or pendulous, 5–7 in. long and $1\frac{1}{2}$ –2 in. across; rachis, pedicels, and calyx sparingly villous or calyx nearly glabrous: corolla pinkish, $\frac{1}{2}$ – $\frac{3}{4}$ in. long with nearly upright lobes: fruiting panicles pendulous with reflexed, slightly warty oblong caps. W. China.—A remarkable species very distinct from all others by the pendulous panicles and particularly handsome before the fls. open because of the carmine color of the buds.

Group VULGARIS.

5. *pubescens*, Turcz. (*S. villosa*, Decne., not Vahl. *S. villosa* var. *ovalifolia*, DC.). Shrub, 6 ft. high, with slender, somewhat quadrangular glabrous branches: lvs. roundish ovate to rhombic-ovate or ovate, shortly acuminate, ciliate, dark green and glabrous above, 1–3 in. long: fls. pale lilac, fragrant, short-pedicelled, in ovate, not very large, but numerous panicles; tube very slender; anthers violet, inserted much below the mouth. May. N. China. G.F. 1:415; 6:266. B.M. 7064. G.C. III. 38:123 (as *S. villosa* var. *pubescens*).—Free-flowering shrub of graceful habit, with handsome dark foliage.

6. *Julianæ*, Schneid. Spreading shrub, to 6 ft.: branchlets villous: lvs. elliptic-ovate, acute or acuminate, cuneate at the base, short-pubescent above, pale and more villous-pubescent beneath, particularly on the veins, 1–2 in. long: infl. 2–4 in. long, rather loose; rachis and pedicels slightly hairy and like the glabrous distinctly toothed calyx purplish violet: corolla lilac-purple outside, fragrant, small, the spreading lobes white inside; anthers violet, inserted a little below the mouth. May,

3762. Winter twig of *Syringa vulgaris*, showing the absence of a terminal bud and the persistent dehiscent pods. ($\times\frac{1}{2}$)

June. W. China. B.M. 8423.—A handsome and distinct species similar to *S. pubescens*; the deeper color of the fls. is heightened by the purplish violet color of the whole infl.

7. *affinis*, L. Henry (*S. oblata* var. *alba*, Hort.). Slender, loosely branched shrub; lvs. broadly ovate, acuminate, truncate at the base, finely pubescent while young, particularly on vigorous shoots, on flowering branchlets sometimes glabrous or nearly so, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long and $1\frac{1}{3}$ – $2\frac{1}{3}$ in. broad; infl. slender and rather loose, $4\frac{1}{2}$ – $5\frac{1}{2}$ in. long; calyx distinctly 4-toothed; corolla white, tube $\frac{1}{2}$ in. long. May. N. China. Var. *Giraldii*, Schneid. (*S. Giraldii*, Lemoine, not *S. Giraldiana*, Schneid.). Lvs. usually more densely pubescent while young; infl. 5–6 in. long, fls. purplish lilac; rachis, pedicels, and calyx purple-violet. N. W. China. R.H. 1909, p. 335.—The earliest of the lilacs to bloom and the fls. do not suffer from frost as do those of *S. oblata*. Hybrids of var. *Giraldii* with *S. vulgaris* have been raised recently by Lemoine, which flower nearly two weeks before the earliest varieties of *S. vulgaris*; such are "Lamartine" with rose-mauve fls. and "Mirabeau" with rosy lilac fls.

8. *oblata*, Lindl. Shrub or small tree, 12 ft. high, rather compact; lvs. roundish ovate or reniform, often broader than long, cordate, short-acuminate, bright green, their margins usually reddish while young, $2\frac{1}{2}$ – $4\frac{1}{2}$ in. across; fls. pale lilac to purple-lilac, in dense subglobose or pyramidal panicles, 3–5 in. long; pedicels about as long as the distinctly toothed calyx. May. N. China. G.F. 1:221. A.G. 22:183. G.W. 5, p. 549. B.M. 7806. G. 36:355.—Next to the preceding species the earliest to bloom and handsome in fall with its vinous or russet-red foliage. A hybrid with the following species is *S. hyacinthiflora*, Rehd. Intermediate between the parents, with broadly ovate lvs., turning purplish in fall. Only known in the double form, var. *plena*, Lemoine. Many or perhaps most of the newer double-fl. varieties have originated by recrossing this form with varieties of *S. vulgaris*.

9. *vulgaris*, Linn. Figs. 3758, 3761, 3762. Upright shrub or small tree, 20 ft. high; lvs. ovate, truncate or slightly cordate, acuminate, bright green, 2–4 in. long; fls. lilac, blue, purplish, or white, in large panicles. May. S. E. Eu. to Caucasus and Afghanistan; sometimes escaped from gardens in the eastern states. B.M. 183. Gn. 53, p. 156. M.D.G. 1899:205. F.E. 22:5. R.H. 1903, pp. 126–128.—The most important of the older original varieties are the following: Var. *alba*, Ait., branches yellowish gray; fls. white; buds yellowish green; blooms a week earlier than the other varieties. A.F. 12:1081. Var. *cærulea*, Ait. Fls. blue, in rather loose panicles. Var. *rùbra*, Loud. Fls. purplish red, in large and rather dense panicles. Here belong also var. *marlyensis*, Hort., and Charles X. Var. *violacea*, Ait. Fls. violet-lilac, in rather loose panicles. Var. *plena*, Hort. With double fls. There are several varieties with variegated lvs., but these are hardly worth cultivating.

10. *chinensis*, Willd. (*S. persica* × *S. vulgaris*. *S. dubia*, Pers. *S. rothomagensis*, Loud. *S. varina*, Dum.-Cours.). Shrub, attaining 12 ft., with slender, often arching branches; lvs. ovate-lanceolate, acuminate, 2–4 in. long; fls. purple-lilac, red, or white, in large and broad panicles. May. Originated in 1777 in Rouen, France. R.H. 1883, p. 80. F. 1873, p. 76 (as *S. persica*). G.M. 44:498; 50:431.—Very free-flowering. Var. *alba*, Loud., with white fls. Var. *metensis*, Simon-Louis, with pale purplish fls. Var. *saugeana*, Loud. (var. *rùbra*, Lodd.), with deep purplish red fls. Var. *dùplex*, Lemoine, with double purplish lilac fls.

11. *persica*, Linn. Fig. 3763. Shrub, attaining 5–10 ft., with slender, arching branches; lvs. lanceolate, acuminate, $1\frac{1}{2}$ –3 in. long; fls. pale lilac or whitish, in rather loose, broad panicles, about 3–4 in. long; pedicels as long as or longer than calyx. May, June. Caucasus

to Afghanistan. B.M. 486. Var. *alba*, Loud. (*S. Steencruysii*, Hort.). Fls. white. Var. *rùbra*, Hort. Fls. red. Var. *laciniata*, Vahl (*S. pteridifolia*, *S. filicifolia*, and *S. pinnata*, Hort.). With pinnately lobed or pinnatifid lvs., of dwarfer habit and with smaller panicles. R.H. 1878, pp. 452, 453; 1883, p. 80; 1901, pp. 40, 41.

Section LIGUSTRINA.

12. *pekinensis*, Rupr. (*Ligustrina amurensis* var. *pekinensis*, Maxim. *Ligustrina pekinensis*, Regel). Large shrub, attaining 15 ft., with slender, spreading

3763. *Syringa persica*, one of the common lilacs. (× $\frac{1}{4}$)

branches, brownish red when young; lvs. ovate to ovate-lanceolate, usually narrowed at the base, acuminate, rather dark green above, pale or grayish green and glabrous beneath, 2–4 in. long, $1\frac{1}{2}$ in. broad; fls. yellowish white in large glabrous panicles, usually in pairs at the ends of branches; stamens about as long as limb. June. N. China. G.F. 3:165; 7:385. M.D.G. 1899:425.—Large shrub, of excellent habit, with handsome foliage retained until late in fall; flowers profusely only when older. Var. *péndula*, Hort. With very slender, pendulous branches.

13. *amurensis*, Rupr. (*S. ligustrina*, Hort. *Ligustrina amurensis* var. *mandshurica*, Maxim. *Ligustrina amurensis*, Regel). Shrub, attaining 12 ft., with spreading or upright branches; lvs. broadly ovate to ovate, usually rounded at the base, bright green above, pale or grayish green and glabrous beneath, 2–6 in. long, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. broad; fls. yellowish white, in large, rather loose glabrous panicles; stamens almost twice as long as limb. June. Manchuria. Gt. 12:396; 45, p. 64. G.F. 2:271. Gn. 12, pp. 623, 624. R.H. 1877, pp. 453–455.—Sometimes cult. under the name of *S. sibirica* or *S. sibirica alba*.

14. *japónica*, Decne. (*Ligustrina amurensis* var. *japónica*, Maxim.). Fig. 3764. Pyramidal tree, attain-

ing 30 ft., with upright branches: lvs. broadly ovate to broadly elliptic, rounded or slightly cordate at the base, shortly acuminate, pale green beneath, and usually pubescent when young, 3-7 in. long: fls. yellowish white, in very large pubescent panicles often 1 ft. or more long; stamens little longer than limb. June, July. Japan. B.M. 7534 and S.I.F. 2:33 (as *S. amurensis*). G.C. II. 25:561. Gn. 76, p. 356. G. 29:549. G.F. 2:293, 295. M.D. G. 1899:424; 1907:381. Gt. 37:217. Mn. 4, p. 5; 7, p. 167. R.H. 1894, p. 325.—Very desirable free-flowering tree and quite hardy N. Var. *argentea*, Temple, has the lvs. variegated with silvery white.

S. albo-rosea, N. E. Br. . . *S. tomentella*.—*S. Koehneana*, Schneid. (*S. velutina*, Hort., not Komarov). Allied to *S. pubescens*. Young branchlets puberulous: lvs. oval to oblong-lanceolate, pubescent on both sides, 2-3 in. long: infl. 3-4 in. long, pubescent: fls. pale lilac. China.—*S. Komarovii*, Schneid. Allied to *S. villosa*. Lvs. oblong-ovate, pubescent beneath, 4-6 in. long: infl. narrowly pyramidal, to 6 in. long, pubescent: corolla lilac; anthers partly exerted. W. China. Var. *Sargentiana*, Schneid. Branchlets slightly pubescent: infl. usually somewhat larger: corolla purple; anthers usually scarcely exerted. W. China.—*S. Meyeri*, Schneid. Allied to *S. pubescens*. Small shrub: lvs. elliptic-ovate, sparingly pubescent beneath: infl. rather dense: fls. lilac with very slender tube over $\frac{1}{2}$ in. long. N. China. Blooms when scarcely a foot high.—*S. pinnatifolia*, Hemsl. Allied to *S. persica*. Lvs. pinnate, 2-3 $\frac{1}{4}$ in. long with 9-11 sessile and decurrent lfts.: infl. slender, about 2 in. long; fls. whitish pink, the tube $\frac{1}{2}$ in. long. W. China. G.C. III. 55:269.—*S. Rehderiana*, Schneid. Allied to *S. villosa*. Branchlets tomentose: lvs. elliptic, pubescent on both sides, 3-4 in. long infl. broadly pyramidal, to 7 in. long, villous: fls. white. W. China.—*S. Sargentiana*, Schneid. = *S. Komarovii* var. *Sargentiana*.—*S. sempervirens*, Franch. Shrub, to 4 ft., glabrous: lvs. persistent, coriaceous, broadly oval, obtuse or acutish, 1-1 $\frac{1}{4}$ in. long: fls. white, $\frac{1}{4}$ in. long, in dense panicles 2-3 in. long: fr. fleshy, dehiscent. S. W. China. It looks more like a privet than like a lilac; not hardy N. —*S. Sweginowii*, Koehne & Lingelsh. Allied to *S. villosa*. Lvs. ovate, usually rounded at the base, pubescent beneath only near the veins, 2-4 in. long: infl. to 10 in. long, with purple rachis: fls. yellowish white suffused with pink, fragrant, the tube about $\frac{1}{2}$ in. long. E. Asia. G.C. III. 57:345. M.D. 1910, p. 112.—*S. tomentella*, Bur. & Franch. (*S. albo-rosea*, N. E. Br.). Allied to *S. villosa*. Branchlets glabrous or short-pubescent: lvs. elliptic to oblong-

lanceolate, more or less pubescent beneath, 1-3 $\frac{1}{2}$ in. long: infl. dense, to 7 in. long, puberulous; fls. lilac-pink; tube over $\frac{1}{2}$ in. long. W. China. M.D. 1910, p. 112.—*S. velutina*, Hort., not Komarov = *S. Koehneana*. The true *S. velutina*, Komarov, is apparently not in cult.; it differs chiefly in its larger lvs. and the glandular petioles and infl.—*S. Wilsonii*, Schneid. Allied to *S. villosa*. Lvs. elliptic-ovate, to elliptic-lanceolate, pubescent beneath near the veins, 2 $\frac{1}{2}$ -5 in. long: infl. broad, to 6 in. long, glabrous or nearly so; fls. white or lilac, tube about $\frac{1}{2}$ in. long. W. China.—*S. Wolfii*, Schneid. Allied to *S. villosa*. Lvs. elliptic-oblong, nearly glabrous: infl. to 12 in. long: fls. lilac, fragrant, $\frac{3}{4}$ in. long. N. China. Remarkable for its very large panicles.—*S. yunnanensis*, Franch. Allied to *S. villosa*. Shrub: lvs. elliptic-oblong to oblong-lanceolate, glaucescent beneath, glabrous, 1 $\frac{1}{2}$ -3 $\frac{1}{2}$ in. long: infl. slender, 3-6 in. long, puberulous: fls. pinkish, with upright-spreading lobes. S. W. China.

ALFRED REHDER.

SYZYGIIUM (from the Greek, *united*, referring to the calyptrate petals). *Myrtaceæ*. Trees and shrubs of the tropics of the Old World, variously defined and by some authors made a section of *Eugenia*: from *Eugenia* proper the group differs in the united petals, the calyx truncate or with a 4-5-lobed limb and no staminal disk: fls. small, in compact clusters: fr. small 1- or 2-seeded berries. As defined by Niedenzu, the genus has about 140 species. One or two names under this genus appear in the trade. For *S. jambolana*, see *Eugenia jambolana*, p. 1163, Vol. II.

operculatum, Niedz. (*S. nervosum*, DC. *Eugenia operculata*, Roxbg.). A large evergreen tree with 4-angled or nearly terete branches: lvs. opposite, broad-ovate or elliptic, rounded or somewhat acuminate at apex and narrowed at base, 3-8 in. long, dark green and glossy, the primary lateral nerves few and separated: fls. in 3's and collected into a more or less thyrsoid infl., greenish: berry $\frac{1}{2}$ in. or less diam., juicy, edible. Himalaya.—This name appears recently in Calif.: young plants described as having handsome foliage; said to be an acquisition.

L. H. B.

3764. *Syringa japonica*. ($\times \frac{1}{4}$)

T

TABEÛIA (Brazilian name). *Bignoniaceæ*. Ornamental trees grown chiefly for their showy flowers.

Evergreen: lvs. opposite, simple or digitate, entire or serrate; fls. in terminal panicles or racemes, rarely solitary; calyx irregularly splitting or unequally 3-5-lobed; corolla funnellform-campanulate; stamens included; disk annular or cupulate; ovary with the ovules in many series: caps. more or less compressed, usually elongated, glabrous or scaly.—About 90 species in Trop. and Sub-trop. Cent. and S. Amer. By Bureau and by Schumann, *Tabebuia* is limited to the 5 or 6 species with simple lvs., and the species with digitate lvs. are referred to *Tecoma*, while the *Tecoma* of this work is called *Stenolobium* by these authors. See, also, *Bignonia*.

The *tabebuias* are upright trees with large evergreen foliage simple or digitate and with large pink, white, or yellow flowers in terminal, usually few-flowered panicles or racemes or sometimes solitary. They are suited for cultivation in tropical or subtropical countries only and are sometimes grown in southern California and Florida. They grow luxuriantly in rich or well-manured soil and are easily propagated by cuttings and also by air-layering.

A. Lvs. simple.

leucóxyia, DC. (*Bignônia leucóxyia*, Vell. *B. pallida*, Lindl.). Fig. 3765. Evergreen tree or shrub: lvs. elliptic-oblong to obovate-oblong, obtuse or sometimes marginate at the apex, glabrous, dark green, with distinct pale midrib, 4-7 in. long; fls. in few-fl. terminal racemes; corolla funnel-shaped, about 2 in. long, with yellow tube and pale lilac limb. Brazil. B.R. 965.

AA. Lvs. digitate.

B. Fls. pink.

triphýlla, DC. (*Bignônia leucóxyilon*, Linn. *Tecoma leucóxyilon*, Mart.). Evergreen tree: lvs. long-petioled, digitate; lfts. 3-7, usually 5, stalked, oblong-lanceolate, entire, glabrous, 1-2½ in. long; fls. in usually few-fl., loose panicles or 1 or 2; corolla funnellform, with large, spreading limb, rosy pink or nearly white, suffused with pink, 2 in. long; calyx 2-lipped: caps. linear, 6-8 in. long. W. Indies, Guiana.

rôsea, DC. (*Tecoma rôsea*, Bertol.). Evergreen tree: lvs. digitate; lfts. 5, rarely 3, long-stalked, ovate to oblong, acuminate, entire; fls. in many-fl. terminal pan-

icles; corolla funnellform-campanulate, with short tube and large spreading lobes, rosy pink; calyx campanulate, obscurely 2-lobed, almost truncate. Guatemala.

BB. Fls. yellow.

chrysántha, Nichols. (*Tecoma chrysántha*, DC.). Evergreen tree: lvs. digitate; lfts. 5, ovate, acuminate, entire, tomentose, 4-7 in. long, long-stalked; fls. in terminal dense racemes, yellow, funnellform, 2 in. long. Caracas.

T. æsculifolia, Hemsl. (*Tecoma æsculifolia*, DC. *Bignonia æsculifolia*, Humb. & Bonpl.). Evergreen tree, about 20 ft. high; lvs. digitate, with 7 oblong-obovate lfts., pubescent above, tomentose beneath; fls. in terminal panicles, subcampanulate, orange-red, with yellow spots on the 3 lower lobes. Mex.—*T. Donnell-Smithii*, Rose. Known in Mex. as "Primavera" and said to be one of the most beautiful trees, sometimes 4 ft. diam., and the wood very valuable: fls. beautiful golden yellow, in great abundance, usually appearing before the palmately compound lvs.: lfts. 7, oblong to ovate, acuminate, rounded or truncate at base, serrate.—*T. Palmieri*, Rose. Tree, 18-25 ft., bearing paulownia-like fls.: lvs. opposite; lfts. 4, about 2-5 in. long, oblong, somewhat acuminate, obtuse at base; fls. white and purplish, with yellow spots, in close clusters at ends of naked branches; corolla 1½-2 in. long. Mex.—*T. pentaphylla*, Hemsl. (*Tecoma pentaphylla*, Juss.). Closely related to *T. triphylla*. Tree, to 60 ft.: lfts. usually 5, elliptic to oblong-obovate, obtuse or acutish; fls. rosy pink, larger. W. Indies, Cent. Amer., Venezuela. The plant intro. under this name by the Dept. of Agric. under No. 38649 is said to have orange-colored fls. and belongs probably to some other species.—*T. serratifolia*, Nichols. (*Tecoma serratifolia*, Don). Evergreen tree: lvs. digitate, with 4-5 oblong-ovate acuminate lfts. serrate at the apex, 3-5 in. long; fls. in terminal panicles, tubular-funnelform, yellow. W. Indies.—*T. spectabilis*, Nichols. (*Tecoma spectabilis*, Planch. & Lindl.). Evergreen tree: lvs. digitate, with 5 stalked ovate to oblong-ovate, crenately serrate lfts.: fls. in terminal panicles, orange-yellow, funnellform-campanulate. Colombia. F.S. 9:948.

ALFRED REHDER.

TABERNÆMONTÀNA (named for J. T. Tabernæmontanus of Heidelberg, physician and botanist; died 1590). *Apocynaceæ*. Evergreen usually glabrous trees or shrubs, grown in the warmhouse.

Leaves opposite, thin or leathery: cymes rather branched, terminal or dichotomously arranged: fls. white or yellowish, small or rather large; calyx usually short, deeply or to the middle 5-lobed or -parted; corolla salver-shaped, tube cylindrical, lobes twisted; disk various; ovary with 2 distinct carpels: berries or follicles 2, globose, oblong, ovoid or recurved-reniform, smooth or 3-ribbed.—About 160 species, widely distributed throughout the tropics. See *Gonioma* for distinctions from that genus.

The East Indian rosebay, *T. coronaria*, is one of the

3765. *Tabebuia leucoxyla*. (×½) C, winged seed.

best ornamental shrubs for subtropical gardens. This species and *T. Camassi*, referred in this work to *Gonioma*, flourish everywhere in Florida from Jacksonville southward. If they receive proper attention, tiny cuttings soon develop into dense, bushy plants 3 to 5 feet high, covered with deliciously scented flowers throughout the summer. Indeed the plants are so densely covered with buds and flowers that it is often difficult to find a sufficient supply of cuttings for propagation. *T. coronaria* has larger leaves than *T. Camassi* and the flowers are much like those of the double white oleander, while *T. Camassi* has solidier and smaller blossoms. Both do well under the same treatment. In order to enjoy the beauty of the East Indian rosebay to its fullest extent, it must be planted in rich, sandy soil, not too wet and not too dry, and in places fully exposed to the sun. Only very strong pot-grown plants should be set out in the garden. This should be done during the rainy season. Avoid breaking the ball in transplanting. It is useless to transplant in November, the time when most evergreens and other plants are most successfully set out. The plants at this season have not time to become established before the first sharp frost comes, and a weakened *tabernæmontana* is usually killed outright by even a slight frost. Just before Christmas all the plants of this nature (*bauhinias*, *cestrums*, *Poinciana regia*, *Tristania conferta*, *grevilleas*, *eucalypti*, and so on) are banked about 18 inches to 2 feet high with dry sand, and they always come through without much damage. In April or even earlier, the banking is taken away and the plants cut back to sound wood. The *tabernæmontanas* look best in groups by themselves or in front of other glossy leaved evergreens. (H. Nehrling.)

A. *Fls. white.*

coronaria, Willd. CRAPE JASMINE. NERO'S CROWN. A tender shrub, 6-8 ft. high: lvs. glossy green, oblong to oblanceolate: fls. white, fragrant, 1-2 in. across, in 1-8-fld. clusters in the forks of the branches; petals crimped on the margin, whence the common name. Cult. in India but native country unknown. Var. *flore-pleno*, with double, somewhat larger, very sweet-scented fls., seems to be far more common in cult. P.M. 16:354. B.M. 1865 (as *Nerium coronarium*).—Cult. in the more southern states and also in greenhouses. Also known as Adam's apple and East Indian rosebay.

AA. *Fls. yellow.*

grandiflora, Jacq. A small, tender shrub: lvs. oblong-ovate, sharply acuminate, 2-3 in. long, thick: fls. single, yellow, 1-2 in. long, in few-fld. clusters; corollalobes oval, obtuse, entire. Early fall. Carthage, Guiana. B.M. 5226.—Rarely cult. in the more southern parts of the U. S.

T. Camassi, Regel. See *Gonioma Kamassi*.—*T. dichotoma*, Roxbg. (*Cerbera dichotoma*, Lodd.). About 6 ft. high: lvs. oblong, acute at base, obtuse at apex, 2½-5 in. long; cymes terminal, dichotomously branched, many-fld.; fls. slightly odorous, 1 in. long. India. B.R. 27:53. L.B.C. 16:1516. H.W. 3, p. 259.—*T. grandifolia*, Hort., is listed in the American trade, presumably an error for *T. grandiflora*.

F. W. BARCLAY.

F. TRACY HUBBARD.†

TACAMAHAC: *Populus balsamifera*.

TÁCCA (Malayan name). Syn., *Atáccia*. *Taccææ*, a family allied to the *Dioscorea* tribes. Perennial herbs from a tuberous or creeping rhizome, adapted to the warmhouse.

Leaves radical, large, petioled, sometimes undivided and entire, sometimes variously lobed or dissected: fls. at the top of erect leafless scapes in dense umbels, lurid brown or greenish; perianth 6-lobed in 2 rows; stamens 6; ovary inferior, 1-celled: fr. globose, ovoid, turbinate or elongated, usually 3-cornered or 6-ribbed, berry-like and indehiscent, rarely finally 3-valved.—About 13 species in the tropics of both hemispheres. The fl.-cluster is subtended by a few, usually 4, leaf-like or

colored bracts, and intermixed with the fls. are more or less numerous, long and conspicuous, sterile, filiform pedicels, which usually droop below the fl.-cluster. *Taccææ* contains only one other genus, *Schizocapsa*.

A. *Lvs. much lobed.*

pinnatifida, Jack. Tender perennial herb, about 2 ft. high: rootstock globose, becoming 1 ft. through: lvs. large, usually 3-branched, the divisions pinnately cut or divided, the ultimate lobes sometimes irregular and unequal but usually ovate to lanceolate: fls. greenish, 8 lines across, many with the sterile pedicels purplish: berry nearly globular, 1 in. through. Afr., India, and Austral. L.B.C. 7:692. B.M. 7299, 7300.—According to Von Mueller's *Select Extra-tropical Plants*, the Fiji arrowroot is prepared from the tubers of this species. The plant thrives even on the sand-shores of tropical countries, and it is not unlikely that it will endure a temperate climate.

AA. *Lvs. not lobed.*

cristata, Jack (*Atáccia cristata*, Kunth). Rootstock a short conic caudex, marked with lf.-scars: lvs. 1-2 ft. long, oblong, acuminate, dark purplish green: scape longer than the lvs.: fls. dark purple, 1½ in. across, in a somewhat 1-sided umbel, with numerous pale sterile pedicels 8-10 in. long: involucre bracts 4, conspicuous, the 2 inner elliptical, narrowed to a petiole, the 2 outer revolute. Malaya. B.M. 4589. F.S. 9:860-861. Gn. 45, p. 415; 49, p. 423.—According to Gn. 45, p. 415, it requires good, rich, open soil, with ample drainage, plenty of water, and a stove temperature. In the winter season the plant should be kept in a state of partial rest.

Chantrièri, André. Plant stemless, on a fibrous, red-brown caudex: lvs. on petioles attaining a length of 28 in., which are dilated and imbricated at base, channelled and red-brown; blades oval, acute at apex, about 20 x 8-10½ in., brilliant shining green, not symmetrical at base: infl. red-brown, brilliant purple: spathe brilliant purple; fls. about 20, almost 2 in. long. Malaya. R.H. 1901, p. 541.—Resembling *T. cristata* but larger in its proportions and having more numerous long-stalked fls.

F. W. BARCLAY

F. TRACY HUBBARD.†

TACSÔNIA (from the Peruvian name of one of the species). *Passiflorææ*. From *Passiflora*, *Tacsonia* differs in having a long-tubular calyx, stamens and petals usually 5, the latter never wanting, corona of tubercles or very short threads, and in a short reflexed crown near the base of the fl.-tube. However, the line of demarcation between the two genera is often not well marked and Harms (Engler & Prantl's *Pflanzenfamilien*) unites *Tacsonia* with *Passiflora*. Masters (Trans. Linn. Soc. 27) accepts 25 species of true *Tacsonia*, relegating the intermediate forms largely to *Passiflora*. Other species have been discovered subsequently. The *Tacsonias* are all S. American, inhabiting the Andes. They are tendril-climbing shrubs or herbs, requiring the treatment given *passifloras*. *Tacsonias* are cult. freely in the open in Cent. and N. Calif. *T. manicata* (*Passiflora manicata*) is a common and striking red-fld. tall climber in S. Calif.

In this work, following Engler & Prantl and also Hooker, the *Tacsonias* are described under *Passiflora*.

TÆNÍDIA (Greek, making reference to the very small ribs of the fr.). *Umbelliferæ*. One species, a slender smooth glaucous perennial of E. Canada and U. S., *T. integerrima*, Drude, formerly known as *Pimpinella integerrima*, Gray, and *Zizia integerrima*, DC. It has little value to the horticulturist, although interesting to the collector of native plants for the hardy border. It is erect, 2-3 ft., slender, open-branched, with long-rayed umbels of small yellow fls. in spring and early summer: lvs. ternately 2-compound, the lflets oval to lanceolate, entire, nearly or quite obtuse.

TAGÈTES (*Tages*, an Etruscan god, or perhaps of other derivation). *Compósitæ*. MARIGOLD. American perennial and annual flower-garden herbs.

Leaves opposite or alternate, pinnately cut or rarely simply serrate: fl.-heads of various sizes, yellow or orange, marked in some species with red: strong-scented

plants with opposite or alternate mostly pinnately divided lvs. that bear oil-glands: involucre of united parts forming a cup or tube, naked at base: achene angled or flattened, the pappus of a few entire mostly unequal bristles or scales: rays pistillate; disk-fls. perfect.—Species about 20, from New Mex. and Ariz. to Argentina, mostly annuals. The popular annual species known as "African" and "French" marigolds have been derived respectively from *T. erecta* and *T. patula*, both of which are native to Mex. According to Sweet's *Hortus Britannicus*, these two species were intro. into cult. in 1596 and 1573.

For garden purposes *Tagetes* may be divided

into two groups, based upon habit of growth. *T. erecta* and *T. lucida* are of upright and somewhat open growth; while *T. patula* and *T. signata* are spreading and bushy, the lower branches lying close to the ground and often rooting. The French marigolds, *T. patula*, are valuable bedding plants. Good garden forms are of even height and bushy compact growth, with a mass of good foliage and well-colored flowers appearing continuously from June until frost. In raising plants, it is preferable to grow them in pots, as this practice seems to check the plants sufficiently to cause them to bloom at a small size and more plentifully during the early summer months than if they were raised with unlimited root room. They should be planted about 1 foot apart. This species also makes attractive specimens in small pots in a few weeks from seed. Mixed seed of the double sorts will give a large percentage of good double flowers, while the seed of special named double sorts is remarkably good. Some of the single forms are very finely colored. The African marigolds, *T. erecta*, are not well suited to bedding purposes, the growth being too open, but for the mixed border or shrubbery they are excellent late-blooming subjects. This species should be grown with plenty of root room, air, and rich soil from start to finish if the largest and most double flowers are desired. The African marigolds are very useful as cut-flowers except under circumstances where their odor is objectionable.

For pot marigold, see *Calendula*.

A. Fls. generally marked with red.

pátula, Linn. FRENCH MARIGOLD. Fig. 3766. A hardy annual, usually about 1 ft. high and much branched from near the base, forming a compact, bushy plant: lvs. darker green than in *T. erecta*, pinnately divided; lobes linear-lanceolate, serrate: fls. smaller than in *T. erecta* and borne on proportionately longer peduncles. Mex. B.M. 150; 3830 (as *T. corymbosa*).—Both the single and double forms are grown. The species is very variable as to the color-markings of the fls. which range from almost pure yellow to nearly pure red. A dwarf variety, *nàna*, Hort., is known. Gn. 63, p. 24; 73, p. 127.

AA. Fls. not marked with red.

B. Lvs. pinnately divided.

c. Rays numerous.

erecta, Linn. AFRICAN MARIGOLD. Fig. 3767. A hardy annual growing about 2 ft. high, erect, branched: lvs. pinnately divided, segms. lanceolate-serrate: fls. 2-4 times as large as in *T. patula* and of one solid color, the typical color, according to DeCandolle, being a lemon-yellow. Mex.—The rays are sometimes rather 2-lipped and in one of the garden forms they are quilled. The color ranges from a light sulfur-yellow to a deep orange, many of the light yellow shades being rare amongst fl. colors. This is the common marigold of old gardens in Amer. Foliage very strong-scented.

cc. Rays few, usually 5.

signàta, Bartl. An annual branching species: lvs. pinnately divided into usually 12 oblong, linear, sharply serrate segms., the lower teeth awned: rays 5, yellow, roundish-obovate. Mex. R.H. 1895, p. 505. Var. **pùmila**, Hort., a dwarf, bushy form, usually less than 1 ft. high, seems to be the only form in the trade. The fls. are bright yellow and small but numerous.—The species is suited for massing or for borders.

BB. Lvs. lanceolate, simply serrate.

lúcida, Cav. SWEET-SCENTED MARIGOLD. A tender perennial plant, entirely distinct from the foregoing annuals in the sessile, lanceolate lvs. and small, usually 2-3-rayed fls. in dense, terminal corymbs. The fls. have a much more agreeable odor than the other species cult. Mex. B.M. 740. R.H. 1895, p. 505.—Sometimes used as a substitute for tarragon, which see.

T. lácera is a species discovered about 1896 by T. S. Brandegee in Low. Calif. It makes a compact bush 4-5 ft. high, bearing a profusion of yellow fls. in winter. Small plants flower well in pots. See G.F. 9:67. —*T. Lémmouii*, Gray, also a shrubby nearly smooth plant about 2 ft. high, seems to be grown in Calif. It is distinctly woody but rather slender: lvs. all opposite, 3-7-foliate, the serrulate lfts. about 1 in. long: heads about 1 in. diam., showy. Ariz. G.C. III. 27:21.

F. W. BARCLAY.

TÀINIA (Greek, *band* or *fillet*, alluding to the shape of the lip). *Orchidacææ*. Terrestrial warmhouse orchids. Sterile st. from a many-sheathed rhizome finally thickened into a pseudobulb: lf. single, terminal, large, long-petioled: flowering scapes arising from the rhizome, tall, leafless, base few-sheathed, bearing a simple terminal raceme: fls. pedicellate, sparse, rather large or medium-

3766. Single French marigold.—*Tagetes patula*. (×¼)

3767. African marigold.—*Tagetes erecta*. (×½)

sized; sepals about the same length, narrow, acutish to acuminate; petals similar to the rear sepal or narrower; labellum affixed to the foot of the column, erect, gibbous at base, lateral lobes erect and parallel or clasping the column, the middle lobe spreading, short, broad; pollinia 8.—About 14 species, India, S. China, and Malaya.

Fuerstenbergiana, Schlecht. Tall: pseudobulbs ovoid, about 2 in. long, 1-ld.: lf. erect, petioled, lanceolate, about 2 ft. long: scape slender, erect, $2\frac{1}{2}$ -3 ft. tall, bearing a lax 10-15-fl. raceme: fls. about 2 in. across; sepals and petals oblong-ligulate; lip oblong, 3-lobed. Habitat(?).—Closely allied to *T. penangiana*.

penangiana, Hook. f. Not pseudobulbous: lf. 8-12 x $1\frac{1}{2}$ -2 in., about equaling the slender petiole: scape twice as long: sepals linear-lanceolate, $\frac{3}{4}$ in. long, acuminate; petals narrow, 5-7-nerved, spur shortly conical, obtuse; lip oblong, side lobes subacute, incurved, overlapping the orbicular, acuminate, crisped midlobe. Penang, Malayan Penins. F. TRACY HUBBARD.

TAINIÓPSIS (like *Tainia*). *Orchidaceæ*. Epiphytic plants, probably adapted to the coolhouse. Roots rather stout, with a short decumbent rhizome: pseudobulbs ovoid, slightly 4-angled, finally rugose, at apex 2-ld.: lvs. elliptic-lanceolate, acuminate, narrowed to the petiole, lightly plicate, 1 ft. or more long: scape lateral from near the base of the pseudobulb, erect, slender, more or less exceeding the lvs.: infl. simple or slightly branched, laxly several- or many-flid.: sepals ringent, ligulate, rather obtuse, minutely puberulent outside, glabrous inside, lateral recurved, falcate, base broadened; petals obliquely linear, obtuse, recurved, glabrous, as long as the sepals; labellum curved, mobile, lanceolate-tongue-shaped, apex hastately dilatate with the margins incurved; column medium-sized, broadened toward the apex; pollinia 8. One species, Khasia Mts. and Burma, *T. barbata*, Schlecht. O. 1915:11.

F. TRACY HUBBARD.

TALAUMA (S. American name). *Magnoliaceæ*. Evergreen trees, grown occasionally in the warmhouse. Lvs., infl., and seeds as in *Magnolia*: sepals 3; petals 6 to many, imbricate in 2 rows; stamens numerous; carpels numerous, capitate or spicate, 2-ovuled.—About 30 species in the tropics of E. Asia, S. Amer., and Japan. *Talauma* is closely allied to *Magnolia*, but the carpels are indehiscent and deciduous, while those of *Magnolia* dehisce dorsally and are persistent.

Hodgsonii, Hook. & Thom. Tender evergreen tree, 50-60 ft. high, producing lvs. and fls. at the same time: lvs. 8-20 x 4-9 in., obovate-oblong, cuspidate or obtuse, leathery, glabrous: fls. cup-shaped, fully 6 in. across and 4 in. deep, solitary, terminal; sepals 3-5, purple outside; petals about 6: fr. 4-6 in. long. Himalayas. B.M. 7392.—The fls. have a spicy odor, hard thick fleshy texture, and the glaucous purplish blue of the sepals contrasts well with the ivory-white of the petals. Hooker ranks this species second in beauty only to *Magnolia Campbellii* (p. 1969, Vol. IV). *T. Hodgsonii* grows at an elevation of 5,000-6,000 ft. This fine tree has been flowered at Kew and perhaps elsewhere in Eu., but never in Amer., so far as is known. Many times seeds were received at Kew from India, but they never germinated, the reason being the rapid decay of the albumen, involving that of the embryo. The trees now cult. in Eu. have been derived from young plants sent from India in Wardian cases at considerable expense and risk.

WILHELM MILLER.

TALINUM (possibly a native name in Senegal). *Portulacaceæ*. Fleshy herbs, sometimes becoming woody at the base with age, occasionally cult. in the warmhouse. Lvs. alternate or rather opposite, flat: fls. small, in terminal cymes, racemes, or panicles, rarely solitary, axillary, or lateral; sepals 2; petals 5, hypog-

ynous, ephemeral; stamens 5 to many; ovary many-ovuled: caps. globose or ovoid, chartaceous, 3-valved.—About 15 species, widely scattered in the warmer regions.

The variety of *T. patens* is a handsome greenhouse shrub, with foliage marked white and sometimes also pink. The young stems are pink and succulent, but they become woody with age. The plant is allied to portulaca and will endure much heat and drought, but is very impatient of overwatering and lack of drainage. The plants bloom freely, the flowers being small, light pink, and followed by small yellow capsules filled with an indefinite number of little brown seeds. Some prefer to retain the sprays of blossom, but to make the best show of foliage the flower-shoots should be cut off as soon as they appear. *Talinum* is a satisfactory house-plant. It should be placed in a window with a northern exposure or in some other shady position. *Talinum* may also be planted out during the summer. (W. C. Steele.)

patens, Willd. Erect subshrub: st. almost simple, 1-2 ft. high, leafy to the middle, where the panicle begins: lvs. mostly opposite, oval, abruptly tapering at the base: panicle terminal, long, leafless, bearing dichotomous cymes: fls. carmine; petals 3 lines long; stamens about 15-20. W. Indies and east coast of S. Amer. to Buenos Ayres. Var. **variegatum**, Hort. ("*Tolimum variegatum*," Hort. *Basella variegata*, Hort.), is probably the plant described as sweet Malabar vine in Vol. I, page 455, of this work.

triangulare, Willd. Lvs. alternate, obovate-lanceolate: cymes corymbiferous: pedicels 3-cornered (in *T. patens* they are filiform): fls. red or white. W. Indies, Brazil, Peru. Var. **crassifolium**, Hort. (*T. crassifolium*, Hort.), is said to be taller and more branched: lvs. larger, often emarginate and mucronate.

F. TRACY HUBBARD.†

TAMARACK: *Larix*.

TAMARÍNDUS (from the Arabic *tamar-Hindi*, meaning "Indian date"). *Leguminosæ*. A tropical genus containing but one species, the well-known tamarind. It is considered to be indigenous to tropical Africa (the upper Nile region) and possibly southern Asia as well. It has long been cultivated throughout the tropics of both hemispheres, being grown both as an ornamental and for its acid fruits, which have many uses. The tamarind became known in Europe during the Middle Ages, doubtless through the Arabians. Until correctly described by Garcia d'Orta (1563) it was supposed by Europeans to be produced by an Indian palm (*Dymock*).

Leaves alternate, equally pinnate, the lfts. small, indefinite in number; stipules minute, caducous: fls. irregular, produced in racemes at the ends of the branches; bracts and bracteoles ovate-oblong, colored, caducous; calyx-tube turbinate, narrow, the segms. 4, imbricate, membranaceous, colored; 3 superior petals imbricate, yellowish, veined with red, 2 inferior reduced to bristles hidden at the base of the staminal tube; fertile stamens 3, connate in a sheath, opening above with short, free filaments, anthers oblong, longitudinally dehiscent; ovary many-ovuled, with a stalk adnate to the calyx-tube, the style filiform, stigma terminal, subcapitate: fr. an oblong or linear, compressed, indehiscent pod, with a thick, crustaceous epicarp, pulpy mesocarp, and coriaceous endocarp septate between the obovate-orbicular, compressed seeds; embryo exalbuminous. The genus is distinguished from *Schotia*, the only ally which seems to be cult. in Amer., by its floral characters.

indica, Linn. **TAMARIND**. **TAMARINDO**. Fig. 3768. A large tree, attaining to 80 ft. in height when grown on deep soils, with a trunk 25 ft. in circum.: bark brownish gray, somewhat shaggy: lvs. abruptly pin-

nate; lfts. 20-40, opposite, oblong, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, glabrescent, soft, pale green, obtuse: fls. few together in lax racemes, individually about 1 in. broad, pale yellow, the petals veined red; calyx-teeth lanceolate, the lowest 2 connate: pod 3-8 in. long, $\frac{3}{4}$ -1 in. broad, cinnamon-brown, with a brittle epicarp and brown pulp inclosing 1-12 seeds. Flowers in April and May in the northern hemisphere, ripening fr. in late autumn and winter. B.M. 4563 (as *T. officinalis*). J.F. 2:133.—The tamarind is a magnificent evergreen tree, extensively cult. in nearly all tropical countries. It succeeds in S. Fla., and has been grown as far north as Manatee, where a large specimen was killed by the freeze of 1884. It is not sufficiently hardy to be grown in Calif., failure having attended all past efforts to cult. it in that state, so far as known. It delights in a deep alluvial soil and abun-

3768. The tamarind, *Tamarindus indica*.—Short-podded or West India form. ($\times \frac{1}{2}$)

dant rainfall, the largest specimens being found in tropical regions where the soil is rich and deep. On the shallow soils of S. E. Fla. it does not attain to great size. When small it is very susceptible to frost, but when mature it will probably withstand temperatures as low as 28-30° F. without injury.

The plump slightly curved pod has a thin brittle shell. It contains a soft brownish pulp transversed by a few strong branched fibers; the large flattened glossy seeds, varying from one to twelve in number, are surrounded by a thin tough membrane. The pulp contains sugar together with acetic, tartaric and citric acids, the acids being combined, for the most part, with potash. In East Indian tamarinds, according to Dymock (Pharm. Ind. pt. II, 532-36) citric acid is present in a small quantity, about 4 per cent, while there is about 9 per cent of tartaric. The pulp is widely used in the Orient as an ingredient in chutnies and curries, and for pickling fish. In medicine, it is valued by the Hindus as

a refrigerant, digestive, carminative, laxative, and antiscorbutic, for which latter purpose it is sometimes used in place of lime juice. With the addition of sugar and water, it makes a cooling drink or refresco, especially well known in Latin America. For the preparation of this drink, a sirup is often made from the pulp which can be bottled and used as desired. In some countries tamarinds are an important article of export. In Jamaica the fruit is prepared for shipment by stripping it of its outer shell, and then packing it in casks, with alternate layers of coarse sugar. When the cask is nearly full, boiling sirup is poured over all, after which the cask is headed up. In the Orient, the pulp, containing the seeds, is pressed into large cakes, which are packed for shipment in sacks made from palm leaves. This product is a familiar sight in the bazaars. It seems to be greatly esteemed as an article of diet by the Indians, as also by the Arabs, large quantities being shipped to Arabia from India.

According to Watt, the natives of India have an aversion to sleeping under the shade of the tree because of the supposed acid exhalation from the leaves. Pittier states, however, that he has slept under a tamarind tree for weeks without suffering the least inconvenience. Gamble writes that the leaves corrode the cloth of tents pitched in the shade of the tree. This happens, he says, in wet weather; the leaves fall on the tents, and within a day or two the cloth is decomposed in holes.

The tree is easily propagated by means of seeds, which is the only method commonly used. Seeds can be transported without difficulty, as they retain their viability for a considerable length of time if kept dry. They are best germinated by planting them $\frac{1}{2}$ inch deep in light, sandy loam. The young plants are rather delicate and must be handled carefully to prevent damping-off. In India, the yield of a mature tree is said to be about 350 pounds of fruit per annum. Little is known of the insect pests which attack the tree; Maxwell-Lefroy mentions two, *Caryoborus gonagra*, a large gray-brown chrysomelid beetle found in tamarind seeds, and *Charaxes fabius*, a large black yellow-spotted butterfly whose larvæ feed on the leaves. Both these insects occur in India.

Firminger mentions three varieties of tamarind grown in India, but does not know whether they can be depended on to come true from seed. Masters, in the "Treasury of Botany," states that the East Indian variety has long pods, with six to twelve seeds, while the West Indian variety has shorter pods, containing one to four seeds. Seedlings undoubtedly show considerable variation in the size and quality of their fruit, which accounts for the different varieties which have been noted by many writers. Firminger recommends that seedlings which produce unusually choice fruit be propagated by gootee, or stem-layering, a method which is described under Litchi. More recently (1913) Wester has reported that the tree can be shield-budded successfully the method being similar to that used with avocado.

F. W. POPENOE.

TAMARISK: *Tamarix*.

TĀMARIX (ancient Latin name). *Tamaricaceæ*. **TAMARISK.** Ornamental woody plants, grown chiefly for their showy panicles or racemes of pink or whitish flowers; and also for their very fine graceful foliage.

Deciduous shrubs or trees: lvs. alternate, sessile, often sheathing, small, and scale-like: fls. small, short-pedicelled or sessile, in rather dense racemes, usually collected into terminal panicles; sepals and petals 4-5; stamens usually 4-5, rarely 8-12, sometimes slightly connate at the base; ovary 1-celled, surrounded at the base by a more or less deeply 5- or 10-lobed disk; styles 2-5, clavate or short and thick: fr. a caps., dehiscent into 3-5 valves; seeds many, minute, with a tuft of hairs at the apex.—About 75 species from the Medit. region to

E. India and Japan. Several species have medicinal properties and yield dye-stuffs. The punctures of an insect, *Coccus manniparus*, cause *T. mannifera* to produce "manna."

The tamarisks are very graceful shrubs or small trees with slender branches clothed with minute scale-like appressed leaves, and with usually light pink small flowers in large and loose terminal panicles or in numerous lateral racemes, followed by small capsular fruits. None of the species is quite hardy North, but *T. pentandra*, *T. odessana*, *T. gallica*, and *T. parviflora* are fairly hardy as far north as Massachusetts. Several of the species bloom late in summer and are a welcome addition to the autumn-flowering shrubs. As they are inhabitants of warmer arid regions, they are adapted for dry-land conditions, and they also grow well in saline and alkaline soil. They are excellent for seaside planting and thrive in the very spray of the salt water. Propagation is by seeds, which are very fine and should be only slightly covered, or usually by cuttings of ripened wood in the open ground or by greenwood cuttings under glass.

KEY TO THE SPECIES.

- A. Fls. 4-merous: racemes lateral on last year's branches.
 - B. Petals spreading, persistent; styles usually 5. 1. *parviflora*
 - BB. Petals erect, deciduous; styles usually 4. 2. *tetrandra*
- AA. Fls. 5-merous.
 - B. Racemes lateral on last year's branches. 3. *juniperina*
 - BB. Racemes forming large terminal panicles, rarely lateral on the current year's branchlets.
 - C. Lvs. glabrous.
 - D. Petals persistent.
 - E. Bracts ovate-lanceolate. 4. *pentandra*
 - EE. Bracts subulate.
 - F. Infl. nodding: tree with spreading branches. 5. *chinensis*
 - FF. Infl. upright: erect shrub. 6. *odessana*
 - DD. Petals deciduous. 7. *gallica*
 - CC. Lvs. finely pubescent. 8. *hispida*

1. *parviflora*, DC. (*T. tetrandra* var. *parviflora*, Boiss. & Kotschy). Fig. 3769. Shrub or small tree, 15 ft. high, with reddish brown bark and slender spreading branches: lvs. ovate, acuminate, semi-amplexicaul, scarious at the apex when older: fls. pink, very short-pedicelled, in slender racemes about 1 in. long along last year's branches; petals spreading, persistent; calyx very small, sometimes only 3-parted; styles usually 3, much shorter than ovary. April, May. S. Eu. F.S. 9:898. R.H. 1855:401. Gn. 61, p. 273; 71, p. 358. —Often confounded with the *T. tetrandra*, also with *T. africana* and *T. gallica* and cult. under those names. *T. tetrandra* var. *purpurea* probably belongs here.

2. *tetrandra*, Pall. Shrub or small tree, attaining 12 ft., with almost black bark: lvs. ovate-lanceolate, somewhat narrowed at the base, with diaphanous margin: fls. light pink or almost white, in racemes 1–2 in. long along last year's branches; disk purple, deeply 4-lobed; styles usually 4, about as long as ovary. April, May. S. E. Eu., W. Asia.—Doubtful whether in cult. in this country; all plants seen under this name by the writer belong to the preceding species.

3. *juniperina*, Bunge (*T. japonica* and *T. plumosa*, Hort.). Shrub or small tree, attaining 15 ft., with

slender spreading branches: lvs. green, oblong-lanceolate, acuminate, scarious at the apex: fls. pinkish, in lateral racemes $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long on last year's branches; pedicels slender, shorter than calyx; sepals ovate-lanceolate, little shorter than the persistent petals; disk 5-lobed, with emarginate lobes. Japan, N. China. S.Z. 1:71 (as *T. chinensis*.)

4. *pentandra*, Pall. (*T. Pallasii*, Desv. *T. hispida æstivalis*, Hort.). Shrub or small tree with usually purple branches: lvs. lanceolate to ovate, acute, glaucous or pale green: fls. pink, in large panicles, the racemes dense, 1–2 in. long; bracts ovate-lanceolate, acute or acuminate, as long or slightly longer than pedicels; petals broadly elliptic-oblong, connivent; disk 5-lobed, with emarginate lobes; styles 3, with obovate, connivent stigmas. Aug., Sept. S. E. Eu. to Cent. Asia. B.M. 8138. Gn. 77, p. 494. Gn. W. 25:121.—*T. amurensis*, Hort., is a form of this variable species. F.E. 20:344, pl. 105. Also *T. caspica* probably belongs here.

3769. *Tamarix parviflora*. ($\times \frac{1}{2}$)

keeled, semi-amplexicaul, with scarious margin: fls. white or pinkish, globose in bud, almost sessile, in slender, paniced racemes; petals deciduous; filaments somewhat dilated at the base, inserted between the rounded lobes of the 10-lobed disk; styles 3. May–July. W. Eu., Medit. region to Himalayas; naturalized in S. Texas and N. Mex. Gn. 34, p. 329. Var. *indica*, Ehrenb. (*T. indica*, Willd.). With slender, upright branches: lvs. dull green: racemes longer and slenderer: fls. pink, disk obscurely and minutely 10-lobed. Himalayas. Var. *marbonnensis*, Ehrenb. Racemes short, almost sessile, lateral on the current year's branches. S. W. Eu. Var. *élegans*, Schelle (*T. elegans*, Hort.), is a garden form of slenderer habit and with brighter green foliage; blooms somewhat later.

8. *hispida*, Willd. (*T. kashgarica*, Hort.). Shrub, with slender upright branches: lvs. bluish green, cordate and subauriculate at the base, acuminate, somewhat spreading, finely pubescent: fls. pink, almost sessile, in dense racemes 2–3 in. long, disposed in terminal panicles;

5. *chinensis*, Lour. Shrub or small tree, attaining 15 ft., with slender spreading, often drooping branches: lvs. bluish green, lanceolate, acuminate, keeled: fls. pink, in large and loose usually nodding panicles, pedicels as long as calyx; sepals ovate, much shorter than the persistent petals; disk deeply 10-lobed. July–Sept. China.

6. *odessana*, Stev. Shrub, 4–6 ft. high, with upright, slender branches: lvs. lanceolate, subulate, decurrent: fls. pink; racemes slender, about 1 in. long, on short, naked peduncles, spreading and disposed in ample loose panicles; pedicels about as long as calyx; petals slightly spreading; disk 5-lobed, with rounded lobes. July–Sept. Caspian region.

7. *gallica*, Linn. (*T. arborea*, Sieber, not Ehrenb. *T. canariensis*, Willd.). Shrub, or small tree with slender spreading branches: lvs. dull to bluish green, closely imbricated, rhombic-ovate, acute or acuminate,

petals deciduous, much longer than sepals; disk 5-lobed. Aug., Sept., R.H. 1894:352.

T. africana, Poir. Allied to *T. juniperina*. Racemes 2-3 in. long; fls. very short-pedicelled; styles slender. Medit. region. Apparently not in cult.; the plant offered in trade under this name is usually *T. parviflora*.—*T. algerica* or *T. algeriensis*, Hort., is probably *T. gallica*; no species has been described under these names. The Algerian species are: *T. gallica*, Linn., *T. brachystylis*, Gay, *T. boumopea*, Gay, *T. africana*, Poir., *T. Balansea*, Gay, *T. rubella*, Battand., *T. parviculata*, Gay, and *T. articulata*, Vahl.—*T. anglica*, Webb. Allied to *T. gallica*. Shrub, to 10 ft.: lvs. bluish green, somewhat constricted at the base; fls. ovate in bud; filaments filiform at the base, attached to the acute lobes of the 5-angled disk. W. Eu. S.E.B. 2:261.—*T. articulata*, Vahl. Tree, attaining 30 ft., with slender, jointed branches: lvs. glaucous, minute, sheathing; fls. 5-merous, pink, sessile, in terminal panicles. W. Asia. Not hardy N.—*T. dahurica*, Willd.=*Myricaria dahurica*.—*T. germanica*, Linn.=*Myricaria germanica*.—*T. rubella*, Battand. Allied to *T. parviflora*. Tree or shrub with red erect branches: lvs. minute, imbricate; bracts ovate, acute, almost as long as calyx; calyx-segms. 4; petals 4, rose; stamens 4, with long filaments and dark purple anthers. Algeria.

ALFRED REHDER.

TAMONEA (native name). *Melastomaceæ*. This name was revived to cover the names *Cyanophyllum*, *Miconia*, and others (Krasser, in Engler & Prantl, *Die Natürlichen Pflanzenfamilien*, III. 7. 1898), but later (Nachtr. 1, p. 267) the name *Miconia* was restored. *Miconia* is also retained in the list of "nomina conservanda" of the International (Vienna) Congress. Our cross-reference from *Cyanophyllum* to *Tamonea*, therefore (Vol. II, p. 930), should be to *Miconia*. There is apparently only one plant commonly known in cult. as *Cyanophyllum*, and this is accounted for as *Miconia magnifica* on p. 2047, Vol. IV; and others are there described. Under these dispositions, therefore, the name *Cyanophyllum* is dropped.

TAMUS (the old Latin name used by Pliny). Also spelled *Tamnus*. *Dioscoreaceæ*. Herbaceous perennials from a tuberous root: st. annual, twining; lvs. alternate, cordate, entire or 3-lobed; infl. axillary racemes; male often elongated, lax, with the fls. solitary along the rachis or disposed in lax few-fl. racemelets or cymules; female very short, few-fl., sometimes reduced to a sessile fascicle; fls. dioecious; male perianth urn-shaped-campanulate, deeply 5-cleft; stamens 6; female perianth-segms. 6, small, narrow, distinct; staminodes minute or none; ovary 3-celled: berry subglobose, succulent, indehiscent. About 2 species, 1 from Canary Isls., the other from Eu., N. Afr., and Temp. Asia. *T. communis*, Linn. BLACK BRYONY. Rootstock ovoid, black, fleshy: st. very long, twining, branched: lvs. 2-3 in. long, ovate-cordate, acuminate, obscurely laterally lobed: fls. yellowish green, small: berry red. May, June. Eu., N. Afr., and Temp. Asia.

TANACETUM (name of doubtful derivation). *Compositæ*. Annual or perennial herbs which are odorous: lvs. alternate, variously cut; heads of small to medium-sized yellow fls. disposed in corymbs, or rarely solitary, heterogamous, disk-shaped; female fls. with 3-5-toothed, tubular corollas: achenes 5-ribbed or 3-5-angular, with a broad truncate summit, bearing a coroniform pappus or none.—Thirty-five species scattered about the northern hemisphere, of which about 7 are native to N. Amer. For cult., see *Tansy*.

vulgare, Linn. (*Chrysanthemum vulgare*, Bernh.). **TANSY**. Fig. 3770. St. robust, erect, 2-3 ft., leafy to the summit: lvs. pinnately divided into linear-lanceolate segms. which are serrate or pinnately cut; fl-heads $\frac{3}{4}$ - $\frac{1}{2}$ in. across, numerous, in a dense flat-topped cyme. July-Sept. Eu. Adventive in the U. S. Var. *crispum*, DC., has the lvs. more cut and crisped.

T. adenanthum, Diels. Plant densely tufted, 6-12 in. high: lvs. finely divided, clothed with white silky hairs; fl-heads about $\frac{1}{4}$ in. across. W. China.—*T. quercifolium*, W. W. Smith. Lower lvs. 4-6 in. long; fl-heads containing about 20 yellow florets. Yunnan.

F. W. BARCLAY.

TANAKÆA (named in honor of M. Tanaka). *Saxifragaceæ*. Herb probably hardy and perennial: plant dioecious, perhaps sometimes monœcious, stoloniferous; stolons slender, leafy and rooting: lvs. basal, long-petioled, thick or somewhat fleshy, finally leathery, including the petioles 4-8 in. long; blade oblong-lanceolate or ovate-lanceolate, rounded or somewhat cordate at base, acute, doubly serrate: scapes very slender, branched, pyramidal, 6-8 in. high: fls. very small, greenish white, shortly pedicelled, solitary in the axils of the bracts; sepals 5, almost free, oblong-lanceolate; petals none; stamens 10, alternate ones shorter; ovary glabrous, almost entirely free, 2-celled.—One species, Japan, *T. radicans*, Franch. & Sav. B.M. 7943. G. 35:373; 36:515.

TANGELO (from tangerine and pummelo; by syn-copation: tange[rine] [pummelo]). A new group of citrous fruits originated in 1897 by the writer by crossing the Dancy tangerine with the Bowen grapefruit.

3770. Tansy.—*Tanacetum vulgare*. ($\times \frac{1}{2}$)

The resulting hybrid, named Sampson tangelo by H. J. Webber and the writer (United States Department of Agriculture Yearbook, 1904) does not closely resemble either parent in its fruit characters, being a slightly pear-shaped thin-skinned smooth and shining fruit of medium to large size, pale orange in color, and with a rather acid sprightly flavored very soft and juicy orange-colored pulp. It ripens very late, several months after it begins to color, and sometimes becomes partly dry before complete maturity. When properly grown it is a delicious fruit. It is being grown commercially on a small scale, but its delicate skin and liability to dry out before fully ripe probably will preclude its culture except by experts for a special market.

The Thornton is another tangelo, a hybrid of tangerine with a Florida grapefruit. It is a rough thick-skinned round fruit with very pale orange-colored juice and sprightly flavored pulp. It ripens earlier than the Sampson tangelo and is less acid. It is very like a tender good-flavored orange in character. It is beginning to be grown commercially on a small scale.

The success of the first two tangels produced by artificial hybridization has led to the creation of hun-

dreds of additional hybrids between all the mandarin types of orange (*Citrus nobilis*) such as the tangerine, willow-leaf mandarin, King, Satsuma, and the like, and the better sorts of grapefruit and pummelo (*Citrus grandis*). These fruits in general resemble round oranges (*Citrus sinensis*) more than either of their parents and are exceedingly variable, sister fruits from seeds of a single cross-pollinated fruit often being very unlike. Among the tangelos there are some of much promise because of their superior flavor and juiciness.

The spread of citrus canker (a bacterial disease caused by *Pseudomonas citri*) to many of the hot moist orange-growing regions of the world makes it desirable to breed new types of tangelos by hybridizing the canker-resistant mandarin oranges with canker-resistant pummelos such as can be found in the Orient. Such tangelos, if canker-resistant, could perhaps be grown in place of the more susceptible round oranges, just as limequats can be grown in place of the common lime, which is very susceptible to canker.

WALTER T. SWINGLE.

TANGERINE: *Orange* and *Citrus*.

TANSY (*Tanacetum vulgare*, Linn.). A coarse-growing herbaceous perennial naturalized from middle Europe, and a familiar occupant of old gardens, waste places, and roadsides. Its common name is said to be derived from *athanasia*, immortality, an idea suggested to the ancient Greeks by the characteristic permanent possession it takes of the soil. Its annual upright usually unbranched stems, which rise about 3 feet from the perennial root, bear greatly divided deeply cut compound bitter aromatic leaves and rather dense corymbs of numerous small yellow flower-heads which appear in mid-summer. The seed, which is small, is marked by five rather prominent grayish ribs and retains its vitality for about two years. Formerly its leaves were in great favor as a seasoning for various culinary preparations, especially puddings and omelettes, uses now almost obsolete. By the medical profession, its tonic and stimulant properties and its efficacy in hysterical and dropsical disorders are still recognized, although other medicines are

3771. Small-leaved form of dandelion.

3772. Large-leaved form of dandelion.

3773. Cut-leaved form of dandelion.

more popular. In domestic practice it played an early rôle as an antelmintic and stomachic and is still somewhat popular as a local agent to relieve the pain of muscular rheumatism, bruises, and chronic ulcers. The wild plants usually satisfy all demands, but when no wild supply is at hand seed may be used to start the half-dozen specimens that a family should need. Easily started, readily transplanted or divided, tansy requires no special care in cultivation except to keep it clear of weeds and to prevent its spreading and thus becoming troublesome. It will thrive in almost all soils and situations that are not too wet. For botanical account, see *Tanacetum*.

M. G. KAINS.

TAPEINÔTES (from the Greek, referring to its low stature). *Gesneriaceæ*. Under this generic name, one species is listed abroad, *T. Carolinæ*, Wawra. The genus is now included in *Sinningia* and the current name is *S. Carolinæ*, Benth. & Hook. (*S. barbata*, Nichols.). It is a Brazilian plant, adapted to the greenhouse: decumbent or ascending, with oblong to lanceolate crenate-serrate lvs. 1 ft. or less long and red beneath; fls. white, red-marked inside, with a contracted and hairy throat and tube swollen at base. B.M. 5623, which represents a striking plant with lvs. brilliant red-purple beneath and curved hairy deflexed white corollas 1½ in. long; described as a small under-shrub.

TAPIOCA: *Manihot*.

TAPIRIRA (from a native name in Guiana). Also spelled *Tapiria*. *Anacardiaceæ*. A name of disputed application. The plant likely to interest horticulturists in this relationship is *Cyrtocarpa procera*, from Mex., described on p. 945, Vol. II. Of *Tapirira* itself, distinguished by 4-5 styles, those in the pistillate fls. short, none is probably regularly in cult. As formerly defined, the species are S. American, with a few in Afr. and Asia, 8 or 10 in number. Later authors restrict the genus to S. Amer., mostly to Brazil. Under any definition, the genus is probably adapted to cult. only on our southernmost borders.

TAPÍSCIA (anagram of *Pistacia*, to which it bears a strong resemblance, though not closely related).

Staphyleaceæ. An ornamental deciduous tree from China with large alternate odd-pinnate lvs., deciduous stipules and with small yellow fragrant fls. in axillary panicles: calyx tubular-campanulate, 5-lobed; petals 5, spatulate-obovate, little longer than the calyx; stamens 5, exserted; style slender, longer than stamens; ovary superior: fr. a 1-seeded ovoid drupe. It is as yet little known in cult., but probably can be grown successfully in the S. only; it may be recommended chiefly for its bold pinnate foliage and the honey-scented fls. Prop. can probably be effected by cuttings besides by intro. seeds. *T. sinensis*, Oliver. Small tree, to 30 ft., occasionally to 90 ft.: lfts. 5-7, ovate to ovate-oblong, acuminate, cordate at the base, serrulate, glaucescent and nearly glabrous beneath, 3-5 in. long: panicles broad, 2-3 in. long: fls. $\frac{1}{2}$ in. long, yellow, fragrant: fr. ovoid, black, $\frac{1}{2}$ in. long. June, July. Cent. and W. China. H.I. 20:1928. ALFRED REHDER.

TARÁXACUM (name probably associated with supposed medicinal properties). *Leontodon* of some authors. *Compósitæ*. DANDELION. Low nearly or quite stemless herbs of cold and temperate regions, mostly of the northern hemisphere. Distinguished by having large many-fld. ligulate yellow heads solitary on naked and hollow scapes; involucre with one inner series of

erect narrow bracts and outer calyx-like spreading sometimes reflexed bracts; pappus simple and capillary, borne on a slender beak terminating a fusiform elongated angled achene: fls. opening in sunshine. The plants are exceedingly variable and there are consequently great differences of opinion as to the number of species. Bentham & Hooker would reduce them to about 6, and others would retain 25 or more. The common dandelion is *T. officinale*, Weber, known also as *T. Dens-leonis*, Desf. It varies immensely in stature and form of lvs., as shown in Figs. 3771-3774. For history, see Sturtevant, Proc. 6th Meeting Soc. Prom. Agr. Sci., and Amer. Nat., Jan., 1886. For an account of the red-seeded dandelion, *T. erythrospermum*, Andr., see Fernald, Bot. Gaz., July, 1895:323. From the common dandelion it differs in having smaller sulfur-yellow heads, smaller and very deeply cut lvs., outer involucre scales not reflexed and somewhat glaucous: achenes red or red-brown and shorter beaked: pappus dirty white. It is known to occur in New England, N. Y., Pa. and W.; probably naturalized from Eu. For the cultural directions, see *Dandelion*, Vol. II.

L. H. B.

TARE, TARES. To the modern English farmer the word "tare" means the common vetch, *Vicia sativa*, although tare is also applied loosely to other species of *Vicia* and *Lathyrus*, particularly *Vicia hirsuta*. The celebrated passage in Matthew xiii, 25, "His enemy came and sowed tares among the wheat," refers probably to the darnel, *Lolium temulentum*. The original Greek word in Matthew is *Zizania*, a name which in botany refers to the wild rice. Darnel belongs to the grass family and its seeds were long thought to stupefy those who ate them unwittingly. The supposed narcotic property in the fruit is said to be due to the presence of a fungus.

TARO. A group of tuberous-rooted edible aroids, of the genus *Colocasia*, scattered throughout the tropics and subtropics of the world; cultivated also in many warm regions of the temperate zones, as Egypt, Syria, China, Japan, and New Zealand, and latterly in the southern United States.

The taro has been cultivated from very early times and the Egyptian variety, under the name "colocasia," is mentioned by Pliny as being of great importance in Egypt at that time. The culture of it was said to have been already introduced into Italy. The Egyptian variety, now called golqas, is *Colocasia antiquorum* (Arum *Colocasia*), Fig. 3775, a quite different plant from that of the varieties most commonly grown in southeastern Asia and the islands of the Pacific. The golqas is of very inferior quality and is said to be eaten in Egypt only by the laboring classes.

The botany of the taros of the Pacific regions is in an unsatisfactory state, owing largely to the infrequency with which many varieties flower, but most of them evidently belong to *Colocasia esculenta* (by some considered to be a variety of *C. antiquorum* and so treated in Vol. II, page 830). See Fig. 3776.

The culture of taro has probably reached its highest development in the Hawaiian Islands and it is largely through its extensive use there that the plant has become so widely known among travelers and others. The large number of varieties despite the fact that the plants seldom, if ever, set seed, testifies to the antiquity of the culture of this type of taro. MacCaughey and Emerson, in the Hawaiian Forester and Agriculturist

3774. Variation in foliage of the common dandelion. (All leaves drawn to the same scale.)

(vols. 10, 11, 1913-1914), record a list of 262 named varieties of taro, or "kalo," which are said to have been grown on the islands. But few of these are of commercial importance, and many are no doubt lost.

In Hawaii, taro is eaten mostly in the form of poi, a sticky paste made by steaming or boiling the taro, then peeling and "pounding" or grinding it with the addition of a little water. It is usually allowed to ferment for a day or two before being eaten, and is considered to be a very easily digested, wholesome, and nutritious food. The organisms involved in the fermenting process are probably not always the same, but they appear to include a yeast and one or more bacteria. Fermented or sour poi is not alcoholic, but acid. Poi frequently constitutes an important part of the diet of invalids. By others it is usually eaten with meat, especially fish. Taro is also eaten boiled, or parboiled and baked, and in many other ways like the potato. Most varieties are acrid in the raw state, however, and these often require longer cooking in order to destroy this property. When properly cooked and served, the better varieties of taro are highly palatable and constitute a most valuable food. The young leaves, before they open, are prized as greens and are called "luau." They are parboiled with baking soda or cooked with fat meat to destroy the acidity.

The cultivation and use of taro in Hawaii appears to be slowly decreasing, although in 1913 it was estimated that the total planting was somewhat greater than 1,500 acres. It is reckoned as fourth in importance among the crops cultivated, sugarcane, rice, and pineapple exceeding it. Taro-culture is of two general types, water and upland, and a different set of varieties is grown for each. The length of season required to grow a crop is about one year, although some varieties require longer and some mature in less time. Propagation is by a "huli," which consists of the top of a corm or cornel with 7 or 8 inches of the inner petioles still attached. Planting is undertaken at any time of the year.

In water culture the hulis are placed rather close together, often no more than a square foot being allowed for each plant. The cultural treatment varies greatly and is doubtless influenced by the water-supply, water being often scarce. The soil is puddled in order to prevent too rapid seepage. In some cases the land is rested for several weeks between crops, but more often

replanting is made at once. Again, water is sometimes withheld for two to four weeks after planting, while at others the ground is not allowed to dry. At harvest-time the laborers wade into the mud and water and pull up the taro plants by the roots. The roots are then removed from the corms, the outer leaves stripped off, and hulis made from the tops as already described.

The practice in growing upland taro in Hawaii also varies considerably in the spacing of the plants, they being sometimes planted in small groups, at regular intervals, though more commonly in regular rows. The harvesting is performed by hand in much the same manner as described for water taro, a simple tool being used, however, in lifting the plants. Upland taro can be grown only where the rainfall is abundant and well distributed throughout the year, hence its culture is limited to certain localities.

The dasheen.

A variety of this same species of taro, *Colocasia esculenta*, known as the Trinidad dasheen (Fig. 3777), was introduced into the United States for culture in the South, in 1905, it having been previously brought from the island of Trinidad to Porto Rico by O. W. Barrett. This variety,

which has come to be known simply as "dasheen," is thought to have come originally from China, as its name, a corruption from "de la Chine" or "da Chine," indicates. Varieties similar in appearance but inferior in quality exist, some of them known to be of Chinese origin.

The Trinidad dasheen is considered to be one of the most promising crop plants introduced into the United States in recent years, as it is thoroughly adapted for culture in the moist sandy loams of the South Atlantic and Gulf states and, as grown in such soils, is of excellent quality. The crop from each hill when well grown,

consists of one or more large central corms, with a large number of lateral cornels or "tubers" (Fig. 3778). The total yield from one hill in good soil ranges from four pounds to as high as thirty pounds in rare cases. These are cooked for table use like potatoes. They are somewhat drier and have a delicate nutty flavor when they have been grown under suitable conditions and are properly prepared. The color of cooked dasheens varies from white or cream to gray or violet. When grown in heavy or poorly drained lands, however, the quality is usually inferior, in both texture and flavor.

An average of eleven analyses of the dasheen gives 27½ per cent of starch and sugars and 3 per cent of protein. The sugar-content is a little higher than in

3775. Taro—*Colocasia antiquorum*. a, Inflorescence, showing wide-open limb of spathe and long sterile appendage of spadix characteristic of this species. b, Spadix, showing the following areas, beginning above the base: 1, pistillate flowers; 2, abortive flowers which were compressed by the neck of tube of spathe; 3, staminate flowers; 4, sterile appendage.

3776 Taro—*Colocasia esculenta* (*C. antiquorum* var. *esculenta*). a, Inflorescence, showing limb of spathe open to trough-shape and short sterile appendage characteristic of this species. b, Spadix, showing the following areas, beginning above the base: 1, pistillate flowers; 2, abortive flowers which were compressed by the neck of tube of spathe; 3, staminate flowers; 4, sterile appendage.

the white potato, making the dasheen seem slightly sweet by comparison. Like other taros, it is held by many to be easy of digestion as compared with most other starchy foods.

In the United States, the dasheen is at present grown exclusively as an upland crop, that is, not under flooded conditions as other taros are usually grown in Hawaii. The crop requires about seven months of warm frostless weather fully to mature. It has been grown with best results in a moist but well-drained rich sandy loam. Heavy soils produce a low quality of corm and tuber, and often a poor yield. Muck soils, if they contain a moderate amount of moisture, usually produce a heavy crop of dasheens but of poor quality for table use. Dry soils of any kind are useless for dasheens.

Planting should be made in the early spring, just so that the last spring frost will be past before the plants are up. In central Florida, it is made about the middle of March and farther north, up to early April. Cormels, or "tubers," two to four ounces in weight, are generally used for planting, although smaller ones may be used. Larger tubers, small corms, or the upper parts of larger corms may also be planted when available. The character of soil is of greater importance than the size of tuber planted. The tuber is planted about 2 inches below the surface. The plants are spaced 4 by 3 or 3½ by 3½ feet, on level ground except where there is danger from standing water, when planting should be done on ridges. With level planting the soil is gradually drawn toward the plants in cultivating during the latter half of the season. The large leaves shade the ground almost completely by midseason if the soil conditions are good.

The crop matures in late October and early November in the southern United States. Harvesting is performed with a spade or with team and plow. Dasheens keep well when properly handled and stored. The entire subject is treated at length in bulletins of the United States Department of Agriculture.

ROBERT A. YOUNG.

TARRAGON (*Artemisia Dracunculus*, which see) is a close relative of wormwood (*A. Absinthium*). It is a perennial composite herb native of the Caspian Sea region and Siberia, and is cultivated as a culinary herb in western Europe. Its lanceolate entire leaves and small inconspicuous and generally sterile blossoms are borne upon numerous branching stems, 2 to 3

feet tall. Its green parts, which possess a delicate aromatic flavor resembling anise, are widely used for seasoning salads and for flavoring vinegar, pickles, and mustard. The essential oil of tarragon and tarragon vinegar are articles of commerce, the crop being grown extensively in southern France for this purpose. The

3778. A hill of dasheen. The large central corm, with part of leaf-stems still attached, is surrounded by the cormels, or tubers, just as they grow.

former is obtained by distillation of the green parts, the latter by simple infusion in vinegar. The best time to gather the crop for distillation or infusion is when the first flowers begin to open, since the plants have then a larger percentage of oil than before or after. From 300 to 500 pounds of green parts, according to seasonal and other conditions, are needed to produce one pound of oil.

As cultivated tarragon rarely produces viable seed, the plant is propagated by cuttings of both old and green wood and by division of the roots. Cuttings may be taken at any convenient time, but the best time for the division is when the plants have just begun to grow in the spring. Tenacious and wet soils should be avoided and only loams of medium texture and of poor quality in sunny situations chosen. The plants may be set, either in the spring or in the autumn, 1 foot apart and cultivated like sage or mint. The flower-stems should be removed as soon as seen, as this will force greater growth of leaves. The green parts may be gathered at any time, after the plants have become established, and used fresh. Dried tarragon is nearly as useful as green, but there is little market for it, less even than for the leaves. At the approach of winter, especially in cold and snowless climates, the stems should be cut down and the plants covered with litter or leaves. The position of the beds should be changed every three or four years. Tarragon is less cultivated in America than it deserves. Most of our tarragon vinegar comes from France.

A wholly different plant, *Tagetes lucida*, is much like tarragon in flavor and has been used as a substitute for it.

M. G. KAINS.

3777. Full-grown plant of dasheen, the variety of taro grown in the United States.

TASMANNIA (named after Abel Jansen Tasman, navigator, for whom the island Tasmania is named). Now considered a synonym of *Drimys*. One species, *Drimys aromatica*, Muell. (*Tasmannia aromatica*, R.Br.), is sometimes mentioned in horticultural literature: small tree or a bushy shrub with pinkish fls., elliptic-oblong or oblong-lanceolate lvs. and aromatic pea-size berries. Victoria, Tasmania. B.R. 31:43.

TAVARÈSIA (derivation unexplained). *Asclepiadaceae*. Succulent stapelia-like perennials, branching at the base: sts. 6-12-angled, angles tuberculate, toothed, each tubercle with 3 bristles: fls. large and showy, in sessile cymes at base of young sts.; calyx 5-parted; corolla

3779. *Taxodium distichum*.—
Bald cypress.

globular. Trop. and S. Afr. B.M. 6203. G.C. III. 27:210 (both as *Decabelone Barklyi*). G.W. 15, p. 117.

TAXODIUM (alluding to the similarity of the foliage to that of *Taxus*). Syn., *Glyptostrobus*, *Schubertia*. *Pinaceae*. Ornamental woody plants, grown chiefly for their graceful feathery foliage.

Deciduous or evergreen trees or shrubs: lvs. alternate, linear, usually 2-ranked, falling off in autumn or the second year together with the short lateral branchlets: fls. monocious, small; staminate fls. catkin-like, consisting of spirally arranged anthers, with 4-9 anther-cells and forming terminal panicles; pistillate fls. solitary or in pairs at the ends of branchlets of the previous year, composed of imbricated scales bearing 2 ovules inside at the base: cone globose or nearly so, maturing the first year, consisting of spirally arranged woody scales enlarged at the apex into an irregularly 4-sided disk with a mucro in the middle and toward the base narrowed into a slender stalk; 2 triangular, winged seeds under each scale; cotyledons 4-9.—Two species in N. Amer. and 1 in China.

Of the three species, the only one well known in cultivation is the bald cypress, *T. distichum*, a tall pyramidal deciduous tree with small linear two-ranked leaves and small globose cones. It is hardy as far north as New England and is a very desirable tree for park planting. Its light green feathery foliage and the narrow pyramidal habit which it usually retains in cultivation give it a very distinct appearance. In its native habitat it forms in old age a broad round-topped head sometimes 100 feet across and has the trunk much enlarged at the base by huge often hollow buttresses projecting in all directions and terminating in long horizontal roots. From these roots spring the peculiar cypress knees, pyramidal protuberances composed of a very light, soft, spongy wood and spongy bark. These sometimes attain a height of 10 feet and with age usually become hollow. From the under side of the horizontal roots large anchor-roots are sent perpendicularly into the earth and help to anchor the tree firmly in the swampy yielding soil. The knees are thought by some to be formed for the purpose of strengthening this root-system, since they are chiefly found opposite to the anchor-roots, but their main purpose is probably to bring air to the roots during the several weeks or months when the swamps are covered with water. The

knees always grow high enough to rise above the surface of the water (see, also, G. F. 3, pp. 2, 21, 22, 57). The bald cypress is one of the most valuable timber trees of North America. The wood is brown, light and soft, close and straight-grained, but not strong; it is easily worked, durable in the soil and much used for construction. The bald cypress thrives best in moist sandy soil, but also does well in drier situations. The habit seems to depend somewhat on the degree of moisture; in drier soil the head is more narrow-pyramidal, in moist soil broader and more spreading. Propagated by seeds sown in spring and the varieties by grafting on seedling stock early in spring in the greenhouse; also by cuttings in sand constantly saturated with water or grown in water alone, under glass.

distichum, Rich. (*Cupressus disticha*, Linn. *Schubertia disticha*, Mirbel). **BALD CYPRESS**. **DECIDUOUS CYPRESS**. Fig. 3779. Tall deciduous tree, becoming 150 feet high, with a buttressed trunk usually 4-5, but sometimes attaining 12 ft. or more in diam., usually hollow in old age; bark light cinnamon-brown, flaky: branches erect or spreading, distichously ramified, forming a narrow pyramidal head, becoming at maturity broad and rounded, with slightly pendulous branches: lvs. narrowly linear, acute, thin, light green, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: panicles of the purplish staminate fls. 4-5 in. long: cone almost globose, rugose, about 1 in. across and destitute of mucros at maturity, seed $\frac{1}{4}$ in. long. March-May. Del. to Fla., west to Mo. and Texas, in swamps, along the larger rivers and over calcareous rocks. S.S. 10:537. G.F. 3:7; 10:125. G.C. II. 11:372; 18:361; III. 7:325, 328; 14:659; 24:320; 54:251. Gn. 76, p. 562. F.S.R. 2, p. 163. Gn.M. 2:11. F.E. 27:71. Gng. 2:225; 5:1. G.M. 39:875. M.D.G. 1896:303. S.H. 2:541. G.W. 14, p. 512.—An interesting natural variety is: Var. *imbricarium*, Nutt. (*T. adscendens*, Brongn. *T. microphyllum*, Brongn. *T. distichum* var. *erectifrons*, Schelle). Smaller tree with deeply furrowed bark: branches upright: lvs. subulate, $\frac{1}{2}$ - $\frac{1}{2}$ in. long, more or less upright and rather appressed. Va. to Fla. and Ala., in lakes, ponds, small rivers, apparently always over a clay subsoil. B.M. 5603. F. 1871, p. 60. Var. *pendulum*, Carr. (*T. distichum sinense pendulum*, Loud. *Glyptostrobus pendulus*, Endl. *G. sinensis*, Hort.). A form of the preceding variety with pendulous branches. Var. *pyramidalum*, Carr. Narrow pyramidal form with short

3780. Old English yews that have reached maturity.—*Taxus baccata*. Addison's walk, at Glasnevin, Ireland.

ascending branches. Var. *fastigiatum*, Knight. With slender, upright, virgate branches sparingly ramified. Var. *nanum*, Carr. Dwarf, shrubby form, with numerous short branches. Var. *nutans*, Ait. Branches spreading, long and slender, nodding at the tips. F.E. 29:9 (as *T. distichum pendulum*). Var. *microphyllum*, Carr. Shrub, with short spreading branches; the lateral

branchlets with typical foliage, those of the longer branches gradually passing toward the end into small, scale-like, imbricate lvs.

mucronatum, Ten. (*T. mexicanum*, Carr. *T. distichum* var. *mexicanum*, Gord. *T. distichum* var. *mucronatum*, Henry). MONTEZUMA CYPRESS. Similar to the preceding species: taller evergreen tree, occasionally 170 ft. high with a trunk 20 ft. or more in diam.: lvs. shorter, obtusish and mucronulate, falling with the branchlet the second year: staminate fls. and cones larger. Mex. G.F. 3:155. G.C. III. 12:647.—Sometimes planted in S. Calif.

T. heterophyllum, Brongn. (*Glyptostrobus heterophyllus*, Endl.). Shrub, 10 ft. high: lower branches pendulous: lvs. linear and scale-like on the same plant: cones ovoid, $\frac{3}{4}$ in. long. China. Tender and rarely cult. Often confounded with varieties of *T. distichum*.

ALFRED REHDER.

TÁXUS (ancient Latin name of the yew). *Taxaceæ*, formerly named in the *Coniferae*. YEW. Ornamental woody plants, grown for their dark green foliage and the scarlet berry-like fruits.

Evergreen trees or shrubs: lvs. linear, without resin-ducts, pale or yellowish green beneath, usually 2-ranked: fls. usually dioecious, solitary and axillary, rarely terminal, small, appearing in early spring; staminate globose, composed of 4-8 stamens each, with 3-8 anther-cells attached to the peltate connective; pistillate consisting of a single terminal ovule with several bracts at the base: seed a bony nut surrounded

shade well. Large plants may be successfully transplanted if it is possible to secure a sufficient ball of earth with the roots. Propagation is by seeds, which do not germinate until the second year, and by cuttings taken early in autumn and kept during the winter in a cool greenhouse or frame; the varieties also often by grafting on the type in early spring in the greenhouse, or sometimes by layers. Plants raised from cuttings grow more slowly than grafted ones and cuttings of the type rarely grow into trees but usually into low-spreading shrubs (see M.D.G. 1898:565).

baccata, Linn. Fig. 3780. Tree, attaining 60 ft., with a usually short trunk, occasionally 8 ft. or more in diam.: bark reddish, flaky, deeply fissured in old trees: branches spreading, forming a broad, low head; branchlets somewhat pendulous: lvs. 2-ranked, linear and usually falcate, shortly acuminate, with prominent midrib, dark green above, pale beneath, $\frac{3}{4}$ -1 $\frac{1}{4}$ in. long or shorter in some varieties: fr. $\frac{1}{8}$ - $\frac{1}{2}$ in. across, with almost globose disk, about a third longer than the broadly ellipsoid brown seed $\frac{1}{4}$ in. long. Eu. and N. Afr. to Himalayas. G.C. II. 23:309; III. 29:262. Gn. 27, p. 578; 35, pp. 37, 37. G.F. 9:265. F.S.R. 3, p. 59. G.W. 10, p. 249; 11, p. 304; 13, pp. 67, 175. Gng. 1:309.—Many garden forms have originated in cult.; the following are the most important: Var. **adpressa**, Carr. (*T. parvifolia*, Wender. *T. brevifolia*, Hort., not Nutt. *T. tardiva*, Laws. *T. baccata tardiva*, Pilger). Shrub or low tree of irregu-

3781. Spray of *Taxus canadensis*. ($\times \frac{1}{2}$)

or almost inclosed by a fleshy cup-shaped scarlet disk; cotyledons 2.—Six species are known. They are distributed throughout the northern hemisphere and in Amer. south to Mex. They are all very closely allied and have been considered geographical varieties of a single species. The wood is heavy, hard, close-grained, strong, elastic, and of reddish color. It is highly valued for cabinet-making and turning, and before the invention of gunpowder was in great request in England for the manufacture of bows. The foliage is poisonous to horses and cattle, but the berries are not.

The yews are evergreen, usually small slow-growing trees or shrubs, with 2-ranked linear dark green leaves, insignificant flowers and showy berry-like red fruits. The best-known species is *T. baccata*, which is hardy as far north as Rhode Island and northwestern New York, and in some forms as far as Massachusetts, while *T. cuspidata* and *T. canadensis* are considerably harder and thrive as far north as Canada; the other species are little known in cultivation. The yews are very desirable evergreens for park planting; they are densely clothed with dark green foliage and the pistillate plants are particularly beautiful in autumn when loaded with scarlet fruits. They are well suited for hedges and easily trimmed into any desired shape. They were formerly much used for fantastic topiary work (see e. g., G.C. II. 2:264, 265).

That the typical tree-like form of the yew is nowadays not much planted is chiefly due to its slow growth, but the numerous mostly shrubby garden forms are popular plants for small gardens. The yews thrive best in a moderately moist sandy loam and endure

lar habit, with long spreading branches: lvs. oblong, obtusish, mucronulate, $\frac{1}{2}$ - $\frac{1}{2}$ in. long: disk of fr. shorter than the seed. R.H. 1886, p. 104. Gn. 35, p. 37. Very distinct form. Var. **adpressa erecta**, Nichols. (var. *adpressa stricta*, Beissn.), has the foliage of the preceding, but erect branches forming a columnar bush. Var. **aurea**, Carr. (var. *elavstonensis aurea*, Beissn.). Lvs. golden yellow, more brightly colored at the tips and margin. This form has proved hardier than the type in New England. F.E. 20:703. Var. **argentea**, Loud. (var. *elegantiissima*, Hort.). Lvs. striped straw-yellow or sometimes whitish. Var. **Dovastonii**, Loud. Branches wide-spreading, nodding at the tips: lvs. dull green, short and abruptly mucronulate. G. 3:89. A very handsome form. Var. **Dovastonii aureo-variegata**, Beissn., is a form with the lvs. variegated with yellow. Var. **erecta**, Loud. (var. *stricta*, Hort.). Bushy form, with slender, upright branches and branchlets: lvs. narrower and smaller than in the type. Var. **ericoides**, Carr. (var. *microphylla*, Hort.). Dwarf form, with slender branches and small and very narrow, pointed leaves. Var. **fastigiata**, Loud. (var. *hibernica*, Hort.). Strictly fastigiate form, with stout crowded upright branches and branchlets: lvs. spirally arranged around the branches, dark glossy green. Gn. 35, p. 36; 40, p. 62. R.H. 1886:105. G. 2:85. F.E. 18:397; 33:315. G.W. 1, p. 349; 8, p. 301; 10, p. 393. One of the most desirable evergreens of columnar habit for formal gardens. Var. **fastigiata variegata**, Carr. Less vigorous and more tender: lvs. marked yellowish white. Var. **fastigiata aurea**, Standish. Young growth golden yellow. Var. **Fisheri**, Hort. Some of the lvs. deep yellow, others

green. Var. *glauca*, Carr. Vigorous form, with longer and narrower lvs. dark green above and with a glaucous bluish tint beneath. Var. *Jacksonii*, Gord. (var. *pendula*, Hort.). Branches spreading, pendulous at the tips, with more or less incurved lvs. Var. *luteo-baccata*, Pilger (var. *fructu luteo*, Loud.). With yellow fr. Gn. 35, p. 37. R.H. 1886, p. 104. Var. *procumbens*, Loud. Prostrate shrub, with elongated and much ramified branches. Var. *repandens*, Hort. A low form with long wide-spreading branches and dull bluish green lvs. Var. *Washingtonii*, Beissn. Vigorous form, with longer lvs., partly colored golden yellow.

cuspidata, Sieb. & Zucc. (*T. baccata* var. *cuspidata*, Carr.). Tree, attaining 50 ft., with a trunk usually 2 ft. diam.: bark bright red: branches ascending: lvs. usually falcate, thickish, distinctly and abruptly mucronate, dark green above, pale fulvous green or pale green beneath, $\frac{1}{2}$ –1 in. long: fr. with ovoid seed slightly 3–4 angled and $\frac{1}{2}$ in. long. Japan. S.I.F. 1:15. Very similar to *T. baccata*, but branches stouter and lvs.

3782. *Taxus brevifolia*. ($\times \frac{1}{6}$)

darker green above and tinged yellowish beneath, somewhat broader, more abruptly mucronate and thicker in texture. Var. *nana*, Rehd. (var. *brevifolia*, Hort. Amer. Var. *compacta*, Bean). Shrubby form with spreading branches densely clothed with short branchlets: lvs. somewhat shorter and duller, ascending and not or scarcely 2-ranked: slow-growing, rather compact while young, but with age becoming more open. C.L.A. 11:308. F.E. 29:409. Gn.M. 2:11. Var. *densa*, Rehd. Low form making a dense sometimes almost hemispherical bush with ascending branchlets: lvs. like those of the preceding form. Var. *chinensis*, Rehd. & Wilson (*T. baccata* var. *chinensis*, Pilger). Lvs. more falcate, lighter green, $\frac{3}{4}$ – $1\frac{1}{4}$ in. long, convex above with the midrib very slightly raised: seeds broadly ovoid, slightly compressed, slightly 2-angled. Cent. and W. China.—This variety fruits very profusely. The plant offered as var. *capitata* does not differ from typical *T. cuspidata*.

canadensis, Marsh. (*T. baccata* var. *minor*, Michx. *T. baccata* var. *canadensis*, Gray. *T. minor*, Brit.). Fig. 3781. Prostrate shrub, with wide-spreading slender branches, rarely more than 3 ft. high: lvs. shorter and narrower, less crowded and of a lighter, more yellowish green than those of *T. baccata*, assuming in winter usually a reddish tint: fr. ripens about 2 months earlier than that of *T. baccata*; seeds depressed, broader

than long: fls. monœcious (at least usually). Newfoundland to Man., south to Va. and Iowa. B.B. (ed. 2) 1:67. V. 14:252. Gn.M. 2:22.—In cult. it becomes usually a more upright and less straggling shrub.

brevifolia, Nutt. Fig. 3782 (adapted from Pacific R. R. Report). Tree, 40–50 or occasionally 80 ft. high, with slender horizontal or somewhat pendulous branches forming a broad, open, pyramidal head: lvs. distinctly 2-ranked, sharply pointed, dark yellowish green, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: seeds ovoid, 2–4 angled. Brit. Col. to Calif. S.S. 10:514.—Probably as hardy as *T. baccata*.

T. floridana, Chapm. Bushy tree, 25 ft. high or sometimes shrubby: lvs. slender, $\frac{1}{4}$ –1 in. long, dark green. Fla. S.S. 10:515. —*T. koraiensis*, Hort. = *Cephalotaxus Harringtonia* var. *fastigiata*. —*T. Wallichiana*, Zucc. Tree, to 100 ft.: lvs. gradually long-acuminate, 1– $1\frac{1}{2}$ in. long. Himalayas, Malay Archipelago, Philippine Is. Apparently not in cult.

ALFRED REHDER.

TCHIHATCHËWIA (named for Count Paul Tchihatchef). *Cruciferae*. Hardy perennial herb (possibly of shorter duration), suitable for the rockery. Plant very hispid: root thick: st. stout, leafy, pilose: fls. purple; sepals erect, the lateral ones saccate at base; petals clawed, blade minute; stamens without teeth: silique pendulous, obovate, compressed, broadly membranaceous-marginate, 1-celled, 2-seeded.—One species, Armenia. Sometimes spelled with another c, Tchihatchewia.

isatidea, Boiss. St. very stout, 6–10 in. high: lvs. $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long, spreading and recurved, the upper ones gradually larger, sessile, linear, hispidly hairy: fls. bright rosy red, vanilla-scented, disposed in a dense, hemispherical, much-branched corymb, 4 in. across. Armenia. B.M. 7608. G.C. III. 42:324. R.H. 1895, p. 352.

TEA: *Thea*. T., Oswego: *Monarda didyma*. T., Paraguay: *Ilex paraguayensis*.

TEAK: *Tectona*.

TEASEL: Species of *Dipsacus*.

TÉCOMA (abridged from the Mexican name *Tecomaxochitl*). Including *Stenoldibum*. *Bignoniaceae*. Ornamental shrubs, grown for their showy flowers.

Upright plants with herbaceous shoots: lvs. opposite, odd-pinnate, rarely simple; lfts. serrate, membranous: fls. in terminal panicles or racemes; calyx tubular-campanulate; corolla funnelform or funneliform-campanulate; stamens included, with diverging anther-cells and enlarged foliaceous connective; disk cupulate, crenate: caps. linear, with leathery valves; seeds narrow-elliptic, with 2 large thin wings.—About 5 species from Fla. and Texas to Argentina. The trumpet-vine, commonly referred to Tecoma, will now be found under *Campsis*.

The tecomas are upright shrubs with pinnate deciduous or subpersistent foliage and large and showy usually yellow flowers in terminal clusters. They stand but little frost and are well suited for cultivation in Florida and southern California. Propagation is by seeds which are usually freely produced and by greenwood cuttings under glass.

The yellow elder, *T. stans*, grows exceedingly well on high pine-land and is perfectly at home in Florida, attaining an immense size if well fertilized and mulched, dense masses 18 to 25 feet high and as much through being not at all rare. This tecoma is the glory of the south Florida gardens in autumn, as is the beautiful *Bauhinia purpurea* in April. No shrub is better adapted for the new settlers in the sandy pine-land gardens. When covered with its large fragrant flowers it is visited by numberless hummingbirds and insects. Owing to its rapid growth and dense foliage from the ground, the yellow elder is highly valued as screen for

unsightly fences and buildings. This tecoma ripens its seed so abundantly that hundreds of seedlings come up around the old plant. The value of this shrub, blooming so late in autumn, cannot be overestimated. *T. mollis*, incorrectly known to the trade as *T. stans* var. *velutina*, also does well, but being a native of Guatemala it is much less hardy than the former. The growth is more upright and stiff, the leaflets are much larger, less serrate, and much darker green and the flowers, which are borne in terminal panicles, are smaller and without fragrance and the color is a much lighter yellow. It also flowers several weeks earlier than *T. stans*. The foliage looks crimped and often blackish, being attacked by a kind of aphid and by several fungi. *T. Smithii* is said to be a hybrid between *T. mollis* and *Tecomaria capensis*, raised near Melbourne, Australia, by Edwin Smith. The plant comes true from seed, and seedlings flower when about a year old, beginning to open their large clusters of yellow and reddish trumpets in April and continuing with short intervals until cut down by frost in December. (H. Nehrling.)

A. Fls. pure yellow, funnel-form-campanulate, abruptly contracted above the base.

B. Lvs. glabrous or nearly so.

stans, Juss. (*Stenolobium stans*, Seem.). **YELLOW ELDER.** Upright shrub: lvs. odd-pinnate; lfts. 5-11, almost sessile, oblong-ovate to lanceolate, acuminate, serrate, glabrous, 2-5 in. long and $\frac{3}{4}$ -1 $\frac{1}{4}$ in. broad: fls. in large, terminal racemes or panicles; corolla funnel-form-campanulate, yellow, 1 $\frac{1}{2}$ in. long; anthers pubescent; calyx with 5 short teeth: caps. linear, 5-7 in. long. Sept.-Dec. S. Fla. to W. Indies and S. Amer. B.M. 3191.—Sometimes called yellow bignonia. Fls. fragrant. Var. *angustata*, Rehd. (*Stenolobium incisum*, Woot. & Standley). Lfts. 7-11, lanceolate to linear-lanceolate, sharply or incisely serrate with flaring teeth, 1-3 in. long and $\frac{1}{4}$ - $\frac{1}{2}$ in. broad. Texas, Ariz., and Mex. This variety is harder than the type, which is sometimes cult. as *T. sambucifolia*; the true *T. sambucifolia*, HBK., from Peru, which has glabrous anthers, is probably not in cult.

BB. Lvs. villous or tomentose beneath.

mollis, Humb. & Bonpl. (*T. velutina*, Lindl. *T. stans* var. *velutina*, Hort.). Similar to the preceding, but pubescent: lfts. 5-9, oblong-ovate, acuminate, less deeply serrate or almost entire, villous-pubescent on both sides or only beneath, 2-4 in. long: fls. like those of the preceding, but smaller and paler and not fragrant. Mex. to Chile and Peru.—It lasts in bloom much longer and the fls. keep well in water, a rare occurrence in this genus.

AA. Fls. yellow and red, tubular-funnel-form, gradually narrowed toward the base.

B. Lfts. obtuse or acutish.

Smithii, W. Wats. Fig. 3783 (adapted from The Garden). Upright shrub: lvs. odd-pinnate; lfts. 11-17, oblong, obtuse or acutish, serrate, 1-2 in. long: fls. in large, compound panicles, sometimes 8 in. long and as broad; corolla tubular-funnel-form, with 5 reflexed rounded lobes, bright yellow tinged with orange, 1 $\frac{1}{2}$ -2 in. long. Sept.-Jan. Intro. from Austral. and supposed to be a hybrid of *T. mollis* and *Tecomaria capensis*. G.C. III. 14:649. Gn. 48:23. I.H. 43:55, 107. Gt. 44, p. 52. G.M. 36:627. J.H. III. 42:371.—Blooming in the greenhouse in winter and well suited for cult. in pots. It has been said that it comes true from seed, but plants raised by Franceschi from seed received from the originator had mostly pure yellow fls.

BB. Lfts. acuminate.

Garrócha, Hieron. Glabrous small shrub: lvs. 3 $\frac{1}{2}$ -5 in. long; rachis narrowly winged; lfts. 7-11, short-stalked, oblong-ovate, acuminate, serrate, 1-2 in. long:

fls. in slender racemes forming terminal panicles 4-6 in. long; calyx with long-acuminate teeth; corolla about 2 in. long, yellow with scarlet tube, slender, very gradually narrowed toward the base, limb $\frac{3}{4}$ -1 in. across; anthers slightly exceeding the mouth: caps. 2 $\frac{1}{2}$ -4 in. long. July-Aug. Argentina.—A smaller and more graceful plant than *T. stans*, strikingly handsome with its bright yellow and scarlet fls.

T. æsculifolia, DC.—*Tabebuia æsculifolia*.—*T. amboinensis*, Blume. Evergreen climbing shrub: lvs. odd-pinnate with usually 5 elliptic-obovate lfts. 3-3 $\frac{1}{2}$ in. long; fls. tubular-funnel-form, red, 3-4 in. long, in lateral racemes. Amboina. Once offered by John Saul, but has probably now disappeared from cult. It is not a true *Tecoma* and belongs possibly to *Pandorea*.—*T. australis*, R. Br.=*Pandorea australis*.—*T. Brycei*, N. E. ALFRED REHDER.

TECOMARIA (name derived from *Tecoma*, alluding to its affinity). *Bignoniaceæ*. Warm-country plants, grown for their showy bloom.

Evergreen shrubs with slender, often sarmentose branches: lvs. opposite, odd-pinnate; lfts. serrate: fls. in terminal panicles or racemes; calyx campanulate, regularly 5-toothed; corolla funnel-form, slightly curved; stamens mostly exserted, with pendulous diverging cells; disk cupulate: caps. linear, compressed.—Five species in Cent. and S. Amer. and in S. Afr.

The tecomarias are half-climbing or nearly upright

shrubs with handsome pinnate foliage and yellow, orange, or scarlet flowers in rather dense terminal clusters. They can be grown outdoors only in subtropical regions. Of the several species in cultivation only *T. capensis* seems to be planted in southern California and Florida. Moderate pruning in spring insures a more profuse blooming. Propagation is by seeds and by cuttings under glass in spring or in midsummer.

The cape honeysuckle, *T. capensis*, grows most luxuriantly in Florida gardens and in those all along the Gulf coast. It is usually grown on trellises on verandas

3784. *Tectaria cicutaria*.

and piazzas with a southern exposure. Of all the species this is the best and most suitable for verandas, being a dense and compact grower, evergreen, almost constantly in flower, easily kept in health and readily trained into shapely specimens. If the long shoots are cut back severely, the plant can be easily trained into shrub form. These long shoots, usually lying flat on the ground, readily strike root and form an excellent material for propagation. *T. capensis* and *Tecoma Smithii* are the only ones which grow and flower fairly well as pot-plants in northern greenhouses. They need good soil and rather large pots to do well. If not well cared for they lose most of their foliage and look poor and unshapely. (H. Nehrling.)

capensis, Seem. (*Tecoma capensis*, Lindl.). CAPE HONEYSUCKLE. Half-climbing or nearly upright shrub: lvs. odd-pinnate; lfts. 7-9, broadly oval to ovate, acute, serrate, glabrous, $\frac{1}{2}$ -2 in. long; fls. in peduncled terminal racemes; corolla tubular, curved, with 4-parted spreading limb, the upper lip emarginate, orange-red to scarlet, about 2 in. long; calyx 5-toothed: caps. linear, 1-2 in. long. Aug.-Nov. S. Afr. B.R. 1117. L.B.C. 17:1672. R.H. 1895, p. 108.

T. fulva, Baill. (*Tecoma fulva*, Don). Evergreen upright shrub to 15 ft. high: lvs. odd-pinnate, with 9-13 small, ovate, toothed lfts.: fls. in terminal panicles, tubular-funnelform, slender, yellow, tinged red, $1\frac{1}{2}$ in. long; stamens slightly exserted. Peru. B. M. 4896. F.S. 11:1116.—*T. shirensis*, Schum. (*Tecoma shirensis*, Baker. T. Whyte, C. H. Wright). Similar to *T. capensis*. Shrub, to 10 ft.: lfts. 9-13, ovate, serrate, 1-1 $\frac{1}{2}$ in. long; corolla about 2 in. long, orange-yellow, the limb marked with red stripes. Nyassaland. B.M. 7970.

ALFRED REHDER.

TECOPHILÆA (named for Tecophila Billotti, daughter of a botanist). *Amarylloideæ*. CHILEAN CROCUS. Bulbous plants, useful for blooming in pots indoors early in the spring. Lvs. radical, few or 1, inclosed in a long scarios sheath at the base, blade spreading, linear or lanceolate; scape included with the lvs. at base in the sheath, otherwise leafless, 1-fl. or laxly few-fl.: fls. blue; perianth campanulate, 6 segms.; stamens 3 perfect and 3 staminodia; ovary 3-celled: caps. conical toward the top, loculicidally dehiscent.—Two species, Chile. The botanical position of *Tecophilæa* is open to discussion, but the inferior ovary seems to take it out of the Liliaceæ, with which it has

been placed by some writers. The plants are useful for blooming in pots indoors early in spring. *T. violæflora*, Bert., does not appear to be introduced.

cyanocrdus, Leyb. (sometimes written *T. cyano-crocea*). Scapes 1-3, erect, 3-6 in. high, 1-fl.: lvs. 2-3, linear-canaliculate and undulate: fl. azure-blue with white throat, about $1\frac{1}{2}$ in. long, with a narrow tube and obovate segms. G. 37:183. R.H. 1900:70. Var. *Leichtlinii*, Hort., has fls. deep blue with no trace of yellow; said by some to have a white center. Var. *Régelii*, Baker (not known to be in the trade), has longer peduncles, longer and narrower scarcely undulate lvs., and narrow oblong segms. Species hardy at New York City in protected places, but usually the plants do not thrive more than a year or two; they ought to do better farther south. Blooms very early in spring. Fls. violet-scented.

F. TRACY HUBBARD.†

TECTARIA (Latin for cover, the indusium having shield-shaped coverings). *Polypodiaceæ*. A group of ferns, mostly of large and coarse habit, with superior reniform or heart-shaped indusia fixed by the sinus, as in *Dryopteris*, but with veins uniting freely to form areoles with free included veinlets.—About 25 species are known, largely from the E. Indies, a few from Trop. Amer. By some included in *Polystichum*.

decurrens, Copeland. Lf.-stalks narrowly winged from a creeping rootstock: lvs. 2-4 ft. long, 1 ft. or more wide, cut down to a winged rachis and with 4-8 pairs of pinnae 6-12 in. long, 1-2 in. wide: sori large, in 2 regular rows between the principal veins. India to Polynesia.

cicutaria, Copeland. Fig. 3784. Caudex stout, erect, scaly above: lvs. 6-8 in. to $1\frac{1}{2}$ ft. long; pinnae horizontal, subsessile from a rather broad truncated base, 2-3 in. long: sori on disk of larger pinnules in 2 rows, oblong, those on terminal narrow segms. solitary, quite marginal. Trop. Amer.

TÉCTONA (derived from *Tekka*, the Malabar name of *T. grandis*). Syn., *Thèka*. *Verbenaceæ*. Tall trees, stellately tomentose, including the well-known teak-wood, sometimes grown in the warmhouse as a curiosity. Lvs. opposite or ternately verticillate, large and entire: cymes dichotomous, many-fl., arranged in a large terminal panicle: fls. small, white or bluish, sessile; calyx campanulate, shortly 5-6-cleft, inflated in fr.; corolla-tube short, limb spreading, 5-6-cleft; stamens 5-6; ovary fleshy, 4-celled, cells 1-ovuled: drupe inclosed in the calyx, 4-celled; endocarp bony.—Three species, Asia, India, Burma, Malaya, and Philippines.

grandis, Linn. TEAK. Tree, 80-150 ft. high: branchlets quadrangular: lvs. 8-12 in. (of seedlings sometimes 3 ft.), ovate, cuneate at both ends, close tomentose beneath: fls. white or bluish, numerous, but only a few fertile, in panicles 18 in. diam.; calyx stellately white-tomentose, 1 in. diam. in fr. when it is ovoid or subpyramidal; corolla scarcely $\frac{1}{2}$ in. long. India, Malaya.—The timber of this important tree is much used in ship-building because of its durability, great strength, and the ease with which it can be worked. Not planted in this country except experimentally.

F. TRACY HUBBARD.

TEEDIA (named for J. G. Teede, German botanist). *Scrophulariaceæ*. Glabrous or pubescent shrubs, grown in the greenhouse. Lvs. opposite, ovate, entire: peduncles in the upper axils, bearing a few-fl. cymose infl.: fls. rose, rather small; calyx deeply 5-cleft, lobes narrow; corolla-tube cylindrical, limb spreading, 5-lobed, lobes subequal, rotundate; stamens 4: berry subglobose, indehiscent.—Two species, S. Afr. The foliage of both species has an objectionable odor.

lucida, Rud. Glabrous: st. 4-cornered: lvs. oblong-ovate, acuminate, 2 in. long, decussate; petioles winged

panicles leafy, decussate: fls. rosy pink: seeds many, small. S. Afr. B.R. 209.—This species was intro. into S. Calif. some years ago, but appears to have lost favor. It is said to act like an annual there, but seeds freely and prefers half shade.

T. pubescens, Burch., grows about 2 ft. high, rusty-pubescent or villous: lvs. ovate or elliptic, often broader than those of *T. lucida*.

F. TRACY HUBBARD.

TELANTHERA (name refers to the fact that all ten parts of the staminal cup are equally developed). *Amarantaceæ*. **ALTERNANTHERA**. Small much-used bedding plants, popular in design work because they are compact and stand shearing well.

Apparently all the alternantheras used by gardeners as bedding plants belong to the genus *Telanthera*, which is distinguished from the true genus *Alternanthera* by having 5 anther-bearing stamens and 5 elongated antherless staminodia united into a cup or tube. In *Alternanthera* the tube is short or almost none, the anther-bearing stamens sometimes less than 5, and the staminodia short or none. Of *Telantheras* there are 40-50 species, mostly herbs, in Trop. Amer. and 1 in W. Afr. The lvs. are entire, ovate to elongated, opposite: fls. small, usually in dense heads in the axils, whitish or sometimes colored, perfect, each subtended by 2 bractlets. In Engler & Prantl, *Die Natürlichen Pflanzenfamilien*, Schinz retains *Telanthera* under *Alternanthera*, not dividing the group.

The alternantheras of gardeners are much used in carpet-bedding and for ribbon-borders, because of their low compact growth, the bright colors of the foliage, which holds its character throughout the season, and the ease with which they withstand shearing. They are usually kept within 6 inches of the ground. The plants are tender to frost, and grow best in warm sunny places. They comprise the stock plants for the foundation work in carpet-bedding. The flowers are inconspicuous and of no account to the gardener.

The plants are propagated by cuttings or division. In either case, they must be carried over winter in the greenhouse or in hotbeds, preferably in the houses at the North. The plants should be kept at 60° or 65° during winter, and rather dry to hold them more or less dormant. Place them where they will receive only enough light to keep them healthy. (1) Cuttings are usually made in August from strong plants growing in the open. The cuttings may be struck in shallow flats and then wintered in these flats without transplanting. The cuttings should be well established before winter sets in, else they will remain weak. In March or April they may be potted off, preparatory to using them in the open. (2) Division is usually preferred by gardeners who have much bedding to do. The plants are lifted after the first frost, cut back to 3 or 4 inches long, and planted in flats. In March or April, the plants are divided and the parts (with the old roots shortened in) potted or transplanted to other flats. However grown, the plants should have four to six weeks in a hotbed if possible, before they are placed in the open ground. Even in the warm greenhouse they usually make slow growth in March and April.

The botanical status of the garden alternantheras is imperfectly understood, and the group needs careful study from living plants. Various garden names cannot be accounted for at present. The common garden alternantheras appear to have issued from the first three following Brazilian species.

A. Lvs. essentially lanceolate or elliptic.

amœna, Regel. Fig. 3785. Very dwarf: lvs. long-lanceolate or oblong-lanceolate, sometimes

elliptic, acuminate, very short-petioled, the under color mostly green but veined and blotched with red and orange: fl.-heads sessile, single, in pairs or 3's, and terminal. I.H. 12:447; 15:558.—To this apparently belong the garden names *amabilis*, *spectabilis*, *sessilis*, *rosea*, *Reinhardtii*.

AA. Lvs. essentially spatulate.

Betzickiana, Regel (originally, in 1862, spelled as here, but changed by the author in 1862 to *Betzickiana*). Fig. 3785. Plant described as suffruticose and erect, the st. branched at base and terete, adpressed-pilose but becoming glabrous: lvs. narrow, spatulate, narrowed into long petiole, apex acuminate and somewhat mucronate: fl.-heads sessile, single, in pairs or 3's, terminal and axillary; bracts ovate-lanceolate, acuminate, nearly or quite entire; staminodia much shorter than stamens, 2-3-cut at apex.—To this variable species appear to belong the garden names *picta*, *tricolor*, *aurea*, *aurea nana compacta*, *paronychioides*, *versicolor aurea*, *magnifica*, and others. Var. *týpica*, Regel (*Alternanthera paronychioides*, Hort.), is low, 2-3 in. tall, with olive-colored lvs. and the upper ones red at apex. Var. *spathulata*, Regel (*A. spathulata*, Lem.), is 6-8 in. tall, the st. and lvs. red. I.H. 12:445.

versicolor, Regel. Fig. 3785. Usually becoming taller, much branched, and apparently less used for carpet-bedding than the others: lvs. round-spatulate, narrowed into a short petiole, the colors mostly in shades of copper-red or blood-red, with patches of green between the veins: fl.-heads sessile, single or in pairs. I.H. 12:440.

ficoidea, Moq. St. herbaceous, repent at base and ascending, angled and striate, glabrous, or puberulent above and in the lf.-axils: lvs. spreading or deflexed, short-stalked, broadly lanceolate, attenuate and somewhat acute, mucronulate, the margin undulate-repand: heads $\frac{1}{8}$ - $\frac{1}{4}$ in. long, sessile, solitary or in 2's; bracts

3785. Spray of *Telanthera amœna*; also leaf-outlines of a, *T. amœna*; b, *T. Betzickiana*; c, *T. versicolor*. (X1)

acuminate-cuspidate, much longer than outer sepals. Brazil.—The *T. ficoidea*, Hort., may be a form of one of the other species.

L. H. B.

TELÈKIA: *Buphthalmum*.

TELÈPHIUM (an old Greek name). *Caryophyllaceæ*, in Engler & Prantl, Die Natürlichen Pflanzenfamilien; *Ficoideæ*, in Benth & Hooker, Genera Plantarum. **ORPINE.** One species, *T. Imperati*, Linn., is listed abroad as a hardy perennial but it has little to commend it to the cultivator: it is a low plant with woody base and slender prostrate sts., with erect or ascending branches: lvs. many, $\frac{1}{4}$ in. long, alternate or scattered, oval or elliptic, entire: fls. several and inconspicuous, in small compact clusters. Perhaps valuable on banks or as a carpeter.

The genus *Telephium* comprises 2 or 3 species in the Medit. region, being diffusely branched and glaucous herbs: lvs. alternate, paired or opposite, without distinct midrib or nerves: fls. small, in compact terminal clusters, the 5 petals white but not showy; sepals 5, persistent; stamens 5; ovary ovoid, 3-angled and usually 3-celled, the styles 3 and short: fr. a dry caps. included in the calyx.

L. H. B.

TELFÀIRIA (named after Charles Telfair, 1778–1833). *Cucurbitaceæ*. Climbing shrubs, occasionally grown in the warmhouse, of economic value in the tropics. Lvs. digitately compound; lfts. 3–5, oblong, auriculate at the base on the outside; tendrils lateral and 2-cleft: fls. dioecious, medium or large, male pedicels bracteate, pale purple; male racemose, calyx turbinate, lobes lanceolate; corolla rotate, 5-parted, segms. obovate-cuneate, elongated, fimbriate-tendrilled; stamens 3; female solitary, calyx and corolla like male; stamens rudimentary or none; ovary oblong, 3–5-celled: fr. elongate, base swollen, many-seeded; seeds edible.—Two species, Trop. Afr.

pedata, Hook. (*Fewillæa pedata*, Sims). Root stout, fleshy: st. perennial, 50–100 ft. long: lvs. long-petioled; lfts. 3–5 in. long, acuminate, repand-toothed, glabrous except nerves beneath: fls. pale purple, fringed, male 2 in. across; petals obovate-cuneate; female fls. about 4 in. across; ovary obtusely 10-ribbed: fr. fleshy, sometimes weighs 60 lbs., 200–300-seeded; seed 1 in. broad, edible. Zanzibar. B.M. 2681; 2751, 2752.—Intro. into S. Calif. but not successful. The seeds are roundish, about an inch across, and the kernels are sweet to the taste, and are said to be as good as almonds. The negroes of Trop. Afr. boil and eat them. These seeds also yield an abundance of oil which has been said to be equal to olive oil. The fr. becomes $1\frac{1}{2}$ –3 ft. long and 8 in. wide. It is oblong in shape, has 10–12 deep furrows, and is always green. Both male and female fls. are 5-lobed, copiously fringed and purple in color, the females somewhat brownish, with a circular green throat, while the males have a 5-pointed star of green in the middle. The male fls. are about 2 in. across, females 4 in. across, with an ovary 2 in. long. The foliage has an unpleasant smell when bruised.

T. occidentalis, Hook. f., is very similar to *T. pedata*, but the lfts. are all triple-nerved from near the base (those of *T. pedata* all at an angle of 45° from the midrib): fls. smaller. Upper Guinea. Said to be cult. for the seeds which the negroes boil and eat.

F. TRACY HUBBARD.†

TÉLLIMA (anagram of Mitella). *Saxifragaceæ*. Erect rather simple hardy herbaceous perennials, the western American representatives of *Mitella*, well adapted to the wild-garden.

Plants pilose or glandular: lvs. petioled, subrotund-cordate, lobed, dentate; stipules none or adnate to the base of the petioles: fls. pedicelled, nodding, greenish or white, petals rarely reddish; calyx-tube large, dilated or inflated, campanulate, 5-toothed or 5-cleft; petals 5, usually elongate, entire, 3-fid or pinnatifid, sessile or

clawed; stamens 10; ovary semi-superior, conical, 1-celled; caps. membranaceous, 1-celled, many-seeded.—About 10–12 species, W. N. Amer. *Tellima* differs from *Mitella* mainly in the caps., which is 2-beaked in *Tellima*, not beaked in *Mitella*.

A. Petals pinnately cut into long, thread-like segms.

B. Fls. not fragrant.

grandiflora, R. Br. FALSE ALUM ROOT. Height $1\frac{1}{2}$ –2 $\frac{1}{4}$ ft.: lvs. rounded, cordate or angle-lobed and toothed: fls. greenish, becoming pink or red; calyx inflated-bell-shaped, nearly $\frac{1}{2}$ in. long; petals laciniate-pinnatifid, sessile. Calif. to Alaska. B.R. 1178. Var. **rubra**, Hort., grows 1 ft. high, has red foliage and yellow fls.

BB. Fls. fragrant.

odorata, Howell. Height 1–2 ft.: lvs. broadly cordate, obscurely lobed and crenately toothed: fls. red. Wet places near Colombia River.

AA. Petals palmately 3–7-lobed or -parted.

B. Basal lvs. not divided to near the base.

affinis, Gray (*Lithophragma affinis*, Gray). Sts. stout, 1–2 ft. high: lvs. radical, roundish in outline, crenately lobed, varying into the cauline; cauline mostly parted into 3 broad divisions, which are deeply incised or merely toothed: calyx turbinate; petals 3-lobed at the apex. Ore. to S. Calif.

BB. Basal lvs. divided to near the base.

parviflora, Hook. (*Lithophragma parviflora*, Nutt.). Height $\frac{3}{4}$ –1 ft.: radical lvs. mostly 3–5-parted or -divided, the divisions narrowly cuneate and once or twice 3-cleft into narrow lobes: fls. pink or sometimes white; petals with a slender claw, the limb palmately 3–7-parted. Brit. Col. to Utah and Colo.

T. rubrifolia, Hort., is offered in the trade abroad, as a plant growing 1 ft. high with beautiful foliage and very pretty fls. Probably it is *T. grandiflora* var. *rubra*. F. TRACY HUBBARD.†

TELOPEA (Greek, *seen at a distance*, of fanciful application). *Proteaceæ*. Tall shrubs, occasionally grown in the greenhouse and one species has been experimented with in S. Calif., but so far has not proved very successful. Lvs. alternate, entire or dentate: fls. showy, red, hermaphrodite, twin-pedicelled, densely racemose; racemes terminal, subglobose or ovoid; bracts exterior, membranaceous, colored; perianth-tube elongated, segms. at length more or less separated; disk fleshy, strongly oblique but almost perfectly annulate; ovary long-stipitate, many-ovuled: follicle stipitate, oblique, leathery, recurved.—Three species, 2 Australian, 1 Tasmanian. An earlier name of the genus is *Hylogyne*, but *Telopea* is included in the list of “nomina conservanda” accepted by the Vienna Congress.

speciosissima, R. Br. (*Embothrium speciosissimum*, Smith). **WARATAH.** **WARRATAU.** Stout glabrous shrub 6–8 ft. high: lvs. cuneate-oblong, 5–10 in. long, mostly toothed in the upper part, coriaceous: fls. crimson, in a dense ovoid or globular head 3 in. across: involueral bracts colored, the inner ones 2–3 in. long. New S. Wales. B.M. 1128. G.C. II. 17:677; III. 55:348. Gn. 22:400. I.H. 34:29.—One of the showiest shrubs of New S. Wales. The heads are 3 in. across and 3–4 in. deep and bear a rough resemblance to a florist's chrysanthemum. The showiest parts, however, are involueral bracts. This plant is known as waratah. It is one of the most distinct members of its family, for a horticultural account of which see *Protea*. Seeds of this species are imported into Calif. frequently, but although they germinate readily, the seedlings damp-off still more readily. Probably if the plant were once established it could be easily prop. by layering or by cuttings.

F. TRACY HUBBARD.†

TEMPLETONIA (J. Templeton, botanist of Belfast, early part of 19th century). *Leguminosæ*. CORAL BUSH. Shrubs or rarely subshrubs, cult. in the greenhouse abroad and hardy outdoors in the extreme S., where they may be used as ornamentals. Lvs. alternate, simple, entire or reduced to minute scales; stipules small or none: fls. red, yellow, or purple, axillary, solitary

3786. *Tephrosia macrantha*. ($\times \frac{1}{4}$)

or 2 or 3 together; calyx 5-lobed, lobes unequal; standard orbicular or obovate, usually reflexed; wings narrow; keel as long as the standard or shorter; stamens all united in a sheath open on the upper side; ovary sessile or stipitate: pod sessile or stipitate, much flattened, ovate-oblong or linear, completely dehiscent.—About 8 species, Austral. Said to do best in a mixture of sandy loam and peat. Prop. by cuttings.

retusa, R. Br. (*T. glauca*, Sims). CORAL BUSH. Tall glabrous or glaucous shrub: lvs. broadly obovate to narrow-cuneate-oblong, sometimes all under $\frac{3}{4}$ in., sometimes all over 1 in. long, emarginate or mucronate, coriaceous: fls. red (or rarely white); calyx with 4 very short, broad teeth, the lowest longest: pod $1\frac{1}{2}$ –2 in. long. B.M. 2088; 2334. B.R. 383; 859. L.B.C. 6:526; 7:644.—Cult. in S. Calif. where it blooms in the winter.

F. TRACY HUBBARD.†

TEOSINTE: *Euchlæna*.

TEPHRÛSIA (Greek, *tephros*, ash-colored, hoary; referring to the foliage). *Leguminosæ*. Hardy or half-hardy perennial herbs, subshrubs, or rarely shrubs, of little horticultural value.

Leaves uneven-pinnate; lfts. numerous, rarely 1–3, linear; stipules bristle-like or broader and striate: racemes terminal, opposite the lvs. or in the upper axils: fls. in fascicles of 2–6, red, purple, or white; calyx-lobes subequal or the 2 upper longer; petals clawed, standard suborbiculate, outside more or less silky-villous; wings obliquely obovate or oblong; keel incurved, obtuse or rather acute; ovary sessile, many-ovuled: pod linear, rarely ovate, compressed 2-valved.

—About 170 species, natives of the warmer regions of the world.

grandiflora, Pers. (*Galèga grandiflora*, Vahl). Rigid shrub 1–2 ft. high, pubescent or nearly glabrous: lvs. short-petioled; lfts. 5–7 pairs, cuneate-oblong or linear-oblong, variably pubescent on both surfaces: fls. fasciculate-corymbose, red, fulvous on the outside, 8–10 lines long: pod broad, linear, plano-compressed. S. Afr. B.R. 769.

virginiana, Pers. (*Cracca virginiana*, Linn.). GOAT'S RUE. CATGUT. WILD SWEET PEA. HOARY PEA. Silky-villous: st. erect, simple, 1–2 ft. high, leafy to the top: lfts. 17–29, linear-oblong: fls. large and numerous, clustered in a terminal, ellipsoid, dense raceme or panicle, yellowish white marked with purple. June, July. Dry sandy soil, southern N. H. to Minn. and southward.

macrantha, Rob. & Greenm. Fig. 3786. Shrub, 6–10 ft. tall: lvs. odd-pinnate; lfts. about 10–12 pairs, oblong-linear, entire, short-acute or cuspidate: fls. in loose terminal panicles 1 ft. long, shaded purple and white, nearly as large as sweet peas; standard very large, erect, oblong-orbicular. Mex. G.F. 7:175 (reduced in Fig. 3786).—A very showy plant, deserving of planting where hardy. Pringle writes that "for weeks it lights up the thickets of hillside ravines with masses of pleasing color." F. TRACY HUBBARD.†

TERMINALIA (alluding to the leaves being borne upon the terminus of the shoot). *Combretæcæ*. Only one species, *T. Catappa*, the Indian almond or tropical almond, is well known in American horticulture, but several others are important in the Orient, principally for their fruits, known as myrobalans, which are used in dyeing, tanning, and in medicine.

Leaves alternate, or rarely opposite, often crowded toward the ends of the branchlets, usually petiolate and entire: fls. sessile or nearly so, small, hermaphrodite or polygamo-diceious, usually in elongated spikes but sometimes in heads; calyx-tube ovoid or cylindrical, constricted above the ovary, the limb urn-shaped or campanulate, 5-toothed, usually deciduous; petals none; stamens 10, in 2 series, the 5 inferior opposite the calyx-teeth, the 5 superior longer, alternating with the teeth; filaments exerted, subulate or filiform; anthers small, the lobes scarcely connected; ovary unilocular, style subulate, often villous at base, stigma simple; ovules 2, rarely 3: fr. a drupe, ovoid, angular, compressed or 2–5-winged, 1-seeded, the cotyledons convolute.—A genus of about 100 species distributed throughout the tropics, principally in S. Asia, with only a few in Amer.

Catappa, Linn. TROPICAL ALMOND. INDIAN ALMOND. MYROBALAN. ALMENDRO. AMENDOEIRA. Fig. 3787. A tall, stately tree, up to 80 ft. high, with horizontal branches arising from the primary axis in whorls 3–6 ft. apart: bark smooth, brownish gray: lvs. clustered at the ends of the young branchlets, alternate, entire, obovate, obtuse to subacuminate at the apex, attenuate toward the slightly auricled base, 6–12 in. long, 3–6 in. broad, coriaceous, glabrous above, very finely pubescent below, venation slightly raised on both surfaces but most prominent below; petiole stout, under 1 in. long, flattened above, rusty-pubescent: fls. whitish, upper ones staminate and lower ones perfect, in finely pubescent spikes up to 6 in. long; calyx-segms. acute, slightly concave, valvate in bud, finely pubescent; filaments subulate, inserted upon the hairy disk; anthers cordate: fr. broadly oval in outline, elliptical and 2-

3787. Nut of tropical almond.—*Terminalia Catappa*. ($\times \frac{1}{4}$)

winged in transverse section, $1\frac{1}{2}$ -2 in. long, indehiscent, greenish or reddish, glabrous, with a firm, fleshy exocarp and a hard endocarp inclosing the oblong-elliptical seed; testa membranous, the cotyledons whitish, inrolled spirally. B.M. 3004.—Indigenous to beach forests of the Andaman Isl., but now cult. widely throughout the tropics; Schimper points out that the frs. are adapted for dispersal by ocean currents, the thick husk containing air-cells enabling them to float for a long time. The tropical almond (so-called, but not related to the true almond) is extensively planted in S. Fla., the W. Indies, Cent. and S. Amer., as a street and ornamental tree. Its greatest disadvantage seems to be that it is deciduous during the cold season (shedding its lvs. twice a year in Ceylon, according to Macmillan), but the rich reddish hues assumed by the foliage before falling make it very attractive. There are many fine avenues planted to it throughout the tropics. The nut seems to be much less esteemed in Amer. than in the Orient. Firminger describes it as "of a fine filbert-like flavor, with a crispness like that of a fresh walnut; beyond comparison the most delicious of any kind of nut the country (India) affords." He also states that the kernels, when removed from the husk, are generally served on the table in a plate of water. They yield a valuable oil, resembling almond oil, which is used in India. The tasar silkworm is fed on the lvs., according to Watt. In S. Fla. this is one of the most popular ornamental trees for street and avenue planting. It is not grown in Calif., and is probably too tender for most locations in that state. Prop. seems to be exclusively by seed.

T. Arjuna, Bedd., a large tree indigenous to Cent. and S. India, and cult. in other parts of the country, has recently been intro. to the U. S. and is doing finely in S. Fla. The bark is sometimes used in dyeing and tanning, according to Watt, and also in native medicine. —*T. australis*, Cambess., Brazil and Argentina, has been intro. in S. Calif.: described as a medium-sized and very rapid-growing tree of symmetrical shape, suitable for street planting: lvs. small for the genus, lanceolate, acute or obtuse, shining above: fls. in roundish congested long-peduncled heads; drupe glabrous, ovate-lanceolate, beaked, with plicate margin. —*T. Bellerica*, Roxbg., the beleric myrobalan, a large tree found throughout the forests of India, Burma, and other parts of S. Asia, yields a fr. which is exported from India for use in tanning. The kernels are eaten in India, but are said by Watt to cause intoxication if taken in excess. —*T. Benzoi*, Pers., properly *T. angustifolia*, Jacq., has recently been intro. to S. Fla., and promises to succeed. It is a handsome tree with narrow lvs., indigenous to Malaya. —Under the name of *T. edulis*, Blanco, a plant has recently been intro. to the U. S. from the Philippines which is probably *T. Bellerica*. It is doing well in S. Fla. and promises to be an unusually handsome ornamental. Barrett says of it "this magnificent large forest tree occurs, not very commonly, in the provinces of Bataan and Cavite (Philippines). In the rainy season abundant crops of cherry-like frs., about 2-3 cm. in diam., are produced. Each fr. contains 1 seed surrounded by sweet pulp somewhat resembling that of the duhat (*Eugenia jambolana*) in flavor. The pulp with the addition of lemon or some other acid juice makes a beautifully colored jelly." The tree is known as "calompit" in the Philippines.

F. W. POPEOE.

TERNSTRØMIA (named for Christopher Ternstrøm, Swedish naturalist; died 1745). *Ternstræmiaceæ*. Evergreen trees or shrubs, adapted to the warm-house. Lvs. leathery, entire or serrate-crenate; peduncles 1-fld., recurved, axillary or lateral, solitary or somewhat fascicled, 2 bracteoles below the fl.: sepals 5; petals 5; stamens numerous; ovary 2-3-celled (sometimes imperfectly so); fr. indehiscent.—About 45 species, warmer Asia, Indian Archipelago and Trop. Amer.

japonica, Thunb. (*Cleyera japonica*, Thunb., not Sieb. & Zucc. See *Cleyera*.). Small tree or shrub, 10-12 ft.: lvs. alternate, short-stalked, entire, obovate-oblong or oblong, glabrous, feather-veined: fls. clustered: berries about the size of peas. Japan. S.Z. 1:81.

TESTUDINÀRIA (from *testudo* a tortoise, alluding to the supposed resemblance to a tortoise of the above-ground roots). *Dioscoriaceæ*. The HOTTENTOT'S BREAD, TORTOISE PLANT, or ELEPHANT'S FOOT. Perennial plants bearing a slender twining vine from a large

hemispherical rhizome or caudex which is above ground and solid-fleshy or woody; sometimes grown in the greenhouse as curiosities or for illustration to students of botany, but not in common cultivation.

Stems twining, slender, herbaceous: lvs. alternate, caudate or somewhat deltoid: fls. dioecious, small, racemose at the axils; perianth of male fls. broad-campulate, 6-cleft, stamens 6, styles rudimentary; perianth-segms. of female fls. small, staminodia small; ovary ovoid or oblong, 3-celled: caps. 3-angled, angles prominent, cuneate-wing-like.—Three species from S. Afr.; a fourth has been described from Mex.

elephantipes, Salisb. Rootstock studded with angular woody protuberances, sometimes 1-3 ft. diam.: sts. slender, glabrous, much branched, twining, 8-10 ft. high: lvs. suborbicular, bright green or glaucous, mucronate: fls. small, inconspicuous, the racemes greenish yellow or whitish. S. Afr. B.M. 1347 (as *Tamus*. B.R. 921.—The globular yam-like bulb or rootstock sometimes weighs 100 pounds. The inner part of this "bulb" has been compared to a turnip for texture and color. The Hottentots used to cut it in pieces, bake it in the embers and eat it. Old and grotesque bulbs have been brought from time to time from the Cape as curiosities. The plant is of easy cult. in a cool greenhouse. No method of prop. by the bulb is known.

paniculata, DuRoi. Rootstock above ground, about 3 in. high, irregularly oblong, woody, flattened above, tessellately lobed, fuscous: sts. twining above, rigid, glabrous, greenish: lvs. $1-3 \times 1\frac{1}{2}-4\frac{1}{2}$ in., broadly reniform or shortly deltoid-subcordate, obsoletely 3-lobed, mucronate, petioled: panicles axillary, many-fld., sparsely or much branched: fls. pedicelled, odorous, rather greenish or pale yellowish. S. Afr.

F. TRACY HUBBARD.†

TETRACÉTRON (Greek, *four* and *spur*, referring to the 4 spur-like appendages of the fr.). *Magnoliaceæ*. A deciduous tree from China with alternate petioled ovate lvs. palmately 5-7-veined, serrate, exstipulate: fls. sessile, small, perfect, in slender pendulous racemes, apetalous; sepals 4, ovate, imbricate; stamens 4, inserted before the sepals, exserted; carpels 4, connate along the ventral suture; styles 4, recurved; ovules pendulous, several in each cell: fr. a 4-celled deeply lobed caps., loculicidally dehiscent; seeds linear-oblong. Next to *Cercidiphyllum* this is the tallest deciduous tree of China, attaining occasionally to 100 ft., and 20 ft. in girth. In its foliage it bears a strong resemblance to *Cercidiphyllum*, though not closely related, but it is easily distinguished by the alternate lvs., solitary, not in 2's on the spurs. It has proved hardy at the Arnold Arboretum, at least in sheltered positions, but does not seem to grow so well as *Cercidiphyllum*, with which it probably shares the same exigencies as to cult. and prop. *T. sinense*, Oliver. Tall tree with smooth pale or rufous gray bark: lvs. slender-petioled, ovate or elliptic-ovate, acuminate, cordate at the base, bluntly serrate, 3-5 in. long: racemes $2\frac{1}{2}-4$ in. long, short-stalked, slender; fls. yellowish, minute; the exserted stamens about 1 line long: caps. brown, $\frac{1}{2}$ in. long. June, July. Cent. and W. China. H.I. 19:1892.—The tree needs to be further tested in this country.

ALFRED REHDER.

TETRADYMYIA (*four together*, from Greek words, referring to the 4-fld. heads of one species). *Compositæ*. A genus of low rigid shrubs of the composite family native to the arid regions of W. N. Amer. Herbage covered with dense matted wool: lvs. alternate, often modified into spines. The original species, *T. canescens*, is the best known. Its heads have only 4 fls. They are yellow and about $\frac{1}{2}-\frac{3}{4}$ in. long. This plant was offered in the E. in 1881 by western collectors but has no horticultural standing and is now probably not in cult. in Amer. There are about a half-dozen species, but not known horticulturally.

TETRAGONIA (Greek, *four-angled*, referring to the usually four-angled fruit). *Aizoaceae*. Here is included a garden vegetable of minor importance.

Herbs or subshrubs from the southern hemisphere and Japan; usually decumbent: lvs. alternate, short-petioled, somewhat fleshy: fls. yellow, green, or reddish, axillary, apetalous; calyx 3-5-lobed.—Only 1 species in cult., but 20 or more species are known in E. Asia and the southern hemisphere.

expansa, Thunb. **NEW ZEALAND SPINACH**. **NEW ZEALAND ICE-PLANT**. Fig. 3788. A hardy or half-hardy annual 4-8 in. high, often spreading 4-6 ft.: lvs. triangular, larger ones 4-5 in. long by 2-3 in. broad: fls. small, yellowish green. New Zeal. B.M. 2362.

New Zealand spinach is chiefly useful for furnishing greens during the summer when the common spinach cannot be grown. It tastes something like spinach but is somewhat tougher, as a rule. It is grown to some

3788. *Tetragonia expansa*. ($\times \frac{1}{2}$)

extent in California both for man and sheep. It readily self-sows. For an early outdoor crop, fresh seed should be sown in rich soil in a warm room in January or early February. The seed may germinate in a week or ten days but frequently requires a month to start. After growing about two weeks the seedlings should be transplanted to thumb-pots and about a month later to 4-inch pots. Growing vigorously in this condition they will be good-sized plants to move into the garden toward the end of April, where they should be set 3 to 4 feet apart each way, and the plants, when grown, will entirely cover the ground. They should be handled with great care in transplanting, otherwise growth will be so checked that it will require several weeks to recuperate. Again, plants should never be allowed to become pot-bound, as this will immediately bring them into flower and fruit and stunt their further growth, as well as greatly shorten their period of productiveness. Well-grown plants should be ready for use by June 1 and, if vigorous growth continues, nearly a peck of greens can be gathered from each plant once a week until heavy autumn frosts. In gathering, only 4 or 5 inches of the tip ends of the larger plants should be taken. In the South, it is usually dwarf, not generally

exceeding 6 to 8 inches. There is another and somewhat easier method of growing the crop, although a given area will be less productive. Inasmuch as the plant is a hardy annual, many seeds which ripen late in autumn will fall to the ground and germinate early in spring, though not early enough for the plants to be injured by spring frosts. These will be large enough for use toward the end of June. Annual crops are thus grown on the same ground several successive seasons with no care except removing old plants and keeping the ground free from weeds.

For the forcing-house crop, seed should be sown during July in seed-beds where the plants remain until the latter part of September, when they should be taken directly to the benches and will be ready for use early in November. It is best to set the plants about 18 inches apart in benches at least 6 inches deep. No further attention is necessary except to give plenty of water, and under good conditions a peck of greens will be produced once a week on 4 square feet from November to May inclusive. A crop may also be grown beneath the benches near the walks, as well as in the grapery borders. Space that cannot be used for other purposes may thus be utilized to very good advantage, although the plants will not produce so abundantly.

This crop may also be grown in houses with portable roofs by starting the plants in summer in houses with the roofs removed, the roofs being replaced on the approach of cold weather. The plants will continue producing the entire winter and following spring, when they should be uncovered and will reproduce themselves in the same way as the summer crop.

H. C. IRISH.

TETRAGONÓLOBUS: *Lotus*. The following species now in cult. was not treated in Vol. IV, p. 1917. **Lótus siliquódus**, Linn. (*Tetragonólobus siliquódus*, Roth). Perennial, trailing, hirsute: rhizome slender, branched: sts. ascending: lvs. oblong or obovate; petioles with the stipules shortly adnate: peduncles 1-fld., much longer than the fl.: fls. pale yellow; calyx-segms. lanceolate: pod with straight wings much narrower than the body. *Medit. region.*

TETRAMICRA: *Leptotes*.

TETRANÈMA (Greek, *four and filament*; the genus is characterized by having 4 stamens). *Scrophulariaceae*. Perennial herbs, grown in the greenhouse. St. very short or in cult. slightly elongated, ascending: lvs. nearly radical, opposite, obovate or oblong, slightly crenate-dentate, base angulate, glabrous: peduncles axillary, scape-like, longer than the lvs., bearing an umbel-like cyme at the top: fls. short-pedicelled, nodding, purple-violet, variegated paler; calyx 5-parted; corolla declinate, posterior lip shortly 2-lobed, anterior larger, 3-cleft; stamens 4: caps. rather compressed, loculicidally dehiscent.—Two species, Mex. and Guatemala. **T. mexicanum**, Benth., is the only species cult., known as the "Mexican foxglove" and formerly as *Pentstemon mexicanus*. The pretty fls. are borne in profusion on the summits of slender purple scapes 6-8 in. high. Although essentially a summer bloomer, with good care it may be made to flower most of the year. It is usually regarded as a warmhouse subject, but it makes a good window-plant and is easy to grow. Plants continue to bloom year after year. Prop. by seeds. B.M. 4070. B.R. 29:52. H.U. 6, p. 71.

F. TRACY HUBBARD.†

TETRÁPANAX (*four and panax*, referring to the four-merous flower structure). *Araliaceae*. By Bentham & Hooker (*Genera Plantarum*) this genus is included in *Fatsia*, and is so treated in Vol. III, page 1204. By others, however, it is kept distinct, and the plant known as *Fatsia papyrifera* then becomes **T. papyríferum**, Koch, the only species. The reader may take his choice whether to name the plant in one genus or the other;

the preference probably lies with placing it in *Tetrapanax*. This genus, if accepted, differs from *Fatsia* in its four-merous rather than mostly five-merous flowers, with two-merous ovary, the tomentose-lanate character, and other features. *T. papyrifera* is an excellent subtropical subject.

Fatsia japonica, Decne. & Planch., remains in that genus, as treated on page 1204.

TETRASTIGMA (Greek, *four* and *stigma*, in reference to the 4-lobed or 4-parted stigma). *Vitaceæ*. About 40 species in Trop. and Subtrop. Asia of shrubs climbing by tendrils: lvs. alternate, digitate or pedate; lfts. 3-5, sometimes reduced to 1; tendrils with adhesive disks or twining: fls. polygamo-dioecious, in axillary cymes or umbels, 4-merous; petals spreading; disk adnate to the base of the ovary; stigma sessile, 4-lobed or 4-parted; berry 2-4-seeded; seeds ovoid-globose, sulcate on the inner surface. Allied to *Cissus* and *Parthenocissus* but easily distinguished by the sessile 4-lobed stigma and from the latter by the 4-merous fls. Of the numerous species only the following are occasionally cult.; *T. obtectum* and *T. serrulatum* are probably the hardiest, but tender in the N., and are graceful small-lyd. vines which may be used where vines of more delicate character are desired; the first species clings to walls, the second has twining tendrils. *T. Harmandii* is a tall-growing vine with larger lvs. and edible berries, suited only for tropical or subtropical countries. For cult. and prop., see *Cissus* and *Parthenocissus*. *T. obtectum*, Planch. (*Cissus obtecta*, Wall.). Climbing with disciferous tendrils: branchlets hirsute: lvs. long-stalked, persistent or subsistent; petioles pubescent; lfts. 5, digitate, sessile, cuneate-obovate to elliptic, acute, remotely crenate-serrate with mucronate teeth, glabrous, or in var. *pilosum*, Gagnep., pubescent beneath, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long: fls. greenish, in slender-stalked umbels; pedicels slender: berries ovoid, $\frac{1}{4}$ in. long. Himalayas, Cent. and W. China. *T. serrulatum*, Planch. (*Cissus serrulata*, Roxbg. *Vitis capreolata*, Don). Climbing with twining tendrils, glabrous: lfts. 5, pedate, sometimes 3, short-stalked, ovate or elliptic to elliptic-lanceolate, acute or acuminate, serrate, $\frac{1}{2}$ -2 $\frac{1}{2}$ in. long: fls. in compound cymes: fr. globose, black, $\frac{1}{4}$ in. thick or slightly larger. Himalayas, W. China. *T. Harmandii*, Planch. High climbing with twining tendrils: lfts. 3-5, short-stalked, narrowly lanceolate, serrate, glabrous, about 2-3 in. long: fls. in axillary short-stalked cymes: fr. globose, 2-3-seeded. Philippine Isls. Recently intro. by the Dept. of Agric.; said to have edible berries similar to those of the Scuppernong grape.

ALFRED REHDER.

TETRATHECA (Greek, *four* and *cell*; the anthers are sometimes four-celled). *Tremandraceæ*. Slender glabrous or stellate-pubescent, heath-like little shrubs, grown in the greenhouse and out-of-doors in the far South.

Leaves alternate, verticillate or scattered, heath-like, entire, flat and toothed or reduced to minute scales: fls. 4-5-merous; stamens apparently in a single series; disk inconspicuous: caps. opening only at the edges.—About 20 species, all from Austral. In European greenhouses all the plants of this family are considered difficult of cult. They are treated like many other Australian heath-like plants, being potted in fibrous peat and silver sand and watered carefully at all times. It is said that only soft rain-water should be used.

A. *Sts. terete*, leafy.

B. *Lvs. mostly verticillate*.

thymifolia, Smith. Lvs. almost all verticillate in 3's or 4's, ovate-elliptical or lanceolate: fls. purple; sepals ovate-lanceolate, acute or acuminate, seldom reflexed; ovary glabrous or more frequently pubescent, with 2 superposed ovules. B.M. 8028.

ericifolia, Smith. Subshrub 1 ft. or less high, branched, rough-pubescent or nearly glabrous, rarely hirsute: lvs. mostly verticillate, narrow-linear, margins closely revolute, rarely oblong-lanceolate and more open: fls. pink, on slender pedicels; sepals ovate, obtuse, not reflexed; ovary glabrous or rarely pubescent with 2 superposed ovules: caps. obovate-cuneate. R.B. 28:121.

BB. *Lvs. rarely somewhat verticillate*.

pilosa, Labill. Much branched, glabrous or hispid, about 1-1 $\frac{1}{2}$ ft. high: lvs. usually linear, margins much revolute, 4-6 lines long: fls. purple, rather small; sepals ovate, obtuse or acute; petals narrow; ovary glabrous or pubescent, 1-ovuled: caps., obovate. F.S. 10:1065 (as *T. ericoides*). Gn.W. 20:361.

AA. *Sts. very angular or flat, almost leafless*.

hirsuta, Lindl. *Sts.* rather rigid and erect, 6-18 in. high, minutely pubescent and often hispid with few long spreading reddish hairs: lvs. mostly alternate, ovate-lanceolate to oblong-linear, obtuse, all less than $\frac{1}{2}$ in. long: fls. rather large, pink, on slender pedicels; sepals lanceolate; petals oblong, ovary glabrous or slightly glandular, with 1 ovule in each cell. B.R. 30:67. J.H. III. 42:461. F. TRACY HUBBARD.

TEUCRIUM (Teucer was the first king of Troy). *Labiataë*. GERMANDER. Herbs, subshrubs, or shrubs, some of which are greenhouse plants or outdoors in the extreme South, others of them hardy in the North and suitable for the wild-garden or rockwork.

Leaves entire, dentate or incised, sometimes many-cleft; floral lvs. similar or reduced to bracts: floral whorls 2-fld., rarely many-fld., arranged in racemose spikes or terminal heads, rarely with the fls. in a terminal spike or irregularly whorled; calyx tubular or campanulate, rarely inflated, 10-nerved, 5-toothed; corolla-tube included or rarely exserted, limb as if 1-lipped, lower lip large, upper very small or split so as to appear to be wanting; stamens 4, in 2 pairs, exserted through the split notch in the short upper lip: nutlets obovoid, reticulate, rugose.—About 160 species, widely distributed through the warmer and temperate regions of the world. Monographed by Bentham in De Candolle's *Prodromus Systematis Naturalis*, Vol. 12 (1848). The specific descriptions in the present article are largely based on this work but the sequence of sections and species is according to Briquet in Engler and Prantl, *Pflanzenfamilien* VI. 3a.

The *teucriums* are little known in cultivation. They probably present no special difficulties to the gardener.

- EE. Species hoary shrubs..... 12. betonicum**

Section I. POLIUM.

1. montanum, Linn. Low subshrub, prostrate, hoary or pubescent: sts. much branched at base, summit shortly ascending or rarely suberect and 2-4 in. high: lvs. oblong-linear, entire, base narrowed to a very short petiole, beneath or both surfaces hoary: floral whorls few, condensed into a terminal head, which is hemispherical: fls. white becoming yellow; calyx tubular-campanulate, glabrous or hoary, teeth lanceolate, subulate-acuminate. S. Eu. and Orient.

2. Polium, Linn. Low canescent-tomentose, lanate or rarely pilose-hispid shrubs, 2-6, rarely 12 in. high: basal branches procumbent, ascending or rarely suberect: lvs. cuneate-oblong or linear, sessile, crenate, margin revolute, upper surface very short-tomentose, densely lanate or pilose, color, especially above, yellowish hoary, golden or rarely green; floral lvs. similar: floral whorls few, 2-6-fld., condensed in a globose or oblong head, which is solitary or often several corymbosely glomerate: fls. white, yellow, or purple; calyx tubular-campanulate; corolla small. Medit. region and Orient.—A decidedly variable species. Var. *flavescens*, Benth. (*T. aureum*, Schreb.), has broader lvs., very hairy heads and yellow tips to the branches.

3. pyrenæicum, Linn. Perennial, repent or diffusely much branched, villous, sterile branches whip-like, fertile short-ascending: lvs. petioled, rotundate, 4-8 lines diam., crenate, base truncate, rounded or cuneate, both surfaces green and hirsute, especially near the margins and nerves; floral lvs. petioled, oblong-linear, entire, acute: floral whorls few, condensed in a small terminal head: fls. yellow (or white); calyx campanulate, teeth acuminate-acute; corolla-lobes often purplish at base. Mountains of S. W. Eu.

Section II. CHAMÆDRYS.

4. Chamædryas, Linn. Perennial or shrubby, 1-2 ft. high, base decumbent, branching, pubescent or villous: lvs. short-petioled, ovate or oblong, incised-crenate, base cuneate, both surfaces green or canescent beneath; floral lvs. smaller and dentate: floral whorls 2-6-fld., the upper racemose: fls. red-purple or bright rose, with red and white spots, $\frac{3}{4}$ in. long, rather showy; calyx tubular-campanulate, teeth lanceolate, acuminate. Eu.—A good border plant for late summer bloom.

5. Marum, Linn. Shrub, low, very much branched, and hoary: lvs. small, ovate, 2-4 lines long, short-petioled, entire or very rarely crenate, hoary beneath; floral lvs. smaller: floral whorls 2-4-fld., racemose, subsecund, raceme 1-2 in. long, whorls approximate: fls. purplish; calyx hirsute, tubular-campanulate; corolla villous outside. Medit. region.—A low greenhouse shrubby plant similar in habit to *Thymus vulgaris*.

Section III. SCORODONIA.

6. Scorodonia, Linn. Erect, hispid perennial, 1-2 ft. high, pubescent or subglabrous: lvs. ovate, 1-2 in.

long, obtusely crenate, short-petioled, base rounded or cordate, both surfaces green; floral lvs. minute: raceme somewhat branched, rather paniculate above: fls. yellow; calyx rather villous, broadly campanulate; corolla-tube exerted, pubescent outside, the tube twice as long as the calyx. Eu. and adventitious in E. N. Amer.

Section IV. STACHYBOTHYS.

7. canadense, Linn. Erect, perennial herb, 1-3 ft. high, soft-pubescent or canescent: lvs. ovate-lanceolate to oblong-ovate, 2-3 in. long, serrate, base rounded, somewhat canescent beneath, short-petioled; floral lvs. bract-like, sessile, lanceolate: spikes 2-6 in. long, rather lax, simple: fls. purple to cream-color; calyx short-pedicelled, campanulate, hoary and somewhat villous; corolla-lip elongated. Low ground, Maine to Brit. Col., southward to Pa., Ohio, Mo., New Mex., and Calif.—Useful for low grounds and moist borders.

8. hircanicum, Linn.; also spelled *hyrcanicum*. Erect perennial herb 1-2 ft. high, slightly branched, pubescent: lvs. ovate-cordate, 1-3 in. long, obtuse, coarsely crenate, base deeply cordate, scarcely pubescent above, softly somewhat canescent beneath; floral lvs. as subulate bracts: spike simple, 3-8 in. long, dense: fls. purple or red; calyx 2-lipped; corolla villous outside. Caucasus and Persia.

Section V. TEUCRIS.

9. bicolor, Smith. Dwarf, herbaceous, glabrous: lvs. ovate, oblong or lanceolate, about 1 in. long, obtuse, entire or incised, both surfaces green; floral lvs. usually exceeding the fls.: peduncles axillary, 1-fld., short, upper subracemose: fls. blue and white; calyx broadly campanulate, green, teeth broad-lanceolate, acute; corolla-tube included. Peru and Chile.—Offered in Calif. at one time, but apparently not successful.

10. orientalis, Linn. Erect perennial herb, about 1 ft. high, branched at base, green and glabrous or pubescent, canescent: lvs. 1-2-pinnatisect, lower $1\frac{1}{2}$ -2 in. long, segms. linear, entire or incised, both surfaces pale or green; upper lvs. smaller; floral lvs. minute: peduncles laxly racemose, irregularly 1-3-fld.; pedicels much longer than floral lvs.: fls. violet or blue; calyx campanulate, teeth lanceolate; corolla 3 times longer than calyx. Caucasus and Asia Minor.

11. fruticans, Linn. Shrub 2-3 ft. high, divaricate branching: lvs. ovate, entire, obtuse, glabrous above, white or reddish brown, tomentose beneath, petioled; floral lvs. similar, smaller: racemes terminal or lateral on short branches, few-fld.; peduncles 1-fld., shorter than the calyx: fls. blue; calyx campanulate, tomentose; corolla-lip twice longer than the calyx. Eu.—Recommended for dry places S. It has a long blooming season.

Section VI. TEUCRIOPSIS.

12. betonicum, L'Her. Shrub 2-3 ft. high: branches hoary-tomentose: lvs. ovate-oblong, 1-1 $\frac{1}{2}$ in. long, rather long-petioled, hoary beneath or on both sides; floral lvs. usually lanceolate: floral whorls 2-fld., second, laxly racemose, raceme 3-6 in. long: fls. purple; calyx campanulate; corolla-tube somewhat exerted, pubescent outside, upper lobes of limb forming an obsolete upper lip, lateral lobes small, oblong, lowest oblong, concave. Madeira. R.H. 1912, p. 465.

T. frutescens, Hort., is offered in the trade as a shrub for the rockery, with downy foliage and heads of pale blue fls.; not known botanically; possibly it is an error for *T. fruticans*.

F. TRACY HUBBARD.

TEYSMANNIA (named for J. E. Teysmann). *Pal-maceæ*. Low unarmed palm, grown in the greenhouse: caudex underground: lvs. erect, elongate-rhomboid obtuse, base acute, margin lacinate, divisions 2-cleft: spadix rather short, branches divided at base, reflexed above; spathes papery-leathery: fls. hermaphrodite,

minute; calyx cup-shaped, 3-toothed; petals thick; stamens 6; ovary of 3 carpels, rarely 1 or 2, free or slightly coherent: fr. globose or depressed-globose, 1-celled, 1-seeded. One species, Sumatra. *T. altifrons*, Reichb. f. & Zoll. Lvs. 6-7 x 1½ ft., folded; petioles carinate dorsally, obsoletely concave in front, the angles rounded and uncinately-prickly: spathes sheathing the tomentose peduncle: fr. as large as an apple. Sumatra.

THALIA (named after Johann Thalius, a German naturalist; died 1588). *Marantiaceae*. Perennial marsh or aquatic herbs, some of them hardy, others suitable for the warm- or greenhouse.

Leaves few, large, long-petioled, often canna-like: panicles terminal; fls. in pairs along the branches forming lax spikes, the pairs in a 2-valved spathe; sepals 3, free, equal, membranaceous; petals 3, free or very shortly connate; lobes of the androecium petaloid, very irregular; lip broad, crested within; anthers 1-celled; ovary 1-celled, 1-ovuled, stigma 2-lipped: caps. oblong-ovoid or globose.—Schumann (Das Pflanzenreich, hft. 11) accepts 7 species, in Trop. and warm Temp. America.

A. Plant covered with a white powder.

dealbata, Fras. Stemless: petioles 1-2 ft. long: lvs. canna-like, cordate, ovate, 6-9 in. long: scape terete, 3-5 ft. high: panicles erect: spikes erect. June-Sept. Ponds and marshes, S. C. and west. B.M. 1690. G.W. 3, p. 620. B.B. 1:455.—A stately aquatic; should be placed in shallow water or in wet soil.

AA. Plant not powdery.

geniculata, Linn. (*T. divaricata*, Chapm.). Stemless: petioles longer than in *T. dealbata*: lvs. banana-like, 1-3 ft. long, oblong-ovate: scape 5-10 ft. high: panicles 2-4 ft. wide: spikes zigzag, pendulous. Sept., Oct. Ponds, Fla.—This native ornamental-lyd. marsh-plant thrives in garden soil with cannas and like plants. Does well under cultivation in S. Calif.

T. sanguinea, Lem. = *Stromanthe sanguinea*.

F. TRACY HUBBARD.†

THALICTRUM (ancient name of doubtful origin; perhaps ultimately from Greek *thallo*, to grow green). *Ranunculaceae*. MEADOW RUE. Interesting plants for the herbaceous border and wild-garden, with fern-like foliage and small flowers in panicles or terminal clusters.

Erect perennial herbs: lvs. ternately compound and decomposed; st.-lvs. alternate: fls. dioecious, polygamous, or perfect in some species, rather small, generally

greenish white or sometimes purple or yellow, borne in a panicle or loose raceme; sepals 4 or 5, deciduous; petals wanting; stamens many, showy: carpels usually few, 1-seeded. A monograph of the entire genus was published in 1885, by Lecoyer, in Bull. Soc. Roy. de Bot. de Belge, where he describes 69 species. In 1886 Trelease published a treatment of "North American Species of *Thalictrum*" in Proc. Soc. Bost. Nat. Hist. 23:293-304, in which he

recognized 11 species and 4 varieties north of Mex. His treatment is rather closely followed by Robinson in Gray's Syn. Flora, 1895. All N. American forms were treated by K. C. Davis in Minn. Bot. Studies, Aug., 1900. See also recent studies by E. L. Greene. About 80-90 species are now known, widely distributed in temperate regions, a few in the tropics.

Many *thalictrums* are very hardy, and only the more southern forms of those given below are at all tender. These plants are valued for their feathery heads of flowers, contrasting with their handsome stems and leaves, which are often of a purple cast. They are neat and attractive subjects, often conspicuous in the wild but not so much planted as they deserve. The spring-flowering species are mostly inhabitants of woods and groves, and the summer-flowering of low open grounds and swales, but they do well under garden conditions. The early ones are small and delicate plants, and the late ones are tall and often commanding. The tassel-like staminate inflorescence of some species is very attractive. *Thalictrums* may be propagated by seed, or by division of roots in early spring just as growth begins. The division of the roots is more popular than the seed method, as it produces strong plants much earlier. Seed is scarce in some species. Any good loamy soil will suit them, if well drained.

INDEX.

adiantifolium, 8.	dioicum, 18.	polygamum, 15.
adiantoides, 8.	dipterocephalum, 2.	Purdomii, 9.
alpinum, 7.	Fendleri, 14.	purpurascens, 16.
aquilegifolium, 1.	flavum, 10.	purpureum, 8.
Chelidonii, 3.	glaucom, 11.	saxatile, 8.
confine, 17.	minus, 8.	sparsiflorum, 6.
Cornuti, 1, 15.	occidentale, 13.	speciosum, 11.
dasycephalum, 16.	petaloideum, 5.	venulosum, 17.
Delavayi, 4.	polycarpum, 12.	

A. Fr. strongly angled and 2-3-winged, usually stipitate.

1. **aquilegifolium**, Linn. FEATHERED COLUMBINE. Fig. 3789. Sts. large, hollow, 1-3 ft. high, glaucous: lvs. once or twice 3-5-parted; lfts. stalked or the lateral ones nearly sessile, slightly lobed or obtusely toothed, smooth, suborbicular: fls. in a corymbose panicle, dioecious; sepals white; stamens purple or white: fr. 3-angled, winged at the angles. May-July. Eu., N. Asia. B.M. 1818; 2025 (as var. *formosum*). Gn. 47, p. 357; 50, p. 117. A.F. 16:1234. J.H. III. 50:203. Gn.W. 23:676 (var. *atropurpureum*). G.L. 23:249 (var. *atropurpureum*). G. 32:623 (var. *album*). G.C. III. 47:211 (var. *album*).—A good garden plant and frequently planted; fls. in early summer. The old name *T. Cornuti*, Linn., may be a synonym of this, and if so it is the older name, being published on a preceding page, but *T. Cornuti* was described as an American plant, while *T. aquilegifolium* is not. As the description and old figure of *T. Cornuti* do not agree with any American plant, the name may well be dropped. Plants advertised as *T. Cornuti* are probably *T. aquilegifolium* or *T. polygamum*.

2. **dipterocephalum**, Franch. Very smooth, rhizome short: st. simple, 2 ft. or more high, angled above: lower and middle lvs. broadly triangular, 4-6 in. broad, thrice ternately cut; lfts. subrotund, base slightly cordate, pale greenish above, glaucous beneath; cauline lvs. much smaller: panicle narrowly pyramidal: fls. rose, rather large; sepals ovate-lanceolate, long-acuminate: achenes subsessile, compressed, obovate, perceptibly inequilateral, marked on the faces with 3 fuscous nerves, each side rather broadly winged; wings membranaceous, white. Yunnan, China. G.C. III. 45: suppl. Aug. 3. G. 33:111; 36:277. G.M. 51:661. Gn. 72, p. 435. J.H. III. 64:95.—An excellent plant, much noticed abroad.

3. **Chelidonii**, DC. Dwarf and much branched: lvs. biternate, glaucous beneath and pale green above; lfts. about 1 in. across, orbicular-cordate, crenate or lobed: fls. 1 in. across, lilac or purple, in a rigid-branched panicle, the pedicels deflexing in fr.; sepals elliptic and

3789. *Thalictrum aquilegifolium*. (×¼)

obtuse; achenes many, long-stalked, reticulate, with an incurved style. Himalayas, 8,000–12,000 ft. G.C. III. 28:167.—A handsome plant.

4. *Delavayi*, Franch. Slender, 2–3 ft. high, glabrous: lower lvs. on long, slender petioles, 2–3 times 3–5-parted; lfts. long-stalked, 3–5-lobed, base cuneate, rounded or cordate; fls. pendulous, dioecious; sepals purple or lilac, $\frac{1}{2}$ in. long, equaling the slender stamens; anthers linear: carpels 10–12: fr. winged at the 3 angles, stipitate. Summer. Mountains of E. China. B.M. 7152. G.C. III. 8:125; 38:450. G. 35:793.

AA. Fr. striate edged or ribbed rather than winged, sessile or essentially so in most species.

B. Fls. probably perfect.

c. Filaments widened near the anthers, the latter ovate and obtuse.

D. Achenes sessile in a head, ovate-oblong.

5. *petaloideum*, Linn. St. round, nearly 1 ft. high, almost naked: lvs. 3–5-parted; lfts. smooth, ovate, entire or 3-lobed; fls. corymbose, perfect; sepals white, rotund; filaments pink; anthers yellow: fr. ovate-oblong, striated, sessile. June, July. N. Asia. L.B.C. 9:891. G. 28:625.

DD. Achenes somewhat stalked, widely spreading, straight on the dorsal margin.

6. *sparsiflorum*, Turcz. St. erect, sulcate, 2–4 ft. high, branching, usually glabrous: lvs. triternate, upper ones sessile; lfts. short-stalked, round or ovate, variable in size and shape of base, round-lobed or toothed: fls. in leafy panicles on slender pedicels, perfect; sepals obovate, whitish, soon reflexed; filaments somewhat widened; anthers very short: achenes short-stalked, obliquely obovate, flattened, dorsal margin straight, 8–10-nerved; styles persistent. N. Asia, through Alaska to Hudson Bay, in mountains to Colo. and Calif.

CC. Filaments filiform or at least very slender; anthers linear, acute or mucronate.

D. Stigma hastate or spurred.

7. *alpinum*, Linn. Sts. smooth, naked or 1-lvd., only 4–8 in. high, from a scaly rootstock: lvs. tufted at the base, twice 3–5-parted; lfts. coriaceous, orbicular or cuneate at the base, lobed, revolute: fls. in a raceme, perfect; sepals greenish, equaling the yellow stamens; stigma linear: achenes small, obliquely obovoid. Northern and Arctic, and alpine regions of both Old and New Worlds. B.M. 2237.

DD. Stigma not hastate or spurred.

8. *minus*, Linn. (*T. purpureum*, Schang. *T. saxatile*, Vill.). Sts. round, sulcate, 1–2 ft. high: lfts. variable, acute or obtusely lobed, often glaucous: fls. drooping, in loose panicles, perfect; sepals yellow or greenish: fr. ovate-oblong, sessile, striated. Summer. Eu., Asia, N. Afr.—A polymorphous species in the variation of the lfts.

Var. *adiantifolium*, Hort. (*T. adiantoides*, Hort. *T. adianthifolium*, Bess.). Lfts. resembling those of *adiantum* fern.—A form much used and admired.

9. *Purdomii*, J. J. Clark. Much like *T. minus*, but fls. larger, sepals acute or acuminate, the pedicels longer and somewhat capillary: glabrous, the branches reddish green: lvs. 2- or 3-pinnate, about 8 in. long, the pinnæ 3–5 pairs; lfts. ovate, 3-lobed, membranaceous: fls. small, greenish, pendulous, in lax panicles; sepals 4, ovate-lanceolate, 3-nerved, acute or acuminate; stamens about 14; carpels 5, sessile, 8-ribbed. N. China; very recently described; cult. abroad.

10. *flavum*, Linn. Stout, 2–4 ft., with furrowed st. and creeping stoloniferous rootstock: lvs. large, 2–3-compound; lfts. to $\frac{1}{2}$ in. long, 3-lobed, obovate or obcuneate; infl. compound and compact, the fls. erect

and pale yellow (the anthers bright yellow); sepals small: achenes 6–10, small, 8-ribbed. Eu.

11. *glaucum*, Desf. (*T. speciosum*, Hort.). Sts. erect, round, glaucous, 2–5 ft. high: lfts. ovate-orbicular, 3-lobed; lobes deeply toothed: fls. in an erect panicle, perfect; sepals and stamens yellow: frs. 4–6, ovate, striated, sessile. June, July. S. Eu.

BB. Fls. dioecious or polygamo-dioecious.

c. Achene somewhat inflated, obovoid, and short-stalked.

12. *polycarpum*, Wats. Aromatic, to 3 ft. high, glabrous throughout: lfts. long-stalked, ovate or roundish, serrate, cut or divided, veined beneath: fls. dioecious, in rather close panicles; sepals elliptic or ovate; stamens 16–25, with yellowish anthers: achenes larger, in a dense globose head, short-stalked, obovoid, turgid, tapering into reflexed styles. Sandy streams, coast ranges of Calif. to Columbia River.

CC. Achene flattened and 2-edged, nearly or quite sessile.

13. *occidentale*, Gray. St. to $3\frac{1}{2}$ ft. high, bearing 2 or 3 lvs. which are 2–4-ternate and glandular-pubescent: lfts. thin and glaucous, with rounded lobes: achenes long, slender, thin-walled, 2-edged, ribbed, not furrowed. Colo., northward and westward.

14. *Fendleri*, Engelm. Fig. 3790. Plant 1– $3\frac{1}{2}$ ft. high, rather stout and leafy: lvs. 4–5 times pinnatifid, upper st.-lvs.

3790. *Thalictrum Fendleri*. ($\times \frac{1}{2}$)

sessile; lfts. rather firm, ovate to orbicular, usually with many shallow rounded or acuminate lobes; bases variable: fls. dioecious, in rather compact panicles; stamens many; anthers long: achenes nearly sessile, obliquely ovate, flattened and 1 edge gibbous, 3–4 ribs on each face. July, Aug. S. Colo., westward and southward.

CCC. Achene ovoid, sessile or nearly so, striate or ribbed.

D. Filaments club-shaped or dilated to nearly or quite the width of the anthers.

15. *polygamum*, Muhl. (*T. Cornuti*, Auth., not Linn.). TALL MEADOW RUE. Erect, 3–8 ft. (or more) high, branching and leafy, smooth or pubescent, not glandular: lvs. 3–4 times ternate or terminally pinnate; lfts. oblong to orbicular, bases variable, 3–5 apical lobes: fls. in a long, leafy panicle, polygamo-dioecious; sepals white; filaments broadened when young; anthers short: achenes ovoid, stipitate, 6–8-winged or -ribbed, with stigmas as long, which become curled. July, Aug. Low or wet grounds, Newfoundland and Canada to Fla., westward to Ohio.

DD. Filaments very slender, usually filiform.

16. *dasycarpum*, Fisch. & Lall. (*T. purpurascens*, Auth., not Linn.). Stout and erect with purplish st., 3–7 ft. tall, leafy and branching: lvs. 3–4-ternate; lfts. short-oblong and mostly 3-toothed, pubescent beneath but not waxy or glandular: fls. mostly dioecious but perhaps in some cases polygamous, with purplish

sepals and filaments: achene ovoid, with 6-8 prominent ribs. N. J. to N. D. and Sask. and far southward.—An attractive plant.

17. *venulòsum*, Trel. (*T. confine*, Fern.). St. simple, erect, 10-20 in. high, glabrous, glaucous, bearing 2-3 long-petioled lvs. above the base: lvs. 3-4 times 3-parted; lfts. short-stalked, rather firm, rounded and lobed at the apex, veiny beneath: fls. in a simple panicle, dioecious, small; sepals ovate; stamens 10-20, on slender filaments; anthers oblong, slender-pointed: achenes nearly sessile, 2 lines long, ovoid tapering to a straight beak, thick-walled and 2-edged. S. D. westward and southward in the mountains.

18. *dioicum*, Linn. Rather slender, 1-2 ft. high, glabrous: lvs. 3-4 times 3-parted; lfts. thin, orbicular, several-lobed or revolute, bases variable: fls. in a loose, leafy panicle with slender pedicels, dioecious; stamens much longer than the greenish sepals; anthers linear, obtuse, exceeding their filaments in length: achenes ovoid, nearly or quite sessile, longer than their styles, with about 10 longitudinal grooves. Early spring. Woods, Lab. to Ala., west to Mo.

For *T. anemonoides*, see Syndesmon.—*T. orientale*, Boiss. Low perennial, st. $\frac{1}{2}$ ft. high, flexuose, plant succulose (emitting runners): lvs. triternate; segms. roundish, very obtuse, somewhat 3-lobed: panicle few-fl.; sepals petal-like and persistent, obovate, white, surpassing the stamens; filaments linear: carpels 3-6, linear-oblong, deeply striate, $\frac{1}{4}$ in. long. Asia Minor. Fls. like those of Syndesmon. The plant listed under this name is said to grow 3 ft. high and to have elegant much-divided fern-like glaucous-green lvs. and branching clusters of white fls.—*T. paniculatum*, Hort., is described as a dwarf (1 ft.) with yellow fls. It probably is not *T. paniculatum*, Bess.—*T. paniculatum*, Bess., differs from *T. minus* in the lfts. being trifid from the ovate base, in the very open panicle and the reddish lf.-segms.: habitat doubtful.—*T. præstans*, Hort., listed abroad, is said to be a graceful plant 4-5 ft. high, with yellow and mauve fls.—*T. sulfureum*, Hort., is a hybrid.

K. C. DAVIS.
L. H. B.†

THAMNÓPTERIS (Greek, *bushy fern*). *Poly-podiaceæ*. A generic name for a small group of simple-leaved ferns which cannot properly be separated from *Asplenium*, to which they are here referred (page 414). One species (and a probable variety) is all that is in common cultivation, viz., *A. Nidus*, the bird's-nest fern. Some authors name it under *Neottopteris* (which see).

THÁSPIUM (name modified from *Thapsia*, another genus of the same family). *Umbelliferae*. MEADOW PARSNIP. Glabrous hardy perennials: lvs. ternately divided: umbels terminal, composite; involucre none: fls. yellowish or purple, polygamous; calyx-teeth conspicuous, deciduous; petals acuminate; disk spread out: fr. ovate or ovate-oblong. About 3 species, N. Amer. *T. aureum*, Nutt. St. branched, $1\frac{1}{2}$ ft. high: root-lvs. mostly cordate; st.-lvs. ternate; lfts. ovate to lanceolate, serrate: fls. yellow. June, July. Var. *trifoliatum*, Coult. & Rose, with crenate lvs. or lfts., is a common western form. Var. *atropurpureum*, Coult. & Rose, fls. dark purple. The species is of easy cult. in any ordinary soil. In the wild state the plant grows in at least partial shade. Well-grown plants, especially of var. *atropurpureum*, make attractive specimens. F. W. BARCLAY.

THEÀ (the latinized Chinese name of the tea plant). *Ternstræmiaceæ*. TEA. Woody plants; one species grown for its leaves which yield the tea, the others grown for their handsome flowers and foliage.

Evergreen shrubs or small trees: lvs. alternate, short-petioled, serrate: fls. axillary or sometimes terminal, usually solitary, stalked, nodding; sepals 5-7, persistent; petals 5-7, rarely 9, stamens numerous, more or less connate below; ovary 3-5-celled; styles 3-5, filiform, connate below: fr. a dehiscent caps. with 1 large globose or ovoid seed in each cell.—About 14 species in Trop. and Subtrop. Asia. *Camellia*, differing in its sessile upright fls. with many deciduous sepals, is often united with *Thea*, but from a horticultural point of view it seems desirable to keep the two separate.

The most important member of the genus is *T. sinensis*, cultivated in nearly all subtropical countries and in the mountainous regions of the tropics for its leaves which yield the well-known tea and are an article of great commercial importance. The other members of the genus are ornamental shrubs occasionally grown for their handsome white or pink flowers and the attractive evergreen foliage. They are but little

3791. *Thea sinensis*.—Tea plant. ($\times \frac{1}{4}$)

known in this country and require about the same treatment as *camellia*, which see for culture and propagation.

sinensis, Linn. (*Camellia Thea*, Link. *Camellia theifera*, Griff.). TEA. Fig. 3791. Shrub, sometimes tree, to 30 ft.: lvs. elliptic-lanceolate or obovate-lanceolate, acuminate, serrate, glabrous, sometimes pubescent beneath, 2-5 in. long: fl. white, fragrant, 1-1½ in. broad; petals usually 5. China, India.—Several varieties have been distinguished, of which the following are the most important: Var. *Bohèa*, Pierre (*T. Bohèa*, Linn.). Lvs. elliptic-oblong, obtuse, flat, dark green, to 3 in. long: fls. usually solitary; sepals pubescent inside or glabrous, ciliate, petals 5-6; styles connate below: branches erect. B.M. 998. L.B.C. 3:226. Var. *viridis*, Pierre (*T. viridis*, Linn.). Lvs. oblong-lanceolate, acutish, often concave, light green, to 5 in. long: fls. 1-4; sepals pubescent, ciliate; petals 5-9; styles free: branches spreading. B.M. 3148. L.B.C. 3:227; 19:1828. Var. *cantonensis*, Pierre (*T. cantoniensis*, Lour.). Lvs. oblong-lanceolate: fls. usually terminal, solitary; sepals pubescent inside; petals 7-9; styles free only near the apex. Var. *assamica*, Pierre (*T. assamica*, Mast.). Lvs. oblong-lanceolate, acuminate: fls. 1-4; sepals glabrous inside; petals 7-9; styles free only at the apex.—The black tea, however, and green tea of commerce are not derived from certain varieties, but are the result of different treatment of the lvs. after gathering. For the cult. of tea in N. Amer., see Vol. II, Cyclo. of Amer. Agric.

T. cuspidata, Kochs (*Camellia cuspidata*, Hort.). Shrub, to 6 ft.: lvs. elliptic to lanceolate, thick, long-acuminate, indistinctly denticulate, glabrous, 2-3 in. long: fls. solitary, white, 1½ in. across; petals 6; ovary glabrous. China. G.C. III. 51:261. J.H.S. 38, p. 62, fig. 38.—*T. drupifera*, Pierre=*Camellia drupifera*.—*T. eurypetala*, Booth (*Camellia eurypetala*, Lindl.). Shrub, to 4 ft.: lvs. ovate-lanceolate, silky beneath: fls. white, nodding, axillary, rather small. B.R. 983. L.B.C. 15:1493.—*T. hongkongensis*, Pierre=*Camellia hongkongensis*.—*T. maliflora*, Seem. (*Camellia rosiflora*, Hook.). Shrub: young branchlets pubescent: lvs. ovate, acuminate, 2-3 in. long: fls. pink; petals 5, obovate; ovary glabrous. China. B.M. 5044. Var. *plena* (*Camellia maliflora*, Lindl.). Fls. double, pink.

B.R. 547. L.B.C. 12:1134. B.M. 2080.—*T. reticulata*, Pierre=*Camellia reticulata*.—*T. rosaflorea*, Kuntze=*T. maliflora*, Seem.—*T. Sasangua*, Nois.=*Camellia Sasanqua*.

ALFRED REHDER.

THECOSTÈLE (Greek, *receptacle* and *column*, in allusion to the shape of the gynostegium, the sheath or covering enveloping the female elements). *Orchidaceae*. Epiphytic herbs adapted to the warmhouse. Pseudobulbs fleshy, ribbed, 1-lvd.: lvs. oblong, leathery: scape recurved from the side of the pseudobulbs, bearing a simple raceme: fls. medium-sized, short-pedicelled; sepals equal, free, spreading rather broad; petals linear; labellum connate at base with the column in a broad tube, lateral lobes erect, falcate, almost curled, midlobe spreading, elongate, sinuate, undivided; column apex appendiculate with 2 falcate wings at the side of the stigma; pollinia 2: caps. ovoid, beakless.—About 5 species, Malaya.

Zöllingeri, Reichb. f. Pseudobulbs the size of a nutmeg or narrower: lf. 5-9 in. long, oblong or linear-oblong: scape with the raceme 5-8 in. long: fls. $\frac{3}{8}$ in. diam.; sepals and narrowly linear petals white, blotched with brick-red or crimson; lip yellowish with a pink pubescent front, side lobes subclavate, sigmoid, midlobe broadly obcordate. Lower Burma and Malay Archipelago.

F. TRACY HUBBARD.

THELESPERMA (Greek, *wart*, *seed*; the seeds are often papillose). *Compositae*. Glabrous herbs or subshrubs grown in the warmhouse or greenhouse, and sometimes planted out-of-doors.

Leaves opposite or the upper alternate, linear, often filiform, simply or twice pinnately parted or the upper not divided: head medium-sized, long-peduncled, heterogamous; ray-fls. yellow, in 1 row, neutral; disk-fls. purplish, fertile; involucre in 2 rows, the inner row of bracts campanulate and connate to the middle or more; achenes glabrous, smooth or tuberculate.—About 15 species, Mex. and extra-Trop. S. Amer. The genus may be separated from *Coreopsis* by the form of the involucre, which is in 2 series of bracts with the inner series united to about the middle into a cup, while in *Coreopsis* the 2 series are distinct and united only at the very base. The seeds, especially the outer ones of the head, in *Thelesperma* are often tuberculate.

trifidum, Brit. (*T. filifolium*, Gray). Annual or biennial, 1-2½ ft. high, loosely branching: lvs. twice-pinnate, lobes filiform, outer involucre bracts subulate-linear: rays somewhat spatulate, 3-lobed, disk purple or brown. S. D., Mo., and Neb. to Colo., Texas, New Mex., and N. Mex. B.B. (ed. 2) 3:500.—Probably rare in cult.

hybridum, Voss (*Cosmídium Burrigednum*, Hort.). Fig. 3792. A hardy annual, 1½ ft. high, a hybrid of *T. trifidum* and *Coreopsis tinctoria*, from the latter of which it acquires the brown-purple color of its rays: lvs. bipinnately divided into filiform lobes not wider than the st. This is probably *Coreopsis atropurpurea*, Hort.

F. TRACY HUBBARD.†

THELYMITRA (Greek, *woman* and *cap*, alluding to the hood-shaped column). *Orchidaceae*. Terrestrial herbs with ovoid tubers, occasionally grown in the greenhouse. Lf. solitary, usually with a rather long sheath, linear, lanceolate or rarely nearly ovate: fls. usually several in a terminal raceme, sometimes reduced to 1 or 2, blue, purple, red, or yellow, occasionally with white varieties; sepals and petals nearly equal, spreading; labellum similar; column erect, broadly winged, the wings variable, sometimes extended into a broad lobed hood over the anther, lateral lobes often penicillate or crested: caps. erect, obovoid or oblong, beakless. About 30 species, Austral., New Zeal., New Caledonia, and Malaya. Cult. similar to that of *bletia*. None of the species is in common cult., but a number of them are of interest to orchid fanciers.

T. cárnea, R. Br. St. slender, often flexuous, 6-12 in. high: lvs. narrow-linear: fls. 1-3, pink, sepals and petals oval-elliptic, oblong or obtuse, about 4 lines long. Austral.—*T. izioides*, Sw. St. usually more than 1 ft. high: lvs. long-linear or linear-lanceolate, flat or channeled, with 1 or 2 shorter ones: fls. blue, pedicellate, usually forming a raceme 4-6 in. long; sepals, petals, and lip elliptic-oblong, 9-10 lines long. Austral.—*T. longifolia*, Forst. (*T. Forsteri*, Sw., *T. graminea*, Lindl. *T. pauciflora*, R. Br.). Usually about 1 ft. high: lvs. long and narrow: fls. blue, lilac, or pink, rather large, several to a raceme, column produced into a broad hood, usually conspicuous from its dark color. Austral.—*T. variegata*, Lindl. St. not very stout, 1 ft. or more high: lvs. with a villous sheath, blade linear, glabrous, with a much dilated base: fls. 2-4, purple, large; sepals and petals lanceolate, shortly acuminate or acute, $\frac{3}{4}$ -1 in. long, variegated. Austral.—*T. venosa*, R. Br. St. 1-2 ft. high: lvs. long and narrow: fls. blue, 6-10; sepals and petals $\frac{1}{2}$ -¾ in. long; column broadly winged. Austral.

F. TRACY HUBBARD.

THEOBRÔMA (Greek, *food of the gods*). *Sterculiaceae*. Here belong the trees that produce the seed from which chocolate and cocoa are derived.

About a score of small trees in Trop. Amer., with large simple thick and strongly nerved entire lvs., and small fls. which in at least some species are borne laterally on the branches rather than in axils: calyx deeply

3792. *Thelesperma*
hybridum.
(Flower $\times \frac{3}{4}$)

5-parted or -lobed; petals 5, mostly clawed or narrowed below; fertile stamens 5, opposite the sepals; ovary sessile and 5-celled, many-ovuled, the style filiform: fr. a large woody drupe or pod, with seeds imbedded in the pulp. The species of prime economic importance is *T. Cacao*, but other species are probably concerned in the production of cocoa, and the natural history of the group is yet confused. The word "cacao" (pronounced *ka-kow*) is the name of the plant and the unmanufactured product of it; "cocoa" is the manufactured product, produced from the bean-like seeds, chocolate being the chief commercial commodity. (Coco is a

very different plant: see *Erythroxylon*.) The beans are washed or fermented, or both, to remove the mucilaginous substance with which they are surrounded or coated with clay to make them moisture-proof, to prevent decay, and preserve the aroma.

The common cacao is *T. Cacao*, Linn., native apparently in Cent. and S. Amer. It is a wide-branching evergreen tree, reaching 20-25 ft. in height (or somewhat more in the wild), with pubescent twigs and alternate oblong-oval or elliptic-oblong entire short-petioled lvs., the blade 6 in. long more or less, rounded at base and abruptly acuminate at apex, with strong midrib and paired or somewhat alternate arching side veins: fls. small, in fascicles directly on the bark of the trunk and main branches, about $\frac{3}{4}$ in. across when expanded, on slender pedicels $\frac{1}{2}$ in. or more long; calyx rose-colored, with acuminate segms.; corolla yellowish, the long petals with a stalk-like claw and expanded blade: fr. or "pod" 1 ft. or less long and mostly 4 in. or less in diam., about 10-ribbed, red,

3793. *Theobroma Cacao*, chief source of chocolate. a, b, flowers, enlarged; c, fruit, much reduced.

yellow, purplish, or brown, elliptic-ovoid in form, the rind thick, hard, and leathery; cells 5, each with 5-12 "beans" in a row imbedded in a white or pinkish acid pulp; the pods will average about 20-40 good beans; these flat brown or purple beans or seeds, each an inch or more across, constitute the commercial cacao, from which the products are manufactured. For an account of the cult. of cacao, see *Cyclo. Amer. Agric.*, Vol. II, pp. 224-6. There is a large literature on the subject.

The estates devoted to the culture of the plant are usually known as "cacao plantations" and are largely on the increase in all suitable climates, owing to the increased demand for the manufactured article in the different forms in which it is now prepared for consumption. The larger proportion of commercial cacao is produced by *Theobroma Cacao* (Fig. 3793). Other species native to Central America and the West Indies are *T. pentagona*, *T. speciosa*, *T. angustifolia*, and the closely related *Tribroma bicolor*.

In vigor of growth and productive capacity, *Theobroma pentagona* resembles to a very large degree the generally cultivated varieties of *T. Cacao*, but it differs in the flowers, in the size of the beans, and especially in the shape of the pods. The beans are larger in size

than those of *T. Cacao*, fully equal if not superior in flavor, and are capable of being worked up in the same way as the commoner species. This kind is known on the mainland as "Alligator" cacao, from the fancied resemblance of its skin to the hide of an alligator. The outside of the pod is soft and easily broken, and does not afford such good protection to the interior as the harder shell possessed by *T. Cacao*. In Nicaragua, *T. Cacao* and *T. pentagona* are grown together, and the produce is mostly a mixture of the two species. From the presence of *T. pentagona*, it is possible that hybridization has taken place between two species. It has been noted that the pods of *T. Cacao* produce much larger seeds or beans in Nicaragua than in countries where this species is not grown in company with *T. pentagona*: and the beans of the two species are almost impossible to distinguish when cured together. The product of Nicaraguan plantations also requires much less time for fermentation than the produce of Grenada, Trinidad, or Venezuela, some forty-eight hours being the usual period, while more than four times that number of hours will be required for the proper fermentation of the produce of the last-mentioned countries.

The "Monkey cacao" of the mainland is produced by *Theobroma speciosa*. This is never made into market cacao, as it is very inferior in quality and has a disagreeable flavor. The pods are hard, much corrugated, warted, and of a dirty brown color when ripe.

Many names have arisen for the varieties of *Theobroma Cacao* which are in cultivation, as many as forty having been listed by a Trinidad cultivator of large experience. Looking at the matter from a practical point of view, all these are merely strains of the one species, produced by natural cross-fertilization of the older types. According to Hart's "Cacao," Trinidad, 1900, there are but three major strains or classes of *T. Cacao*, respectively, "Criollo," "Forastero," and "Calabacillo." The type of the first is found indigenous in Trinidad and various places on the mainland, its distinctive character being its bottle-necked pod, with a thin skin and finely ribbed exterior, together with its white or whitish seeds or beans, which are mild in flavor and somewhat rounded in form.

The characters of "Forastero" are its roughly corrugated or verrucose pod, containing large flattish seeds of a purplish color. It is a tree having greater vitality than "Criollo," and gives a much larger crop. "Forastero" means foreign, and this type is said to have been found on the mainland of South America, whence it was imported to Trinidad by Arragonese Capuchin Fathers about 1757. (De Verteuil, "History of Trinidad," 1884.)

"Calabacillo" is the third form, its chief characteristics being the vigor of its growth and its small flat and strongly flavored bean. By some it is considered as a degraded form of Forastero.

While the above gives a brief sketch of the chief characters of the principal types, it must be understood that there are varieties intermediate between the forms; in fact, on the larger number of estates it is impossible to find any two trees exactly alike in all their botanical characters, occurring, without doubt, from the uninterrupted cross-fertilization which has taken place. Still, each country appears to maintain certain characters more permanent than others, and thus secures for itself a name upon the markets of the world. It is probable that this is due, in a measure, to the unconscious preference taken by some to distinctive features of the produce by the continuous cultivation of a fairly

fixed strain which has arisen. It may also be due in some measure to the influence of climate and environment. Certain it is, however, that there are today strains of cacao which are possessed of distinctive characters, not readily produced by any process of preparation in places other than that in which they are grown. A fine set of illustrations of varieties common to different countries has been published in a work by Paul Preuss, who traveled in cacao-producing countries on behalf of the German government.

These different brands are bought by manufacturers and blended to suit their particular market, but there are certain kinds possessing special flavor which are readily sold at high prices. The value of the commercial product fluctuates and the price has marked variations due to many causes. Whether this results from increased production or from a deterioration in the quality cannot be ascertained. It is clear that if cultivators grow cacao for seed without regard to the best rules of selection, the quality must deteriorate. What mitigates this fact is that all the cacao world has, up to a recent date, followed the same practice. The process of grafting, to which the cacao tree readily submits, as has been proved in Trinidad, will enable operators to make large fields of the choicer varieties, and it may confidently be expected that in a few years a great improvement will be shown in the various grades placed upon the market. (For a recent account of budding, see Wester, Philippine Agric. Rev., 1914, p. 27.) But little cacao is manufactured in the countries where it is grown.

Chocolate is the term used for sweetened and hardened preparations of the roasted and ground cacao bean, with the larger proportion of the original fat retained, while the so-called "cocoa" preparations are the same material in fine powder, sweetened or unsweetened, but with the greater proportion of the cacao fat extracted. This fat, when clarified, is a pure white substance, almost as hard as beeswax, and is used in many pharmaceutical preparations. Chocolate and cocoa are both made from the beans or seeds of *Theobroma Cacao* and *T. pentagona*, and differ only in the method of preparation.

The word "cocoa" is a market corruption of the original Spanish "Cacao," which was adopted by Tournefort as a generic name but has since been displaced by the Linnaean *Theobroma*.

The plant known as *Theobroma bicolor* has recently been made the type of a new genus (*Tribroma bicolor*, Cook) on account of distinctly different habits of fruiting and flowering and structural differences in the flower (O. F. Cook, Journ. Wash. Acad. 5:287-289, 1915). The leaves are large, and in the juvenile stages of growth are broadly cordate in form, and assume the mature or oblong form only on reaching the third or fourth year's growth. The pods are oval, ribbed and netted, hard and woody, with an outer shell $\frac{1}{2}$ inch in thickness which can be cut only with a saw. The seeds are oval, much flattened, with a dark, hard, and smooth exterior. The interior is white, and has a somewhat nutty flavor. They are used in sweetmeats in the same way as almonds, but cannot be made into commercial cacao, suitable for the manufacture of chocolates. This species is very widely distinct from any of the varieties of *T. Cacao* which produce commercial cacao. The produce of *T. bicolor* is known in some parts of Central America by the names of "Wariba," "Tiger," and "Patashte" cacao. See also Cont. Nat. Herb., vol. 17, pt. 8, for branching and flowering habits of cacao and patashte.

J. H. HART.

L. H. B.†

THEODÒREA (probably a personal name). *Orehi-dacæ*. One Brazilian orchid, *T. gomezoides*, Rodr., of botanical interest but very little known in cult. By some it is referred to *Gomezia*. Rolfe describes it as having "the general habit of some small slender oncid-

ium, about 5-6 in. high, but the fls. are borne in slender arching racemes of about 6-12 each. The sepals and petals are subconnivent, lanceolate, acute, 4-5 lines long, and light green in color, with a broad dark brown line toward the base. The lip is oblong-ovate, acute, somewhat reflexed at the apex, and white, with an orange-buff blotch in the center. It appears to be a free-growing little plant, and its appearance in cult. is interesting."

THEOPHRÁSTA (named for Theophrastus, a Greek naturalist and philosopher, 370-285 B.C.). *Myrsinacæ*; by Mez separated in the family *Theophrastacæ*. Glabrous shrubs, adapted to the warmhouse.

Stem stout, erect, rather simple: lvs. somewhat terminally clustered, spreading, very short-petioled, linear-oblong, spinose-dentate, netted-veined; fls. hermaphrodite, rather large, in short many-fld. racemes, white; calyx 5-parted, segms. ovate; corolla cylindrical-campanulate, 5-lobed at the top, lobes rotundate; stamens 5, staminodes 5; ovary ovoid: fr. globular, apple-shaped, fleshy, many-seeded.—Two species according to Mez, Pflanzenreich, hft. 15 (IV. 236a). W. Indies. The chief technical differences between *Theophrasta* and *Clavija* are in the fls. and frs. In *Theophrasta* the corolla is cylindrical and shallowly 5-lobed; staminodia attached on the base of the corolla: fr. large and many-seeded. In *Clavija* the corolla is subrotate and deeply 5-cleft; staminodia attached on the tube of the corolla; fr. 1- to many-seeded. See *Clavija*.

Jussieui, Lindl. (*T. densiflora*, Deane.). Small slender tree, 4-8 ft. high, trunk spiny, 1 in. thick: lvs. large, elongate, linear-lanceolate, gradually narrowed toward the base, about $1\frac{1}{2}$ ft. long, margin sinuate-serrulate, serrulations spinulose, both surfaces lepidote-punctate: infl. many-fld., tomentose with chestnut-brown hairs: fls. white; sepals narrowly rotundate or acutish at apex; corolla fleshy; staminodes dark brown, papillose. Haiti and Santo Domingo. B.M. 4239.

americana, Linn. (*T. fusca*, Deane.). Subshrub 1-3 ft. high: st. simple, with ash-gray bark: lvs. elongate, linear-lanceolate, gradually narrowed toward the base, 18-20 in. long, about 2 in. wide, margin with small teeth: infl. many-fld., very densely cylindrical raceme, fuscous-tomentose: fls. dull brown, becoming black; sepals rotundate at apex; corolla urceolate; staminodes slightly emarginate, pulvinate-fleshy. Haiti and Santo Domingo.—Probably rare in cult.

T. imperialis, Lindl. = *Martiusella imperialis*.—*T. latifolia*, Willd. = *Clavija latifolia*.—*T. longifolia*, Jacq. = *Clavija longifolia*.—*T. macrophylla*, Lindl., not Link = *Clavija grandis*.—*T. minor*, Lindl., is offered in the trade; it is some species of *Clavija*.

F. TRACY HUBBARD.†

THERMÓPSIS (Greek, *lupin* and *like*). *Leguminosæ*. Hardy perennial herbs.

Rhizome usually repent, sending up annual, erect, simple or branched sts., sheathed at their base: lvs. alternate, digitately 3-leafleted; stipules free, lf.-like: fls. rather large, yellow, rarely purple, in terminal racemes or disposed opposite the lvs.; pedicels solitary; calyx narrowly campanulate, teeth or lobes subequal; standard suborbicular; wings oblong; keel equaling or scarcely longer than the wings; stamens free: pod sessile or short-stipitate, linear-oblong or ovate-inflated, straight or curved.—About 18 species, N. Amer. and N. and E. Asia. They are not particular as to land or position, but do best in a deep light well-drained soil. They are generally deep-rooted plants and endure drought very well. Prop. may be effected by division, especially in *T. montana*, *T. fabacea*, and *T. rhombifolia*, which spread extensively by the root, but in general the better way is by seed, although the seed is rather slow to germinate and should be sown as soon as ripe or in the spring with some heat.

A. Pod strongly recurved.

rhombifolia, Richards. Plant about 1 ft. high, branched: lfts. usually oval or obovate, $\frac{1}{2}$ -1 in. long:

fls. in a compact spike: pod glabrous. June, July. Western states. B.B. 2:265.

lanceolata, R. Br. (*Podalyria lupinoides*, Willd.). Sts. 6-12 in. high: lvs. nearly sessile, the lower and uppermost ones often simple; lfts. oblong-lanceolate, silky-puberulent on both surfaces; stipules lanceolate, half as long as lfts.: fls. geminate or somewhat verticillate, bright yellow. Siberia and Alaska. B.M. 1389.

AA. Pod straight or only slightly curved at the apex.

B. Plant 3-5 ft. high.

caroliniana, Curtis. St. stout, smooth, simple: lvs. long-petioled; lfts. obovate-oblong, silky beneath; stipules large, clasping; racemes 6-12 in. long, erect, rigid, many-flid.: pod 2 in. long, erect, villous, and hoary. June, July. Mountains of N. C.

BB. Plant 1-3 ft. high.

c. Stipules longer than the petiole.

montana, Nutt. Plant 1½ ft. high, somewhat silky-pubescent: lfts. oblong-obovate to oblong, 1-3 in. long: fls. in long spikes: pod straight, erect, pubescent. May, June. Western states. B.M. 3611. B.R. 1272 (both erroneously as *T. fabacea*).—Sometimes called "buffalo pen" in the West.

cc. Stipules shorter than the petiole.

d. Racemes axillary.

fabacea, DC. Resembles *T. montana* and has possibly been confounded with it in the trade. It differs in having more spreading pods and larger and more compressed seeds. May, June. Siberia.

dd. Racemes terminal.

mollis, Curtis. St. erect, branched, 2-3 ft. high, pubescent: lfts. obovate-oblong, 1-2 in. long: racemes 6-10 in. long: pod slightly curved at the end, 2-4 in. long. May-July. Va. and N. C.

fraxinifolia, Curtis. Sts. 1-3 ft. high: lfts. 3, oblanceolate to elliptic, oval or lanceolate, glabrous or nearly so; stipules linear to linear-lanceolate: fls. in a loose raceme 4-12 in. long: pod falcate, linear, pubescent, 2-4 in. long. Mountains of N. C. and Ga.

F. W. BARCLAY.

F. TRACY HUBBARD.†

THESPESIA (Greek, *divine*; application doubtful). *Malvaceæ*. Trees or tall herbs, grown in the warm-house, and planted in warm regions.

Leaves entire or angulate-lobed: fls. usually yellow, showy; calyx truncate, minutely or bristle-toothed, rarely 5-cleft; ovary 5-celled: caps. woody-coriaceous, loculicidally 5-valved.—About 10 species, Trop. Afr., Asia and the islands of the Pacific, and 1 from Porto Rico. They have the aspect of hibiscus and may be distinguished by the confluent stigmas, more woody caps., and the obovoid compressed seeds.

populnea, Soland. A small tree with the younger portions covered with peltate scales: lvs. long-petioled, ovate, cordate, acuminate, 3 in. across: fls. axillary, 2-3 in. across, yellow. Trop. Asia, Afr., and the islands of the Pacific.—Cult. in S. Calif., where it is said to succeed only in warm and moist locations. The fls. are described as varying from yellow to purple. A common tree on tropical seacoasts, reaching 30-40 or even 50 ft., with dense top, blooming all the year; the inner bark yields a fiber, and the wood is durable and useful.

T. grandiflora, DC. Tree, 30-45 ft. high: lvs. ovate, subcordate, apex subacuminate: fls. purple or red, 4-5 in. diam. Porto Rico. The wood is used in Porto Rico for furniture and other purposes and it is recommended for ornamental uses.

F. TRACY HUBBARD.†

THEVETIA (named for André Thevet, a French monk, 1502-1590). *Apocynaceæ*. Glabrous small trees or shrubs which are grown in the warmhouse, or out-of-doors in the extreme South.

Leaves alternate, 1-nerved or lightly feather-veined:

fls. large, yellow, in terminal, few-flid. cymes; calyx 5-parted, many-glanded inside at the base, segms. acute, spreading; corolla funneliform; lobes broad, twisted; disk none; ovary shortly or deeply 2-lobed, 2-celled: drupe broader than long, 2-celled.—About 10 species, Trop. Mex. southward to Paraguay.
